material is to be inoculated directly into animals, white rats are next best, and guinea-pigs and monkeys frequently yield no results

ANIMAL VECTORS

Cases have been reported in which the animal vector has been other than the rat. Our cases are unusual in that the animal transmitting the disease was the dog. In one case the ease with which the causative organism invaded the tissues is of particular interest because there was no noticeable scratch or abrasion of the skin, yet a typical local lesion developed.

Yamada,²⁷ Sano²⁸ and Mock and Morrow²⁹ have reported cases following the scratch or the bite of a cat. Smallwood³⁰ reported a case, diagnosed on clinical signs, following the bite of a young pig. Cazamian³¹ recorded a case following the bite of a dog and mentions references in his article to other case reports following the bite of a cat, a mad dog, a squirrel, a ferret or a weasel. Burnford³² has also recorded a case in which the subject was bitten by a ferret. A case in which Dick and Tunnichiff³³ found *Streptothrix putorii* gave a typical history of rat-bite fever following the bite of a weasel.

MORPHOLOGY OF THE SPIRILLA

The organism found by us agrees in morphology with that described and shown in photomicrographs by others. The forms varied in length from 1.5 to 6 microns with about 1 spiral per micron. The motion, as studied under dark field examination, was extremely rapid. As Francis³⁴ points out, a person searching for spirochetes and accustomed to the slow backward and forward motion of *Spirochaeta pallida* might fail to recognize the significance of *Spirochaeta morsus-muris* with its darting forward motion. When the preparation had stood for some time or the organisms had become obstructed by clumps of platelets, definite flagella could be seen. These were further demonstrated by Burri's india ink method. Other flagella stains were tried, namely, Adachi's, Bailey's and Zettnow's, without success. Only a single flagellum was seen at each end of the organism.³⁴

CONCLUSIONS

- 1 From two cases of rat-bite fever, *Spirillum morsus-muris* has been isolated.
- 2 The animal vector was apparently the dog.
- 3 The experimental disease has been produced in dogs.
- 4 Kahn tests were strongly positive on both patients and the experimental dog that survived, while the Kolmer Wassermann reaction was usually negative or weakly positive.
- 5 A patient suffering with dementia paralytica was inoculated with the spirilla and developed a typical lesion and symptoms of rat-bite fever.

6 Flagella were demonstrated only with Burri's india ink method.

7 The mouse proved to be a better diagnostic animal than the guinea-pig.

8 In one case, infection was contracted when no skin abrasion was noted, suggesting ease of penetration of the organism.

9 The clinical course of the disease showed marked variation.

10 A course of from three to six treatments with arspenamine seems advisable.

EXTENSION OF MALIGNANT TUMORS OF THYROID INTO GREAT VEINS AND RIGHT HEART

WILLIAM L. HOLT, JR., M.D.
BOSTON

Malignant tumors of the thyroid gland may involve neighboring veins and extend as tumor thrombi into the superior vena cava and right side of the heart. Four cases have been reported and are here assembled. This report adds another case studied by me. It is unique in that the tumor thrombosis invaded both venae cavae and the right auricle.

GENERAL CONSIDERATIONS

Malignant tumors of the thyroid gland constitute between 1 and 2 per cent of all goiters and are found about once in every thousand necropsies in the United States. The greatest number of cases occur in the fifth decade. Women are afflicted in from two thirds to three fourths of all cases.¹ Adenomatous goiter precedes malignant conditions of the thyroid in more than 90 per cent, and over 90 per cent is of epithelial origin.² Clinical signs of toxic adenoma are present in about half of all cases. Exophthalmos is present in very few cases. A malignant condition is an accidental and unexpected finding at operation or in the pathologic laboratory in over half of the cases.^{1b}

Operative removal results in about 6 per cent immediate mortality, and an additional 60 per cent of the patients die within three years of recurrence. An additional 20 per cent have a recurrence as late as thirteen years after operation.³ When the diagnosis can be made before operation, the tumor has broken through the capsule of the gland and complete removal is only rarely possible. Papillary cystadenomas, adenocarcinomas and small alveolar carcinomas are amenable to radiation therapy and fortunately constitute about 83 per cent of all malignant tumors of the thyroid.⁴ Sarcomas and so-called mixed types are rapidly and universally fatal. Malignant adenomas treated by combined surgery and radiation yield a 25 per cent three year cure rate, whereas papillary cystadenomas give a 50 per cent three year cure. Results depend on the

type of tumor. Those tumors which most closely resemble the structure of the normal thyroid have the best prognosis. Treatment should consist of combined surgery and radiation or radiation alone.

Metastases are in evidence in 20 per cent of necropsies on patients showing a malignant condition of the thyroid gland and take place chiefly by way of the blood stream.⁶ Metastases involve the lungs and mediastinum in about half of these cases, and the bones are the next most frequent site.

The tendency of thyroid tumors to extend into the neighboring veins has been reported by Graham in this country and by Billroth, Kaufmann and others in Europe.⁷ Graham and Weinlechner report invasion of the thyroid veins only. Billroth, Kaufmann, Springer

nodular mass in the neck, edema of the upper half of the body, marked cyanosis of the face and engorgement of the superficial veins of the neck. She died two months later.

Autopsy showed a mass the size of two fists in the left lobe of the thyroid with extension into the thyroid, internal jugular, subclavian and innominate veins on both sides and into the superior vena cava and right auricle. The lumen of these veins was distended and completely occluded by the tumor thrombi. The chamber of the right auricle was filled with the polypoid tumor mass. Metastases were present in the cervical lymph nodes, mediastinum and lungs. Microscopic examination confirmed the gross changes.

2 Billroth's case, quoted from Springer.⁷ A woman, aged 51, with a large nodular goiter was found at operation to have neoplastic thrombi of the neck veins. At autopsy the tumor thrombi were found to extend from the thyroid into the superior vena cava and cavity of the right auricle.

3 Springer's case. M. M., a woman, aged 44, in February 1898 had noticed a lump in the left side of the neck for a year. She had suffered a gradual loss of strength and increasing dyspnea for several months and had been aphonic for four weeks. She showed a nodular mass the size of two fists in the thyroid region, increased retrosternal dullness, edematous swelling of the face and arms, paralysis of the vocal cords, stenosis of the trachea, and a loud systolic heart murmur at both the apex and the base. Choking attacks made a tracheotomy necessary. During this operation, tumor thrombi of the tracheal veins were noticed. The patient bled profusely from ulcerated areas in the larynx and died two months later, very anemic and poorly nourished.

At autopsy the patient presented sarcoma of the thyroid penetrating and stenosing the trachea, involving the pharynx, larynx and esophagus and extending as venous thrombi from the thyroid veins into both innominate and subclavian veins, the superior vena cava and the chamber of the right heart. A tumor thrombus hung as a polyp from the orifice of the superior vena cava, extended through the tricuspid opening to the bottom of the cavity of the right ventricle, then bent upward to the conus arteriosus, 10 cm long in all. On contraction of the ventricle the tumor polyp must have been pushed against the pulmonic valve ring. The hypertrophy of the right heart was not unusual for an anemic patient. The left ventricle was also hypertrophied. No metastases were found elsewhere.

4 Wylegischann's case. K., a woman, aged 52, seen in 1926 by Prof. N. K. Gorjajew, presented at that time a greatly enlarged nodular tumor of the thyroid. The cervical lymph nodes were enlarged and hard, and the thyroid tumor was fixed to surrounding structures. There was edema and cyanosis of the upper half of the body and dilatation of the superficial veins of the trunk. Malignancy of the thyroid and obstruction of the superior vena cava were diagnosed. Increasing cough and dyspnea developed and the patient died in November 1927.

Necropsy showed a large nodular thyroid tumor that had invaded the adjacent sternothyroid and sternohyoid muscles and the cervical and bronchial lymph nodes and had extended as tumor thrombi through the thyroid, the internal jugular and innominate veins, the superior vena cava and upper portion of the azygos vein and into the right auricle. The cavity of the latter was markedly enlarged and almost completely filled with a tumor thrombus, which was firmly attached to the posterior wall of the auricle. There was a tumor nodule on the posterior tricuspid leaflet. The atrioventricular opening was partly obstructed by the tumor mass. Microscopic examination of the tumor showed it to be a carcinoma arising from a malignant nodule in the thyroid gland.

5 Author's case. E. B. M., a white man, aged 72, native born, admitted to the Western Pennsylvania Hospital, Jan. 7, 1931, in the surgical service of Dr. F. R. Bailey, complained of a painful swelling of the neck for one year and choking attacks for three months. His family history was of interest in that his mother had had a swelling of the neck and choked to death at the age of 77. The patient's enlargement of the neck had been steadily increasing for a year, but according to the patient it had not been preceded by any goiter. He had lost 18 pounds (8.2 Kg.) within the year, had become nervous and had frequent severe headaches and attacks of weakness.

Fig. 1 (case 5)—Right side of the heart, showing tumor thrombi occluding the venae cavae and filling the right auricle. A, entrance of superior vena cava into the right auricle; B, tumor mass in the inferior vena cava; C, mass in the right auricle.

and Wylegischann report extension of the tumor thrombi into the superior vena cava and the right side of the heart.

CASES COLLECTED FROM THE LITERATURE

1 Kaufmann's case. A woman, aged 58, with a history of goiter since the age of 30, had noticed an increase in the size of the goiter during the six months preceding admission to the hospital. She complained of great dyspnea and also difficulty in swallowing. On examination she presented a large

Ein Fall von ausgebreiteter Schilddrüsenkrebswucherung durch die Blutgefäße in den rechten Vorhof. *Frankfurter Zt. chr. f. Path.* 40: 51-63, 1930.

On physical examination he was found to have a pulsating nodular mass the size of two fists in the anterior and lateral portions of the neck. The mass was attached to the trachea but not to the skin. There was a soft systolic murmur at the apex of the heart. The rest of the positive physical changes were not noteworthy. The basal metabolic rate was plus 22 per cent. Roentgen examination of the chest showed increased width of the mediastinal shadow interpreted as a probable mediastinal mass. A diagnosis was made of inoperable carcinoma of the thyroid with extension into the mediastinum. High voltage roentgen therapy was given in the physical therapy department by Dr. Heinz Langer. The mass in the neck responded well and the patient was discharged to the physical therapy outpatient department after ten days, much improved.

Treatment was continued for six months while he was an outpatient. About 3,200 roentgens of filtered rays (0.5 mm of copper and 30 mm of aluminum, 200 kilovolts) was given by cross firing at the tumor in the neck. Half of this dosage probably reached the tumor tissue. Over the mediastinum 2,400 roentgens was given. The spine was given 1,600 roentgens. When seen in March 1931 the mass in the neck had decreased 75 per cent in size, the patient had gained 8 pounds (3.6 Kg) and coughing had stopped. In June 1931, six months after beginning treatment, the patient felt perfectly well and the mass in the neck was smaller and softer. Treatment was stopped because the patient insisted that he was cured and was unwilling to come in for treatment. He did return in August 1931 for another roentgen examination of the chest which showed a decrease in the width of the mediastinal shadow. Barium by mouth at this time showed no retention in the esophagus, and the trachea was not displaced. The patient was not seen again until January 1933, when he came in answer to a letter. At this time a basal metabolic rate determination was done and found to be minus 13 per cent. A small dose of dried thyroid gland substance ($\frac{1}{8}$ grain [0.013 Gm] three times a day) was given him. He had gained 19 pounds (8.6 Kg) and there was no evidence of renewed activity of the small mass in the neck. The patient returned a month later, complaining of dyspnea. The heart action was rapid but regular. The dosage of thyroid was decreased. The size of the neck seemed unchanged.

Four days later, February 26, the patient was readmitted to the surgical service of Dr. F. R. Bailey. The patient complained of severe dyspnea, a generalized swelling of the neck, weakness and coldness of the right arm and edema of the legs. The right arm had been growing weak for a month. The edema of the legs had been present for three weeks. All symptoms, but especially the dyspnea, had become much worse in the four days preceding admission. On physical examination he showed great respiratory distress and marked cyanosis of the head, neck and right arm. There was a small mass in the right lobe of the thyroid and the surface of the gland was nodular. The examination of the lungs showed nothing noteworthy. No enlargement of the heart or mediastinum could be made out. No murmurs were heard. The heart rate was 84 and the rhythm regular. The superficial veins over the left side of the chest anteriorly were noticeably but not remarkably enlarged. Those of the right side of the chest anteriorly were less notable. There was no enlargement of the superficial vessels of the abdomen. Dulness was present in the flanks and there was marked pitting edema of both legs. The right arm and hand were cold and bluish, sensation in this region was slightly impaired, and movements of the hand were very slowly executed.

Vigorous supportive treatment for circulatory failure was given but the pulse rate, dyspnea and cyanosis rapidly increased. The blood pressure was well maintained, being 120 systolic, 60 diastolic, as compared with 130 systolic, 70 diastolic during his previous admission. Dr. T. T. Sheppard saw the patient in consultation on the second day and raised the question of probable abdominal as well as mediastinal metastases. The patient died on the third day when the pulse rate and blood pressure fell.

Autopsy was performed twelve hours after death by Dr. W. S. Nettroir, and his observations will be given in some detail.

A small firm, immobile mass was felt in the region of the sternoclavicular notch. Dulness was present on percussion of

the dependent portions of the thorax. There was flatness to percussion in the flanks and the abdomen was markedly distended. The inferior border of the liver was 3 cm below the right costal margin. There was marked edema of both legs. Each pleural cavity contained about 500 cc of clear straw-colored fluid. Old pleural adhesions were present. The right pleura was firmly attached to a mediastinal mass, which occupied the posterior mediastinum, penetrated the pericardium and completely encircled the great vessels. The lumen of the superior vena cava was distended and occluded by a tumor thrombus, which continued into the right auricular chamber, was prolonged downward into the inferior vena cava, upward into the innominate veins of both sides and into the right subclavian, internal jugular and thyroid veins. In the inferior vena cava the mass had extended down to the level of the entrance of the hepatic veins. Just below the level of the hepatic veins there was a large mural tumor thrombus firmly attached to the wall of the inferior vena cava. The mediastinal mass was continuous with the lower pole of the right lobe of the thyroid. Very small blood-filled clefts were visible, traversing the tumor thrombi in both venae cavae, suggesting canalizations. Polypous tumor tissue hung free in the chamber of the right auricle, almost completely filling it. The tumor

Fig. 2 (case 5) —Section of tumor mass

masses were adherent to the wall of the cavity in several places. The valves were not involved. There was moderate cardiac hypertrophy, especially of the left ventricle.

On section all portions of the tumor, including the tumor mural thrombus in the inferior vena cava, had a uniform pinkish white opaque appearance and firm consistency. The remainder of the thyroid gland showed adenomatous changes. No further metastases were found. The microscopic examination showed adenocarcinoma of the thyroid arising from a malignant adenomatous nodule. All portions of the tumor, including the portion in the inferior vena cava, were of essentially identical structure.

COMMENT

The changes found at autopsy in the case reported here justify interesting observations on the development of physical signs and symptoms, especially as related to the mechanics of circulation. The cyanosis and weakness of the right hand and arm were probably due to extension of the mass into the right subclavian vein, blocking the entrance to the right internal mammary vein and thereby much of the collateral venous return.⁸ The left internal mammary vein was still unobstructed at death, which accounts, perhaps, for the greater prominence of the superficial veins over the left side of the chest anteriorly. The edema of both legs was doubtless due to obstruction of the inferior vena cava. The immediate cause of death was cardiac

⁸ Hallett, C. H. Collateral Circulation After Obstruction of the Venae Cavae. *Edinburgh M. & S. J.* 69: 269-292, 1848.

failure due to obstruction of both venae cavae. Autopsy indicated that the rising heart rate was an effort to compensate for falling stroke volume secondary to obstruction to venous return. It is remarkable that the patient was able to walk into the hospital three days before he died. It seems unlikely that the tumor grew much more rapidly in the last few days of the patient's life. It seems more likely that a much smaller cardiac output is necessary to permit moderate activity than is generally thought. The administration of thyroid begun a month before death was probably not a factor in the terminus.

This case is unique in that the tumor thrombosis of the inferior vena cava occurred by direct extension from a site above the level of the heart.⁹ Simpson collected all the reported cases of tumor thrombosis of the inferior vena cava up to 1924. In all cases the primary site of the tumor was below the level of the heart.¹⁰ He stresses the fact that edema of the legs was almost invariably present but that dilatation of the superficial veins of the abdomen was noted in less than half of the cases.

Fishberg¹¹ was the first to make the diagnosis of tumor invasion of the right auricle during life. He reported two cases in 1930 in which auricular flutter and fibrillation developed in the presence of known mediastinal tumor and led to this diagnosis, later confirmed at autopsy. The involvement of the right auricle and inferior vena cava was not even thought of in our own case. The cardiac rhythm remained normal. The edema of the lower extremities was thought to be due to circulatory failure, probably of myocardial origin in spite of little evidence of organic heart disease.

The absence of further metastases was an unexpected finding. Tumor polypoid masses hung free in the right auricle. It is hardly conceivable that no tumor cells broke loose to enter the lungs. A diligent search was made in the lungs, including fifty sections that were examined microscopically, but no evidence of metastases were found. This observation raises the question as to how often tumor emboli are completely resorbed from the lungs.

CONCLUSION

1 Malignant thyroid tumors have a tendency to invade adjacent veins and extend in them toward and also away from the heart.

2 Four cases of extension of thyroid tumor thrombi into the great veins and right heart have been collected from the literature.

3 A case of tumor thrombosis of the right auricle and both venae cavae is probably a unique finding. Some observations are made on the development of signs and symptoms and the mechanics of the circulation.

MALIGNANT ULCERATIVE GONOCOCCIC ENDOCARDITIS

FATAL FIVE DAYS AFTER APPEARANCE OF
CARDIAC INVOLVEMENT

H. LEBARON PETERS, M.D.

AND

BENJAMIN HORN, M.D.

Pathologist and Assistant Pathologist Respectively
Bridgeport Hospital

BRIDGEPORT, CONN.

Boyd¹ in 1931 stated that "a rare form of acute bacterial endocarditis is that produced by the gonococcus." Though at first it would appear that this form of endocarditis is not so rare, judging by the number of cases reported in recent years, when one contrasts the incidence of gonococcic endocarditis to the prevalence of gonococcic infection in the male and female, it may truly be said that cardiac involvement by the gonococcus is a rare occurrence. Hoffman and Taggart,² in reviewing the literature since 1922, report that they could find only eight authentic cases of endocarditis caused by the gonococcus and add their own case. Since we can prove the source of the infection in our cases together with the finding of gonococci in smears from the vegetations taken from the aortic valve, plus a strongly positive gonococcus complement fixation test in one of the cases, we feel privileged to add our cases to those in the literature. The unusual features in our cases are that death occurred only five days after the first evidence of cardiac involvement and that bilateral hydrothorax was found in each case.

REPORT OF CASES

CASE 1—C. K., a man, aged 42, admitted to the surgical service, March 11, 1931, complained of swelling and pain in the left hand of one week's duration. Three weeks before the patient had fallen, injuring the left hand, but the hand did not trouble him until two weeks later, when it became painful and swollen. The patient was well developed and well nourished, the only positive finding being that the left hand was tensely swollen and reddened from the wrist down, with extreme pain on movement at the wrist. It was thought at this time that the patient had an infection of the hand, and it was incised between the metacarpal bones and drained. After three or four days there was a small amount of pus draining, but the wound showed no signs of healing. At the end of one week the signs of acute inflammation had subsided and the hand showed marked improvement. The temperature on admission was 101 F and for the next two weeks varied between 98 and 100 F, reaching 103 once on the tenth day after admission. The pulse during this time ranged between 70 and 100, and the respiration rate was 20 per minute.

March 25, two weeks after admission, the patient suddenly had a severe chill, lasting twenty minutes, and the temperature shot up to 104 F, and the pulse to 120. Three days later, March 28, the patient complained of pain in the right shoulder, with limitation of motion. A blood count on this day showed 13,600 white blood cells and 65 per cent polymorphonuclears, and a blood culture was taken. Salicylates were given up to the saturation point, but there was no effect on the painful shoulder. Beginning March 25, the temperature course became septic in type, with daily peaks of 102 and 104 F in the afternoon. The patient gradually became worse, the pulse fluctuating with the temperature between 80 and 120. April 1 the patient began to cough, expectorating a yellowish sputum, he became very restless and a difficulty in breathing developed. Dulness with diminished fremitus and crackling rales over both bases posteriorly was noted.

¹ Boyd, William. The Pathology of Internal Diseases. Philadelphia: Lea & Febiger, 1931, p. 59.
² Hoffman and Taggart. Gonococcus Endocarditis. *Ann Int Med* 5: 1397-1403 (May) 1932.

April 6, for the first time, there was heard a double murmur over the entire precordium, loudest over Erb's point. At this time it was also discovered that the patient had had a gonorrheal epididymitis with urethral discharge three months previously. Two days later another blood culture was taken. During the next few days the patient rapidly became more toxic, having daily chills and profuse perspiration with increasing dyspnea. The pulse became more feeble and two days before death the respiration increased to from 40 to 50 per minute. The next day Cheyne-Stokes respiration appeared, the patient became cyanotic, and he died, April 11.

Both blood cultures were reported as showing no growth at the end of five days. The blood count, April 7, showed 8,000 white blood cells, with 87 per cent polymorphonuclears, reported as very toxic.

Autopsy was performed by Dr. Peters. There were no petechiae in the skin and no subconjunctival hemorrhages. When the abdomen was opened there was about 50 cc. of clear serous fluid in the peritoneal cavity but no evidence of peritonitis. When the chest plate was removed about 600 cc of slightly blood-tinged fluid was found in each pleural cavity. There were no adhesions in the pleural cavities and the lung was crepitant except for areas in the lower lobe, which on section showed passive congestion. The heart was moderately enlarged, weighing 500 Gm. The right auricle was markedly dilated and filled with a postmortem clot. The first part of the aorta showed no abnormality, but the cusps of the aortic valve presented a fairly large recent ulceration in the central portion of the left posterior cusp, with the edges of the ulcerated area covered by soft vegetations.

A smear taken from the vegetations on the valve showed the presence of numerous biscuit-shaped gram-negative diplococci resembling gonococci. The spleen was slightly enlarged, weighing 250 Gm, and slightly softer in consistency.

CASE 2.—M. Q., a woman aged 39, admitted to the Bridgeport Hospital, Oct. 26, 1933, in the surgical service of Dr. H. B. Lambert, complained of vaginal pain of several years' duration and of low abdominal pain for the past few months. There was no pain on urination nor intermenstrual discharge. The menses were normal and regular. The patient had been separated from her husband for several years but continued to consort with men. On examination, there was elicited moderate pain and tenderness over both lower quadrants of the abdomen. Pelvic examination showed a retroverted uterus and ulcerated cervix. In the right fornix was felt a large knobby, tender mass suggestive of a pelvic abscess. The patient was in the hospital fourteen days. On admission the temperature was 103, which dropped to 98 on the third day and remained afebrile. The vaginal discharge was very slight and smear showed many pus cells with a few gram-positive cocci and bacilli. The blood Wassermann and the Kahn test were negative. The ulcerated cervix was treated with electrocoagulation and the patient felt improved and was discharged, November 9.

November 23 the patient was readmitted to the medical service of Dr. F. W. Pyle, complaining of generalized aches over the body and pain in the right wrist. She stated that one week after her discharge from the hospital she began to have chills and at one time had a fever of 105 F. A few days later she had another chill and fever. About the time of the first chill there was some burning on urination. November 20 a severe pain developed in the right wrist, which became swollen and reddened, and two days later the right knee became painful and swollen. The patient was acutely ill, with a temperature of 102 F. The lungs were clear and the heart was normal, no murmurs were heard. There was no vaginal discharge and no tenderness in the vaginal fornices. The right wrist and right knee were swollen, red, hot and very tender to palpation. In the course of the illness on the fifth day the temperature dropped to 98.8 and remained normal. The swelling of right knee subsided in a few days, so that all pain disappeared. One week after the day of admission the acute inflammation of the right wrist subsided and physical therapy was instituted. At the end of the second week the right wrist had improved greatly, with all pain gone and a great deal of motion possible. During this admission the white blood count was 15,700, with 81 per cent polymorphonuclears, the red blood count was 4,460,000 and the hemoglobin 88 per cent by

the Sahli method. The patient was discharged as improved, December 7.

It was at about this time that we discovered that a friend of our patient was being treated by a local physician for a gonorrheal urethritis. The man insisted that he had contracted the infection from the patient in the interval between her admissions to the hospital. After discharge from the hospital the patient was apparently well until December 12, when she had a severe chill lasting one hour, followed by a high fever.

December 13 the patient was readmitted with the complaints of chills and fever. Physical examination at this time showed the patient to be acutely ill, with a temperature of 101 and pulse of 120. The right wrist had improved and showed no evidence of inflammation. There were no positive manifestations, as the lungs were clear and no murmurs were heard on careful examination of the heart. The blood count, December 14, showed 13,550 white blood cells, with 72 per cent polymorphonuclears and a hemoglobin of 80 per cent. In the next few days the patient complained of frequent headaches and chilly sensations, with the temperature ranging between 101 and 104 F. Five days after admission the patient began to

Aortic valve showing typical vegetations of acute gonococcic endocarditis, with ulceration of the leaflet.

cough, and some dullness with diminished breath sounds were found over the left lower lobe posteriorly. A blood culture, was taken, December 18, but was reported negative at the end of five days. The blood count, December 18 showed 10,400 white blood cells, with 83 per cent polymorphonuclears, and 4,200,000 red blood cells, with 75 per cent hemoglobin (Sahli method). During the next two and one-half weeks the patient showed no signs of improvement, the temperature remaining elevated between 102 and 104 F, the pulse between 90 and 120 and the respirations from 20 to 30 per minute. The patient was gradually becoming more and more toxic. Jan. 2, 1934 the blood count showed 23,700 white blood cells with 90 per cent polymorphonuclears. The respiration rate ranged between 40 and 50, the pulse was 120 and the temperature fluctuated between 102 and 104 F. This same day, for the first time, Dr. C. W. Gardner heard a distinct diastolic murmur, loudest in the left fourth interspace. Another blood culture was taken, January 4, which did not show any growth at the end of five days. January 5, a gallop rhythm developed, there was tubular breathing at both bases and abdominal distention. Several petechiae were noted in the skin of the chest. The patient became increasingly more dyspneic, the pulse became feeble and rapid, 132 per minute, the patient lapsed into unconsciousness and died January 7.

Other laboratory data included a sedimentation rate of 25 minutes, the urine on repeated examinations showed a specific gravity of 1.009 to 1.016, faint traces of albumin and many white blood cells and a few red blood cells. Blood taken, January 4, for the complement fixation test was returned January 8 strongly positive for gonococci.

An autopsy was performed one hour after death by Dr. Horn. The body was 5 feet 6 inches (167 cm) tall and weighed 125 pounds (56.7 Kg). The conjunctivae were clear, the abdomen was slightly distended and tense, and the nail beds were cyanotic. There were two petechiae in the skin, one over the right upper portion of the chest and one over the left lower part of the abdomen. When the abdomen was opened there was from 50 to 100 cc of amber fluid. When the chest plate was removed, about 500 cc of turbid amber fluid was found in each pleural cavity and the lungs appeared to be collapsed with a few fresh adhesions between the lungs and the chest wall. When removed, the left lung was partially collapsed, the upper lobe gray and crepitant, the lower lobe purplish and fleshy. On section, the cut surface of the lower lobe was slightly moist but there was no exudate visible nor expressed. The appearance was that of compression atelectasis. The lower lobe of the right lung showed a similar appearance.

The pericardium, when opened, contained about 30 cc of clear amber fluid. The right auricle was moderately dilated. The heart was normal in size, weighing 325 Gm and was moderately soft, and the epicardial surface over the root of the pulmonary artery presented a bloodshot appearance. The positive changes were restricted to the aortic valve which are shown in the accompanying illustration. Involving the left posterior cusp of the aortic valve were seen several large friable vegetations. Some of the vegetations were smooth, thick yellow masses dangling from the valve leaflet while most of the vegetations both on the leaflet and within the sinus of Valsalva were coarsely verrucous and cauliflower in appearance. The valve leaflet itself presented an irregular ulcerated hole about 1 cm in diameter, the edges being covered by the vegetations. The left coronary artery had its origin about 1.5 cm above the upper level of the valve leaflet, while the right coronary artery opening was in its normal position.

The spleen was somewhat enlarged, weighing 215 Gm, bright red and moderately soft. The liver was enlarged, weighing 2,050 Gm.

In the pelvis was found a right pyosalpinx. The right fallopian tube was adherent to the right ovary and both were bound down in the culdesac.

Some of the verrucous vegetations from the aortic valve were crushed and the smear stained, revealing many pus cells and gram-negative extracellular and intracellular diplococci, evidently gonococci.

COMMENT

The reported cases present several points in common. A chronic gonococcal infection was present in both. The man had had gonorrhea and a gonococcal epididymitis three months previously, the woman had had a pelvic infection with a pyosalpinx, most probably gonococcal in origin. In both, arthritic manifestations developed and the joint primarily involved in each case was the wrist. In each the process became malignant in that death occurred only five days after the cardiac involvement. In both, the aortic valve was involved, the appearance of the vegetations was similar, being bulky and ulcerative, and in each case we obtained positive smears directly from the vegetations showing gonococci.

In view of these conditions we feel that these cases may be regarded as proved cases of gonococcal endocarditis. In support of this view, we have the strongly positive complement fixation test in case 2. That the infection, once involving the heart, was highly malignant is evidenced by the fact that, only five days after the first physical finding of cardiac involvement, death occurred and by the gross appearance of the aortic valve, showing the extensive ulcerations of the valve leaflets.

Another unusual finding in both our cases was the presence of bilateral hydrothorax.

SUMMARY

1 In two proved cases of malignant ulcerative gonococcal endocarditis there was a positive history of gonococcal infection.

2 Smears from valve vegetations showed gram-negative, biscuit-shaped, intracellular diplococci, evidently gonococci.

3 In one case the positive manifestations were strengthened by a positive complement fixation test.

4 Both cases were rapidly fatal in five days after the first evidence of an endocarditis.

5 Bilateral hydrothorax was present in both cases.

RIGHT AXILLARY EMBOLECTOMY

RECOVERY WITH RECURRENCE ONE MONTH LATER

MAY DANZIS, MD

AND

CLEMENT H. GOLDEN, MD

NEWARK, N. J.

The operation of arterial embolectomy and its results have aroused a great deal of interest among surgeons during the last decade. The number of cases reported is continuously increasing. Recently, several reports have appeared in the European and American medical literature in which the accumulated collective experience of a large series of cases reported by a diversified group of surgeons was tabulated and an attempt was made to draw some definite conclusions as to the prognosis and mode of treatment from the end results. Many successful arterial embolectomies, limited to one or two cases, have also frequently appeared in the literature, but the ultimate end results weeks or months after the operation are not stated. In some so-called successful cases in which the circulation has been completely restored, which are listed as cures, secondary emboli may have developed, followed by gangrene or death. It is fair to assume that an equal or a greater number of cases in which the operation was unsuccessful were not reported, since often successes are more likely to be reported than failures. The widespread interest in the subject prompts us to report another case of arterial embolectomy, which has many points of interest from a diagnostic and prognostic standpoint.

REPORT OF CASE

CASE 1—E. S., a widowed housewife aged 62, a Russian, was seen by one of us (C. H. G.) in a typical attack of coronary thrombosis, Oct. 14, 1931. The patient suffered from dyspnea and severe precordial pain. Her pulse was barely perceptible. Morphine was administered and an ice bag applied to the precordium, and the following day she was admitted to the Newark Beth Israel Hospital suffering with auricular fibrillation and marked cardiac decompensation. Under prolonged rest and medication her condition improved. She was discharged from the hospital and transferred to a convalescent home.

Oct. 20, 1932, she was again admitted to the hospital markedly decompensated and also suffering with diabetes mellitus. The blood sugar was 333 mg and glycosuria 8 per cent. Under the proper diet and insulin she became sugar free and was discharged from the hospital one month later.

From the Surgical Service, Newark Beth Israel Hospital.

During the winter of the same year the patient was sent to the Newark City Hospital because of a marked right-heart failure. During her stay at the hospital psychotic symptoms of a paranoid nature developed, which disappeared after several weeks' treatment.

Roentgenologic examination of the heart at that time showed it to be enlarged and of the mitral type. There was also hilar and pulmonary congestion. During the early part of November 1933 the patient was admitted to the Lincoln Private Hospital with evidence of left ventricular failure and auricular fibrillation. Compensation was soon restored by maintenance doses of digitalis and small doses of morphine. She complained of occasional vague and irregular pain in both lower extremities. There was no evidence of sclerosis in the peripheral and retinal arteries.

November 19, at 12:30 a. m., she was seized with an agonizing pain in the right shoulder and upper arm. It was knifelike in character and did not radiate. The forearm and hand became immediately cold and anesthetic. When examined by one of us at 1:45, she was in shock. Her face was ashen, she was bathed in sweat, and the pulse was irregular, with a rate of 140. The whole right upper extremity was cold and had the appearance similar to a neonatal asphyxia pallida. There was complete absence of brachial or radial pulsation in the right arm and forearm. There was a marked pulsation at the upper third of the axillary artery but none below that point, and there was forceful pulsation in the subclavian artery. Hypodermic injection of morphine, given immediately, failed to relieve the pain. The diagnosis of axillary arterial embolus was made, which was verified in consultation with Dr. Max Danzis, and immediate operation was advised.

Under local block anesthesia, operation was begun at 3:45 and completed at 4:30. An incision 3 inches (7.6 cm.) in length was made directly over the course of the axillary and brachial arteries. The axillary vessel was identified and separated from the brachial nerves. A tape, dipped in saline solution, was carried around the upper portion of the brachial artery. Another tape was similarly carried around the axillary artery, proximal to the obstructed segment. The upper part of the brachial artery was gently compressed, its contents were milked upward and the artery was then constricted by tying the tape with a slip knot. The clot could be distinctly felt within the lowermost portion of the axillary and could be easily moved in both directions. The proximal tape was then also tied with a slip knot and a longitudinal incision was made in the arterial wall, between the two tapes about two thirds inch in length. Three small thrombi, each about 1 cm. in length, of a firm consistency, yellowish red in appearance, were removed. The knot in the upper tape was then released and blood spurted freely and forcibly from the axillary artery. No other clots were expelled in that blood stream. The tape was then retied and the incision in the artery was closed by five No. 0 silk sutures dipped in petrolatum. Both the upper and lower tapes were removed, blood flowed freely through the artery, and pulsation of the brachial artery was immediately visible and palpable. The cessation of pain and the return of the circulation took place with a dramatic suddenness. The pallor of the hand disappeared and it resumed a normal appearance. In spite of the apparent circulatory restoration to the entire forearm and hand pulsation in the radial could not be felt. This would presuppose a return of circulation through the anastomotic branches around the elbow joint. The soft parts were closed with interrupted silkworm-gut suture and a dry dressing was applied.

The patient was returned to bed in good condition but with an irregular pulse. One-fourth grain (0.016 Gm.) of morphine was given hypodermically to combat shock and restlessness. The arm was kept in a moderately abducted position, on a soft pillow, and an anterior splint, well padded, was applied so as to prevent unnecessary motion for the first forty-eight hours. The subsequent postoperative course was uneventful. Sutures were removed on the tenth day. The circulation was well maintained. There was no disturbance of sensation or motion. The pulse was 96 but irregular. The cardiac compensation was well maintained while she was at rest. There was no difference in the appearance of the two upper extremities.

The patient was transferred to the Newark Beth Israel Hospital, November 29, with a diagnosis of cardiovascular disease. Progress notes, December 1, show "general condition of patient good, embolectomy incision well healed, heart beats very irregular, suggesting advanced conduction defect and myocardial damage." December 7 the condition was fair and the pulse was weak and irregular, there was no dyspnea and no pain. December 14 and 17 there were no complaints, the condition was good.

During her stay at the hospital the circulation of the arm and forearm was good, the brachial pulsation was present all along the course of the artery, but the radial pulse could not be felt during the first three weeks following operation. After that, irregular radial pulsation was present. The patient was able to use her arm freely. There was no numbness or visible circulatory disturbance.

December 18, when the patient was lying comfortably in bed, she suddenly complained of a faint feeling, followed by pain in the right arm, forearm and hand. The circulation of the hand was immediately disturbed, and the same subjective and objective symptoms, similar to those of the first onset, were present. The pain, however, was not as severe at this time as in the first attack. It seemed not to have been as sudden in its onset. Pulsation in the brachial and axillary was again absent. There was distinct pulsation of the axillary artery but none below. The diagnosis of recurrent embolus of the axillary artery, or the beginning of the brachial artery, was made. Reoperation was advised.

Clots removed from right axillary artery at time of first operation Nov. 19, 1933. These were reddish yellow and nonfriable, approximately 1 cm. in length. Sections showed formed thrombi.

Under local anesthesia, the upper portion of the brachial and axillary arteries were exposed. We encountered considerable difficulty in isolating the axillary artery on account of very thick and firmly adherent scar tissue around that vessel, as a result of the previous operation. Strands of silk, which were used in the former arteriotomy closure, were still visible in the scar. Pulsation was visible above the scar and none below. After the segment of obstructed vessel was liberated from its bed of scar tissue, distinct diminution in the caliber of the vessel was noticeable. On palpation, a thrombus was felt at that point. An incision was made and two small thrombi were evacuated and the constriction was then released. This was followed by a spurt of blood and the expulsion of another small thrombus. The blood was allowed to spurt intermittently for several seconds. The tapes surrounding the vessel were then tied by a slip knot and the incision was closed by very fine silk suture dipped in petrolatum. There was no restoration of circulation in the brachial artery after the closure. The forearm and hand remained blanched. Owing to the marked constriction of the vessel, it was deemed inadvisable to reopen the sutures to search for any new clots, because repeated incision and manipulation is most likely to cause further narrowing of the lumen. The general condition of the patient at this time also became very poor, and the operation was therefore terminated by merely closing the incision with through and through silkworm gut sutures, in the hope that the circulation of the forearm and hand might be reestablished through the collateral vessels.

The patient was returned to bed in a state of shock. The arm was kept in the abducted position, heat applied and general stimulation administered. The following day the symptoms of circulatory disturbance became aggravated. Within the next three days definite signs of dry gangrene appeared at the tip of the fingers and hand. No pulsation could be felt at the brachial artery. The general condition of the patient became very poor and many dark blotches appeared on the forearm, showing the progressive extension of the gangrene. Amputation was considered, but the patient's general condition contraindicated any surgical intervention at that stage. The patient died, Jan. 5, 1934, seventeen days after the operation, from cardiovascular disease and toxic absorption from the gangrenous limb.

COMMENT

The vascular constriction found at the operation caused some speculation in the mind of one of us as to the exact cause of the circulatory obstruction. Was it due to the lodgment of a new embolus? Or did the small thrombi, which we removed from the vessel, form slowly within the lumen of the artery, as a result of the constriction at that point? The latter assumption is supported by the clinical history, that the onset of symptoms was not as sudden and the pain not so severe as in the first attack. This may indicate that the obstruction could have been gradual and the symptoms became most pronounced only when the size of the thrombus at the constricted portion of the artery became sufficiently large to cause complete occlusion of the lumen at that point. On the other hand, the fact that during the four weeks that intervened between the first and the second operation the patient experienced no symptoms suggestive of local circulatory disturbance in the arm or forearm and that the pulsation of the brachial artery was well maintained from the time that the clot was removed, and the fact that radial pulsation also returned at about the third week indicate that there was no interference with the arterial flow of blood as a result of thrombus formation. The sudden faint feeling experienced by the patient immediately preceding the onset of local symptoms, the sudden marked change in the appearance of the hand and forearm, and the sharp pain, although not as acute as in the preceding stage, would also indicate a sudden circulatory obstruction, most likely due to another embolus.

The importance of early diagnosis and prompt surgical intervention in cases of arterial obstruction due to emboli has been stressed by many writers. It has definitely been shown that the danger of circulatory obstruction by an embolus is greater than that caused by ligature, because, in the former, thrombus formation rapidly takes place not only in the parent vessel but also in the arterial branches that are given off at the embolic site, causing complete occlusion of the main trunk and its branches, whereas in obstruction due to a ligature, the branches that are given off below the point of ligation are not obliterated, and the circulation of the limb may therefore be maintained through these collateral anastomotic branches.

Experimental ligation of the subclavian, axillary and brachial arteries gave an incidence of gangrene varying between 15 per cent in the axillary and 48 per cent in the brachial, whereas the incidence of gangrene as a result of circulatory obstruction due to emboli, based on a study of twenty-nine cases, proved to be 30 per cent. In most of these cases operation was performed soon after the onset of the disease.¹

It was definitely shown that the degree of infiltration of the intima of the blood vessels and the size of the thrombus within the lumen of the artery are in direct proportion to the length of time allowed to elapse between the onset of the disease and the operation. If the embolus is allowed to remain within the vessel for a considerable length of time, it will cause ulceration and necrosis of both the intima and the media at the point of obstruction. The thrombus formation will then extend from the principal vessel at the point of obstruction to its collateral branches, causing a complete occlusion of the arterial canal and its branches.

The importance of early operation was definitely shown in an analysis of the postoperative end results of a large series of cases. Of those in which operation was done within from one to four hours there was a complete circulatory restoration in 62 per cent of the cases. Of those in which operation was performed within from four to eight hours there was only 50 per cent circulatory restoration. The percentage of circulatory restoration decreased in direct proportion to the operative time. There is no authentic case of complete circulatory restoration in the vessels of the lower extremities in which operation was done forty-eight hours after the onset of the disease. There are several reports in the literature of circulatory restoration in the vessels of the upper extremity in which the operation was performed forty-eight hours after the onset of the disease, but in these cases the circulation was probably restored through the collateral branches.

In a study of the end results of ten cases of embolectomies performed on the vessels of the upper extremity in which the circulation was restored, no radial or brachial pulsation could be felt nor could a blood pressure reading be obtained weeks and months after the operation. This would definitely indicate that the collateral branches play a most important part in the circulatory restoration of the vessels of the upper extremity.¹

One may ask. If the collateral branches play such an important part in circulatory restoration, particularly in the vessels of the upper extremity, why resort to embolectomies, particularly in debilitated patients? The answer is obvious. As was stated before, if the embolus will be allowed to remain at its point of lodgment, particularly if it is near the bifurcation of a vessel or at a point where the collateral branches are given off, the thrombus formation will extend into these collateral branches and deprive the patient of whatever chances he may have of circulatory restoration through these anastomotic branches.

The incidence of emboli is less frequent in the upper than in the lower extremities. In a group of 129 cases¹ there were 29 of the upper extremity and 100 of the lower extremity. The cause of this marked difference is not definitely known. The relative frequency between the lodgment of an embolus in the right or the left upper extremity has not been estimated with any degree of accuracy. The experience of some writers shows that emboli are apt to lodge more frequently in the left arm than in the right. The cause of this condition is attributed to the difference in origin of the subclavian arteries on either side. When an embolus leaves the left side of the heart and is propelled by the blood stream into the arch of the aorta, it may enter into the lumen of one of the three large vessels originating from the arch. If it enters the innominate artery and is not arrested at its bifurcation into its two branches

¹ Danzis, Max. Arterial Embolectomy. *Ann. Surg.* 98: 249 (Aug.) 422 (Sept.) 1933.

(right subclavian and right common carotoid), it may enter either one of these two vessels. But if the embolus propelled by the force of the blood stream passes by the first two openings and enters the left subclavian, it can be propelled only into the axillary. On the other hand, one may take the opposite view that, since the direction of the arch of the aorta is from right to left, the innominate artery arising from the right side of the arch is logically the first vessel that an embolus would encounter in its course after being driven off by the blood stream from the left ventricle and should most likely find entrance into the lumen of that vessel first, and therefore the incidence of right-sided axillary emboli should be greater than or at least equal to that of the left side. However there is no definite physiologic proof adduced at present to substantiate either one of these two assumptions. Out of twenty-nine cases of embolus of the upper extremity¹ reviewed in the literature, including the cases reported by one of us and also the case we are reporting at present, the right side seems to predominate. In Key's² personal experience the left side predominates.

The interesting points in this case are (a) Complete circulatory restoration in the right arm following axillary embolectomy about two and one-half hours after onset. Evidently the circulation was well maintained for a period of one month through the regular arterial channels, as evidenced by the immediate restoration of pulsation in the brachial artery and the restoration of radial pulsation later on. (b) A recurrence of an embolus in the same vessel and almost at the same site, which is rather unusual. Many cases of recurrent emboli, subsequent to embolectomies, are reported in which the emboli lodged in vessels other than those on which the embolectomy was performed. Cases are also reported in which there were concomitant emboli lodged in different parts of the body at the same time. The incidence of other embolic deposits preceding, associated with or following the operation of embolectomy were shown to be very frequent in the group of 129 cases reported in the literature. A repeated lodgment of an embolus, at the same site, is rather unusual.

The advisability of operative intervention, under such circumstances, may be questioned, particularly in an artery of moderate size. The periarterial scar formation following the first operation makes the localization and isolation of the segment of the vessel in which the embolus has lodged very difficult. The already narrowed vascular lumen at the site of the previous arteriotomy incision may be further reduced in size by the second operation, causing a complete blockage of the arterial circulation at that point. Since it has been clinically proved that circulatory restoration has been definitely reestablished in several cases of axillary and brachial arterial emboli in which no operation was performed, the possibility of circulatory restoration—if not complete, at least partial—may be expected, and nonoperative expectant treatment may be given consideration.

We realize that it is impossible to draw definite conclusions as to the choice of method of treatment from such a limited experience. Further study of the operative end results of a larger group of similar cases is necessary before a more positive method of treatment can be arrived at.

HUMAN THALLOTOXICOSIS

JAMES C MUNCH, PH D

GLEN OLDEN, PA

In connection with an outbreak of thallium poisoning in California¹ the question arose regarding the frequency of human thallium poisoning. General reviews of the pharmacology of thallium,² as well as a number of scattered articles, have reported only single or a few cases. In the preparation of this compilation, efforts have been made to consult original articles pub-

POISONING FROM INDUSTRIAL PRACTICE

Following the original reports of Crookes in 1861 and of Lamy in 1863, thallium has been obtained from various ores, and from the flue dust of plants roasting pyrites or raw sulphur in manufacturing sulphuric acid.^{2b} Prussian plants handling thallium answered questionnaires regarding industrial poisonings sent by Buschke³ at the request of the minister of health. In addition, reports have been made⁴ covering accidents following industrial exposure (table 1). Five German chemical manufacturers handling thallium salts and compounds on a commercial scale reported that no evidence of thallotoxicosis had been observed among their employees. Twelve persons employed in three other plants have developed thallium poisoning, nine of these recovered when the exposure was terminated,

dysentery caused alopecia. Clinical studies⁵ led to the use of thallium compounds (usually thallous acetate) for the production of cranial alopecia, as a preliminary step in the treatment of favus, trichophyton and microsporon infections of the scalp. A definite quantity of thallous acetate (most frequently 8 mg per kilogram of nude weight) is administered in a single dose to a healthy prepubescent child. An interval of from two to six months (usually three months) has been recommended before readministration of thallium compounds.

The dose of thallium acetate has varied from 4 to 10 mg per kilogram. Results reported in the literature have been consolidated in table 2. It is probable that a dose of 8 mg per kilogram was used in those instances in which the dose was not stated. Reports

two showed chronic albuminuria, and one employee lost his sight.

Two American dealers in thallium report no evidence of thallotoxicosis among their personnel. No report of death from thallium poisoning following industrial contact has been found.

POISONING FROM CLINICAL USES

Internal Use of Thallium Acetate as Depilatory—Apparently the first connection between the internal administration of thallium and the loss of cranial hair was made by Sabouraud in 1897. Pills containing thallium acetate administered for the treatment of

on 8,006 cases were found. Intoxications were produced in 447, or slightly over 5.5 per cent. Eight deaths are reported. Following the administration of 8 mg per kilogram, six deaths have been recorded: (a) Two boys, aged 5 and 7 years, developed myeloencephalitis and pneumonia and died on the sixth and tenth days; (b) three boys, aged 7, 10 and 10 years,

of a boy, aged 4 in status thymicolymphaticus twenty-six hours after administration of 875 mg per kilogram. In discussing this paper, Lapin¹⁰ stated that a girl, aged 8, vomited many ascarides and died following the administration of thallium acetate.

Ingram¹¹ concluded that there is no evidence of danger following the clinical use of the proper dose of

¹⁰ Lapin in discussion on paper by Globus.
¹¹ Ingram J T. Thallium Acetate in the Treatment of Ringworm of the Scalp. Brit M J 1 810 (Jan 2) 1932.

thallium acetate as a depilatory Percival¹² was unable to find any evidence of impairment in the growth of seventy-six children following its use as a depilatory.

Thallium poisoning has followed clinical administration under what authors have suggested to be "improper clinical conditions" (table 3). Merkel¹³ reports the death of three undernourished boys, aged 10, 11 and 12 years, following the administration of from 55 to 6 mg per kilogram, not as a single dose but in divided doses over five, four and seven days. Poisoning followed 8 mg per kilogram given to a boy, aged 13, in two doses,¹⁴ also three children given a "full epilating dose" two or three times at weekly intervals.¹⁵ A Negro boy, aged 7, died on the twenty-

after the fifth daily dose of 125 mg per kilogram. Of thirty-three patients affected, twenty-two died.

External Application of Thallium Ointments as Depilatories—Sabouraud⁵ reported the possibility of using an ointment containing not over 1 per cent of thallium acetate in the treatment of hypertrichosis. Under medical supervision a quantity not exceeding 2 grains (0.13 Gm) of wheat is applied. The danger of using thallium ointments as depilatories has been pointed out by a number of dermatologists.¹⁶ Detailed records of injury following the use of such ointments are included in table 4. Abnormal conditions developed at different rates, possibly because of differences in the concentration of thallium and the rate of absorption. The duration of the injuries varied similarly.

A number of cases of thallium poisoning have been reported²⁰ during the last two years, following the application of a thallium ointment, "Koremilu Cream". Analysis of different lots of this material have been reported, indicating that the thallium acetate content falls between 3 and 8 per cent. Case histories of fifty one women poisoned by this product are given in table 4.²¹

The external application of ointments containing thallium compounds produced the same symptoms as the oral administration of thallium acetate. No claim is made that this list is complete, most probably it is not. The fifty-nine patients listed were those treated by physicians and recognized as suffering from thallium poisoning, the number of cases of poisoning not diagnosed, patients exhibiting mild thallotoxicosis who failed to apply for aid, and those in whom definite evidence of thallium poisoning did not develop can hardly be estimated. No death has been found directly attributable to thallium poisoning following the use of thallium ointments.

Miscellaneous Medicinal Exposures—A number of cases of poisoning have been collected in which thallium salts were taken internally (table 5). A total of 153 cases are considered, excluding an indeterminate number of cancer cases reported by Copeman.²² One boy died following the ingestion of 2.5 Gm of thallium solution intended for incorporation in a vehicle for external application to the scalp.²³

Recapitulating, 692 persons have been poisoned in connection with medicinal uses of thallium compounds, in thirty-one cases, death resulted.

POISONING FROM TOXICOLOGIC EXPOSURE

Homicidal, suicidal and inadvertent exposure to thallium products in foods have been reported. Two of a family of seven died following the consumption of food containing thallium and zinc.²⁴ Six unsuccessful attempts at suicide have been reported, in which from one-half to one and one-half tubes of "Zello" paste were ingested. Since this product contains about 2 per cent of thallium sulphate, this would represent a probable dosage of between 300 and 900 mg of thallium sulphate per person. Two cases of murder have been found. 1. A mother murdered her child by administering an unknown amount.²⁵ 2. A wife murdered her husband by feeding him between two and one-half and three tubes in his food.²⁶ "Thalgrain" containing 1 per cent of thallous sulphate was ground and the flour used in a preparation of tortillas in California in 1932

of high toxicity, and is without taste, smell, or other warning property. It should not be recommended to the public as a rodent poison. Where the use of thallium is found necessary for the control of highly resistant species of rodents, it should be entrusted only to persons who understand its dangerous qualities and who will exercise appropriate care in handling it. By using proper precautions, no case of thallium poisoning has ever been observed among the personnel of those official agencies preparing thallium baits for rodent control.

A definite field has developed for thallium pastes and syrups in the control of certain species of ants, particularly in the Southwest. Correspondence with a number of manufacturers and state entomologists reveals that three cases of accidental human poisoning have been reported,²⁷ with no deaths.

Total 53 affected 10 deaths						

These thalliferous tortillas were consumed by at least thirty-one Mexicans. Symptoms developed in twenty, and six died from primary thallotoxicosis within sixteen days.¹ A total of fifty-three persons have been poisoned by thallium compounds under this classification, and ten have died.

POISONING FROM RODENTICIDAL AND ENTOMOLOGIC USES

The use of thallium as a rodent poison apparently originated with "Zello" about 1920. Our investigations²⁸ led to the use of thallium compounds (usually thallium sulphate) for the control of rodents, under restricted conditions. "Thallium is a cumulative poison

1. Thallium compounds have been used by commercial agencies engaged in the extermination of rodents "varmints" and pests. Only one case of human poisoning has been reported in this country following such use. Sandwiches of bread and peanut butter containing crude thallium sulphate were exposed by an extermination company. Children placed part of a sandwich in the carriage of a 19 months old child, who ate it. Death occurred on the eleventh day, after the appearance of typical symptoms of thallium poisoning²⁸ (table 7).

2. Poisoning following thallium pastes has been reported in foreign literature. A 2 1/2 year old child died twenty-nine hours after consuming an unknown quantity of bread coated with thallium paste exposed

as a rat poison, a 4½ year old child also ate some of the material but survived²⁹

3 Following the consumption of 'Zelio' grain, which contains approximately 2 per cent of thallium sulphate, four persons have been affected, and two deaths resulted³⁰

Five children have been poisoned following accidental consumption of thalgrain but completely recovered³¹ In another instance,³² a family of six consumed a mush containing thalgrain as one constituent, and all were poisoned the five adults recovered but the 15 months old baby died with atypical symptoms

Rodenticidal and entomologic baits have poisoned twenty-one human beings, and five died

SUMMARY

1 An extensive search of the literature prior to January 1934 has been made to learn the extent of human poisoning from thallium compounds and the number of deaths resulting therefrom

2 Following industrial exposure twelve persons have been poisoned, but none died

3 Following clinical use, 692 persons have been affected and thirty-one deaths resulted

4 Toxicologic literature records fifty-three human beings poisoned by thallium compounds, with ten deaths

5 Following the rodenticidal and entomologic use, twenty-one human beings have been poisoned and five died

6 Reports have been found on 778 human beings poisoned with thallium compounds, forty-six (6 per cent) died of thallotoxicosis

Clinical Notes, Suggestions and New Instruments

DESENSITIZATION TO INSULIN ALLERGY

LEONA M BAYER M.D. SAN FRANCISCO

This is the report of a case in which increasingly severe constitutional reactions to insulin were shown, which largely subsided after an intensive course of desensitization. There being a growing recognition of the occurrence of insulin allergy, and the constitutional type of reaction being more difficult to control than the local wheal, it was thought that an account might be of practical interest. The literature on the subject is by this time quite extensive, although there appear to be only some ten cases of generalized reaction on record. Three articles, in English,¹ French² and German,³ respectively, cover the subject to date and among them list a large bibliography.

REPORT OF CASE

Mrs H S, aged 48, came of a family in which diabetes developed in the mother and each of three siblings between the ages of 35 and 54. Her own involvement manifested itself at the age of 40 by polyuria and polydipsia, but except for brief dietary control at the age of 42 necessitated by a siege of pruritus vulvae, the disease was ignored until the age of 45, when a moderately severe pyorrhea brought the patient under dental and medical observation.

At that time, April 1930, the patient weighed 176 pounds (80 Kg), being about 40 pounds (18 Kg) overweight. The blood pressure was 150 systolic, 80 diastolic. There were pyorrhea and small cryptic tonsils. Laboratory work showed three plus glycosuria in all samples of urine, no diacetic acid, and a blood sugar of 198 mg per hundred cubic centimeters. The basal metabolic rate was -7 per cent. Otherwise the examination was normal.

By November 1933 the weight was 165 pounds (75 Kg) net, and the pyorrhea was cured, otherwise the patient's physical status remained the same. The diabetes had grown steadily more severe, but she had never shown an acidosis.

The glycosuria was at first easily controlled by a diet of approximately carbohydrates 40 Gm, protein 50 Gm and fat 100 Gm, totaling 1,260 calories, which was adhered to very indifferently but which could be counted on to clear up within forty eight hours any sugar that appeared after dietary sprees. This type of high fat diet was resorted to after higher carbohydrate values failed to clear up the sugar and in the face of persistent aversion to the use of insulin.

The first necessity for insulin came when, in March 1932, there was a rather severe paronychia and cellular infection of one thumb which resulted at first in the loss of the nail, although finally a completely normal finger was restored. A severe glycosuria failed to clear up appreciably on strict diet for twenty-four hours, and it was desirable to control the diabetes immediately. At this time, therefore, 5 units of insulin Mulford (20 units) was taken once or twice a day for a period of ten days, as dictated by urine tests. There were no allergic manifestations. After stopping insulin, the patient continued usually sugar free for some months on the old diet.

In April 1933 she reappeared with a general feeling of malaise and a marked glycosuria, which this time resisted fairly strict adherence to a diet of some 900 calories for about a month. The blood sugar was 300 mg four hours after a small breakfast. Since the patient wished to go on a two weeks auto trip in June, it seemed imperative to return to insulin. She was started May 10 on 4 units of insulin Mulford (40 units) twice a day, with dosage increasing to 14 units twice a day. This did not completely control the glycosuria. Moreover there was a gradually increasing occurrence of wheals at the site of injection, and therefore on May 22 a

change was made to insulin-Lilly (U-40) This was tried for a few days, but wheals continued to appear not only at the injection site but also over the remainder of the body from fifteen to thirty minutes after every dose, and especially at previous injection sites There was also at times a generalized macular itching rash May 30, the patient stopped injections for one week When on June 6 she took one 5-unit dose, it was followed in twenty minutes by violent abdominal cramps, a macular itching rash over her whole body, diarrhea, and a sense of choking Recovery was spontaneous Meanwhile the glycosuria continued uncontrolled

SKIN TESTS

The history of the patient revealed no other symptoms of allergy in herself or her family except that she vaguely recalled that perhaps she had a few hives in early childhood

The following skin tests were therefore made in the hope of finding a brand or special type of insulin to which the patient was not sensitive In each test, 0.01 cc was injected intradermally into the skin of the inner forearm

June 9, insulin (40 units) Squibb's regular preparation, Stearns' regular preparation, Lilly's pure beef preparation, Mulford's regular preparation All reacted with wheals at least 3 cm in diameter within fifteen minutes of the test

*Desensitization Process June 15 1933**

Unit*	Time	Reaction
1/100	0 10 a m	++
1/100	9 45	++

1	5 01	0
5 (hypodermically)	5 20	0

* ++ denotes wheal of at least 1 cm with surrounding hyperemia + wheal of less than 3 mm with surrounding hyperemia ± no wheal but hyperemia 0, no reaction

Pseudopods and hyperemia surrounded the test area There were no constitutional symptoms

June 13, insulin (20 units) Lilly's pure pork A similar reaction occurred

DESENSITIZATION

A desensitization program planned to be effective in one day was now undertaken Lilly's regular Insulin (U-40), made up with sterile distilled water to suitable dilutions, was chosen, this being a commonly available brand known to contain both beef and pork

The original intention was to start with $\frac{1}{100}$ unit intradermally and to increase the dose each half hour as rapidly as tests without reactions could be procured However, $\frac{1}{100}$ unit proved too strong, causing a small wheal and pseudopodia, so that a retreat had to be made to $\frac{1}{1 000}$ unit before physiologic desensitization actually began

The day's program, as it developed, is given in the accompanying table Epinephrine hydrochloride, 1 cc, was kept at hand in a hypodermic syringe but was not required

RESULT

June 15, another dose of 5 units of insulin was given in the office for safety The next day the patient gave herself 5 and 10 units at home and was sugar free on two premeal urine tests June 19 she started on her trip, during which she kept to her diet despite hotel and highway stops, and on 10 to 15 units of insulin daily she remained sugar free almost throughout During all this time there were no allergic symptoms

July 1 the patient returned to San Francisco and that day there began a gradual recurrence of mild generalized itching

and 2 cm hives all over her body, which followed within thirty or forty minutes after injections A new bottle of insulin had been started two days before return The patient was advised to cut down the dose to 2 units per injection for a few days The hives became less but continued to appear occasionally

By October 2 the patient had unfortunately slipped completely from her diet again but had returned to between 5 and 15 units of insulin daily The glycosuria was again uncontrolled but the hives now occurred only at the site of injection or on the arms, only two or three times a week, and that not regularly More especially, the patient observed the reaction during the days after each new bottle was started

A skin test with Lilly's regular insulin, which the patient was then using was repeated at this time and was negative

COMMENT

This case has a bearing on several of the points most frequently discussed in connection with insulin allergy, namely

1 Concerning the occurrence of the phenomenon, these factors deserve emphasis

(a) The patient gave no history of any other allergic tendency This appears to be the most common condition although cases are reported with a definite story of other sensitivities By most authors, insulin hypersensitiveness is classed as an acquired status similar to drug and serum allergies

(b) Supporting the latter view is the quite characteristic fact that the allergic manifestations did not appear at the first exhibition of insulin but came on gradually, increasingly, and more particularly after irregular use of insulin

2 Concerning the reactions themselves, it may be noted that this case presented most of the kinds of reactions that are known to occur These are essentially of two types local and general Local reactions may consist in mild wheals or severe swellings even leading to sterile abscesses, general reactions may either be confined to the skin or involve the whole constitution This case illustrates the mild local reaction, the general urticarial reaction, which is characteristically most marked at the site of previous injections, and the severe constitutional reaction It is also characteristic that the occurrence of shock was preceded for a considerable period by the milder disturbances Other disturbances reported but not shown by this patient are extensive edemas, sometimes with stiffness of joints Death has not been reported

3 On the question of the identity of the provocative agent, whether it is insulin itself or accompanying protein impurities, this case throws no further light That either or both factors may be responsible has been proved by previous writers and the fact that the original skin tests were positive with all brands of insulin suggests that this is one of the cases in which insulin itself was the main cause of difficulty

4 Concerning treatment, the method here used of desensitization with a diluted insulin, the dosage being increased at frequent intervals is one of the many methods that have been employed It differs from other reports only in that the process was begun with a smaller dose and carried through a more complete range of doses before the return to undiluted insulin Other means of treatment consist of desensitizing with a crystalline insulin dilution or in switching from one brand of insulin to another The latter method appears to be successful in cases that present only local reactions and not in cases in which generalized reactions have occurred

The using of a commercial product, as was here done, seems to be simpler than the resort to pure extracts and, for practical purposes, more logical as well

5 Concerning the success of the desensitization process, it is also characteristic that the cure was not complete—that slight local and even mild general skin reactions recurred at intervals The negative skin test after treatment has been found by some authors, while others report positive cutaneous reactions, even with uneventful insulin injections It would seem dangerous in this case, in view of the occasional reactions and in spite of the negative test, to permit any interruption in the administration of insulin unless there is good reason to believe that it could be permanently discontinued, and the latter contingency seems unlikely

6 As in many cases reported, there was a real necessity here for desensitization so that insulin could be used The uncon-

trolled state of the patient's diabetes at that time, even without acidosis, made a potential life hazard out of a trip such as she contemplated, or out of any common infection. In several cases on record the need has been even more acute. Insulin allergy, although rare, may present a very urgent problem when it occurs.

A COMPARISON OF ERYTHROCYTE COUNT, TOTAL HEMOGLOBIN AND CORPUSCULAR HEMOGLOBIN IN SMOKERS AND NONSMOKERS

ORVILLE S. WALTERS, A. M. LAWRENCE KAN

As a basis for explaining a difference observed in the mean hemoglobin level of subjects in the United States and in London, Price-Jones¹ suggested that the motoring habits of American subjects may have produced a slow chronic poisoning by carbon monoxide, as a result of which the oxygen pressure is constantly being slightly reduced and the bone marrow is compensating for the useless carboxyhemoglobin by making more red cells and hemoglobin and producing a relative polycythemia.

Nasmith and Graham² found that guinea-pigs living continuously in a dilute carbon monoxide atmosphere were able to increase the quantity of hemoglobin and the number of erythrocytes to compensate for the loss in oxygen-carrying capacity. This was confirmed by Egdahl,³ who also noted a polycythemia

Comparison of Erythrocyte Count, Total Hemoglobin and Corpuscular Hemoglobin in One Hundred Smokers and Nonsmokers

Series 1 Sampled After Random Activity				
	No. of Subjects	Erythrocytes (Million)	Total Hemoglobin (Gm. per 100 Cc. of Blood)	Corpuscular Hemoglobin (Milli-micrograms)

in human subjects after repeated exposures to small or moderate amounts of carbon monoxide. Experiments by Sayers, Yant, Levy and Fulton⁴ in which six men were exposed from four to seven hours daily over a period of sixty-eight days to mixtures containing two, three and four parts of carbon monoxide in 10,000 parts of air showed that a distinct increase in hemoglobin and red cells occurs under such conditions.

Jenkins,⁵ after investigating the blood of workers exposed to motor exhaust fumes, found that chronic or intermittent exposure to carbon monoxide tends to raise the hemoglobin concentration but he considers the stimulus inadequate to account for the difference cited by Price-Jones.

Gettler and Mattice⁶ after a careful study of the carbon monoxide content of the blood of various groups of subjects, came to the conclusion that smoking is apt to be the most conspicuous factor in determining the carboxyhemoglobin of

an individual under normal conditions when he is not exposed to obvious high percentages of the gas. Hanson and Hastings⁷ found that the hemoglobin of smokers was from 3 to 4 per cent saturated with carbon monoxide, while that of nonsmokers averaged 15 per cent saturation.

The present study compares the mean erythrocyte count, total hemoglobin and corpuscular hemoglobin in smokers and non-smokers, the subjects being 100 healthy male university students between the ages of 20 and 30. Erythrocyte counts are the average of two pipets agreeing within 100,000 cells, and hemoglobin values were obtained with a Newcomer apparatus standardized by the oxygen capacity method. The figures used in this comparison were taken from data gathered for studies of a somewhat different nature.⁸

In practically all smokers studied, the habit was of two or more years' duration, and virtually all used cigarettes exclusively. Those using one package of twenty or more a day have been designated for convenience as "heavy" smokers. The subjects have been chosen from two groups. In series 1, blood samples were drawn at random with reference to physical activity, while in series 2 the subjects were sampled after a half hour rest period in bed.

The data of the accompanying table indicate that neither the differences between smokers and nonsmokers nor those between "heavy" smokers and nonsmokers are significant, since no difference observed is greater than four times its probable error.

SUMMARY

In a group of 100 healthy men, no significant difference was found between smokers and nonsmokers in erythrocyte count, total hemoglobin and corpuscular hemoglobin.

A CASE OF NONFILARIAL ELEPHANTIASIS TERMINATING WITH ALEUKEMOID ANEMIA

RALPH C. LARRABEE, M.D. AND JAMES H. PEERS, M.D.
BOSTON

The combination of chronic edema and hypertrophy of the genitalia and extremities has been a well known disease entity in the tropics from remote antiquity. Probably the first recorded case is that of a woman pictured in an Egyptian bas-relief on a temple wall at Deir el Bahr.

In modern literature the reported cases of elephantiasis, excluding those of the neurofibromatosis of von Recklinghausen, fall into three main classes: the tropical cases of proved filarial origin, the instances of the hereditary elephantiasis of Milroy,¹ and the sporadic nonfilarial cases occurring in temperate climates. In practically all the reported instances longevity has been the rule, and the authors have dealt almost exclusively with the methods and results of surgical treatment.

The case here reported belongs to the sporadic group and is of unusual interest because of its progressive course and fatal termination with profound anemia, with a blood picture suggestive of leukemia, and because of the extreme rarity of postmortem examinations in cases of elephantiasis.

REPORT OF CASE

History—W. F., an American schoolboy, was first admitted to the Boston City Hospital in June 1924 at the age of 13, complaining of swelling of the left thigh of three months' duration. His family history contained no suggestion of elephantiasis. In 1922 an abscess in the right groin had been opened, but no details are available. Swelling of the left thigh began three months before admission. At first soft and painless it had later become brawny, with dull inconstant pain. Five days before admission a soft swelling appeared on the inner surface of the right thigh, just above the knee. Examination on admission disclosed a marked brawny swelling of the entire left thigh sharply demarcated at the knee.

There was also slight soft edema of the inner surface of the right thigh and lower abdominal wall. A faint systolic murmur was heard at the base of the heart. There is no note in the records made at this time of any involvement of the genitalia, or of pallor or other abnormality in general appearance.

With rest in bed and ordinary hospital care the edema of the abdominal wall and right thigh soon subsided, but the brawny swelling of the left thigh persisted. The patient returned to school, and in spite of steady increase in size of the thigh, did perfectly well until June 1925, when the genitalia began to swell.

On readmission in February 1926 the left thigh was about twice the size of the right, not tender, and pitted only slightly on pressure. The lower abdominal wall and right thigh showed a much slighter degree of edema. The penis was definitely edematous, and the scrotum was the size of a grapefruit. For the first time the records speak of "pallor of the skin and mucous membranes."

In March 1926 an exploratory laparotomy was performed by Dr. F. B. Lund with negative results: no tumor, no glandular enlargement and no evidence of filariasis were found in either the abdomen or the pelvis. However there followed some decrease in the swellings, and the patient was able to return to active life.

A minor injury to the scrotum, with resulting infection, brought him to the hospital again in October 1929. The size of the left leg was about as before. The penis was three times normal size, and the scrotum was as large as a football. The lower abdominal wall, genitalia, and upper half of both thighs were acutely inflamed and tender. He also had a discharging ear and tenderness over the mastoid region. The acute inflammatory conditions subsided and after a month he was again discharged.

Pain in the left groin brought him back to the hospital in June 1931. The enlargement of the genitalia had increased somewhat and the left thigh and leg above the ankle were greatly swollen. In July 1931 Dr. H. B. Loder removed a large elliptic section of the scrotum weighing about 5 pounds (23 Kg.). The tissues were found infiltrated with clear fluid which escaped freely at each incision. After several inches of this edematous subcutaneous tissue had been separated, the left testicle was identified, with a hydrocele as large as an orange. The right testicle, without a hydrocele, was also located. Following operation the patient's temperature remained elevated and irregular for a fortnight and then fell to normal.

When examined by the senior author in August 1931, the patient was moderately emaciated and extremely pale, without any characteristic tinge. The area of cardiac dullness was somewhat enlarged to the left, and a loud systolic murmur was heard all over the precordium. Neither spleen nor liver was palpable. The penis was 12 inches (30.5 cm.) in length and $3\frac{1}{2}$ inches (9 cm.) in diameter. What the surgeon had left of the scrotum was several times normal size. The entire left thigh was enormously enlarged. Especially over the genitalia the skin was greatly thickened, brawny and coarsely folded, with a sparse but foul discharge from the folds.

During the month after operation, the patient's general condition improved considerably. This was no doubt due, in part at least, to three transfusions, but the effect of these was transitory. During this period he had occasional slight hemorrhages from the gums.

He improved enough to return to his home September 20, but he was again readmitted October 3, complaining of increasing weakness, dyspnea and fainting spells. There had been no material change in the condition of the genitalia and thighs. On the day of admission there occurred a severe nosebleed lasting three hours. Epistaxis recurred from time to time and there was considerable oozing from the gums. The hemorrhagic tendency was not materially influenced by five more transfusions. October 23, a small retinal hemorrhage was noted in the right eye. The anemia progressed without remission in spite of all treatment and the patient died, Dec. 15, 1931, after an illness of over eight years.

The Blood.—During his various admissions to the hospital the patient's blood was examined many times both day and night, for filariae always with negative results. Of the many hematologic studies made only a few need be given in detail.

Aug. 9, 1924, the hemoglobin was 70 per cent. The red cells numbered 3,620,000 and the leukocytes 5,200, of which 44 per cent were polymorphonuclear neutrophils, 47 per cent lymphocytes, 8 per cent monocytes and 1 per cent mast cells. No immature forms were recorded.

Feb. 1, 1926, the hemoglobin was 85 per cent. Leukocytes numbered 7,000, of which 77 per cent were polymorphonuclear neutrophils, 20 per cent lymphocytes, 2 per cent monocytes and 1 per cent eosinophils. Platelets were normal.

Aug. 10, 1931, the hemoglobin was 25 per cent. Red cells numbered 1,060,000, platelets, 124,000 (Buckman-Hallisey method), and leukocytes 10,450, of which 68 per cent were polymorphonuclear neutrophils, 21 per cent lymphocytes, 1 per cent monocytes and 10 per cent immature cells. The last were mononuclears of rather large size. Their cytoplasm was scanty, nongranular and dense, and it stained deep blue with Wright's stain. Some had short pseudopodia. The nuclei were large and round or more or less indented and stained deeply, frequently presenting one or more large nucleoli. While they were obviously immature forms, their origin could not be precisely determined. Unfortunately the oxidase reaction and supravital staining were not done. The icteric index was 4. The reticulocytes were 2 per cent and the mean diameter of the erythrocytes by eriometer 7.9 microns.

Aug. 14, 1931, the hemoglobin was 28 per cent. Red cells numbered 1,350,000, leukocytes, 3,400, of which 28 per cent were polymorphonuclear neutrophils, 39 per cent lymphocytes, 1 per cent monocytes, 1 per cent eosinophils and 31 per cent immature cells like those seen previously. There was moderate anisocytosis, slight poikilocytosis, and no achromia, polychromatophilia or stippling. The platelets appeared to be greatly reduced.

Subsequent examinations need not be detailed. It is enough to say that, in spite of eight transfusions between July 14 and Nov. 16, 1931, varying in amount from 350 to 500 cc., the anemia steadily advanced. The lowest figures were hemoglobin 13 per cent and red cells 810,000, December 4. The leukocytes varied irregularly from 1,900 to 5,150. The immature cells persisted, though never again reaching the high figure seen in August, the highest recorded thereafter being 6 per cent, December 4. Platelets remained low. Changes in the red cells became more marked as the anemia progressed, but nucleated reds were never recorded.

Other Laboratory Examinations.—The urine showed no essential abnormalities and chyluria was never present. The blood chemistry was normal. Roentgen studies of the bones of the pelvis, legs and skull, made on several occasions, showed no pathologic changes, and one gastro-intestinal series was likewise negative.

Treatment.—In addition to the surgical procedures and transfusions already mentioned, the patient received at various times large doses of iron, liver in various forms, including extract intramuscularly, and arsenic, all without apparent effect.

Pathologic Observations.—The pathologic service had three opportunities for examining material from the patient. The first was the appendix, removed incidentally to the abdominal exploration in March 1926. It was grossly and microscopically negative.

In July 1931 the tissue removed by plastic operation on the scrotum was submitted to the laboratory. It was a large mass of very edematous connective tissue partly covered by epithelium, 30 by 20 by 15 cm. in size, and weighing 2,770 Gm. A large amount of clear lymph exuded on pressure from the cut surface. Unfixed pieces were placed in the incubator over night and subsequently examined for filariae, but none were found. Microscopically the tissue consisted simply of very edematous fibrous tissue with no evidence of chronic inflammation, filariae or mucoid degeneration.

An autopsy was performed one and one-half hours after death. The body was very pale and poorly nourished. The thighs and genitalia were as described. There was slight edema of both feet and ankles, and a hydropericardium and bilateral hydrothorax of moderate degree. The lungs were heavy and soggy and on section presented a small patch of organization in the right apex and a small abscess 1.5 cm. in

diameter in the upper portion of the left lower lobe. The liver was of normal size and was rusty yellowish brown. The other viscera were grossly negative. The bone marrow, both femoral and vertebral, was brownish yellow. No enlarged lymphatics were seen anywhere during the dissection. The greatly enlarged genitalia were found on section to owe their bulk to massive edema of the subcutaneous tissue of the same character as seen in the previous surgical specimen. The testes, when isolated from the great scrotal mass, appeared grossly negative. Examination of the head was not permitted.

Microscopically the lungs showed in addition to edema and old organization, a rather large patch of early pneumonia. The spleen and liver were loaded with brown granular pigment giving the iron reaction, chiefly in monocytes, but there was no evidence of hematopoiesis. The stomach mucosa was well preserved and normal. The testes showed early atrophy, with thickening of the basement membrane of the tubules. Spermatogenesis had completely ceased. There were no spermatozoa in the ducts and no mitoses in the germinal epithelium. Sections of the scrotal wall and penis showed the same edema as in the surgical specimen. No filariae were present, and there was only slight evidence of chronic inflammation, with a few lymphocytes and polymorphonuclears in the penis. The iliac lymph nodes showed some dilatation of the sinuses, which contained serum and a few monocytes and eosinophils but no filariae. The thyroid was microscopically normal.

The microscopic appearance of the bone marrow agreed fairly well with the blood picture during life, as far as its aplastic features were concerned, but it failed to explain clearly the occurrence of immature leukocytic forms repeatedly observed. The marrow was fairly cellular but was not active, as few mitoses were seen. It presented essentially the same structure in vertebra and femur. The cells present were almost all of the granulocytic series, and the great majority were eosinophils, about equally divided in number between mature leukocytes and myelocytes. There were numerous promyelocytes singly and in small clumps. Stem cells were rarely seen, and the erythroblastic series was represented by only a few small clumps of nucleated red cells. Scattered lymphocytes were present. As in the liver and spleen, there were numerous pigment-filled monocytes, an expression, apparently, of severe and prolonged blood destruction. Some of these monocytes contained leukocytes, vacuoles suggesting partially digested red cells, and occasional oval red staining crystalloid bodies. There were but few megakaryocytes.

Cultures taken post mortem from lung and heart blood showed no growth.

COMMENT

Several features of this case are of interest. The existence of nonfilarial elephantiasis is generally admitted and, though rare, our case is not in this respect unique. The senior author saw in 1915 a woman of 22 who had for several years a very large elephantiasis of the left leg. She had never lived in any district where elephantiasis prevailed, all efforts to find filariae in the blood failed, and the condition was not otherwise explained. Then, too, negative blood examination in some reported cases may not be absolutely conclusive. Tissue from at least one case, supposedly nonfilarial, submitted to the laboratory, yielded a single filaria after prolonged search of serial sections.

The swelling of the subcutaneous tissues in tropical elephantiasis is not due so much to the physical obstruction resulting from the presence of the adult parasites in the lymphatic channels as to the more diffuse chronic lymphangitis set up by injury and liberation of embryos. Anything else that can cause a similar chronic inflammation of the lymph vessels may produce similar swelling distal to the obstruction. Thus tuberculous lymphangitis has been described as the etiologic condition in some cases, and massive obstruction by malignant growth or by surgical removal of regional nodes is a relatively common cause of localized elephantiasis. Some cases have been attributed to even a single inflammatory episode or to trauma of war wounds.

In 1892 Milroy reported several cases of a type of elephantiasis that has since become known by his name. It is of congenital origin and is definitely hereditary apparently as an

irregularly dominant (?) mendelian trait. It is generally limited to one or both feet, it is permanent, and it is not associated with constitutional or local symptoms. There appear to be no characteristic finer pathologic changes.

It is difficult to align our case with any of these forms of elephantiasis. There was no discoverable evidence at autopsy of any obstructive lesion of the lymphatics. Clinically it bore some resemblance to Milroy's disease, but it was associated with progressive and constitutional symptoms, it involved the genitalia, and the hereditary factor was lacking. It seems hardly likely that the gross swellings in this case were the sequelae of the abscess in the groin, since it was on the side opposite the initial lesion and antedated it by two years.

Another feature of interest is the changes in the blood during life compared with the appearance of the bone marrow post mortem. While we were unable to identify the immature cells to our complete satisfaction, we regarded them as probably belonging to the lymphocytic series. We thought we were dealing with lymphatic leukemia or, rather, aleukemia. In view of the aplastic rather than frankly leukemic nature of the marrow changes, perhaps the term "leukemoid" would be more appropriate or—to be still more meticulous—"aleukemoid." There was nothing in the blood during life to correspond in any way with the large number of eosinophils afterward found in the marrow.

As to the relation between the elephantiasis and the changes in the blood and marrow, we can only speculate. These changes may have been merely a terminal event in a long continued cachectic state, with no specific relationship to the elephantiasis as a cause of the cachexia except that there were several septic episodes. But one is tempted to speculate further by the fact that both the hematopoietic phenomena and the elephantiasis concerned the lymphatic and reticulo-endothelial systems, and to ask, Was there a common underlying factor?

SUMMARY

A case of nonfilarial elephantiasis in a boy terminated fatally after an illness of eight years. During the last five years there was progressive anemia, becoming hemorrhagic toward the end with leukopenia, thrombocytopenia and numerous immature cells, probably of the lymphocytic series. Autopsy disclosed no cause for the enormous swellings. The marrow showed aplasia of the erythroblastic series and large numbers of eosinophilic cells, mature and immature.

RICHTER'S HERNIA REPORT OF TWO CASES

GALE E. WILSON, M.D., SEATTLE

In 1778 Richter described a "small rupture" in which only a portion of the intestinal wall was incarcerated, and recognized this as being different from the similar appearing Meckel's diverticulum hernia, which was described by Littre in 1700. In 1899 Fowler¹ reported two cases of his own and found ninety-four references in the literature. Between Fowler's paper and one by Rhodes in 1928 there were forty-five additional references, many of which turned out to be Littre's hernia. Two cases were reported in 1929 by Bissell² and one in 1930 by Orr.³ Cattell⁴ in 1933 reported two additional cases and also gave an excellent summary of the literature. He also states that but fourteen operations for this particular type of hernia were reported between 1899 and 1933.

Richter's hernia is described⁵ as "a catching of a portion of the circumference of the bowel, usually a portion of the lower ileum. It is most frequently found in the inguinal femoral, and obturator regions. In about 50 per cent of the cases no lump can be felt."

I am adding two more cases, one because it was almost of the textbook type and ended fatally, the other because it was

of a most unusual type and symptomatology but ended very happily

CASE 1—Mrs E J, an American born widow, aged 75, was seen at home by her family physician, Nov 1, 1932, at which time she complained of pain in the abdomen, swelling of the abdomen, vomiting and obstipation of five days' duration. She stated that about five days previously she had experienced a sudden, but not unduly severe, pain low in the right lower quadrant of the abdomen. Two days later she ceased having bowel movements and began to vomit. Late on the night of the fourth day the family physician was called but did not see the patient until early in the morning of the fifth day, at which time he immediately sent her to the hospital, where physical examination revealed that she was exceedingly emaciated and shriveled. She lay quiet in bed, too weak to move. All her teeth were out, the tongue was heavily coated, the breath was foul, the heart was enlarged to the left midaxillary line, the rate was very rapid and irregular, and the sounds faint. The abdomen was distended well above the level of the pubes and costal margin, rather tense, tympanic throughout and most tender in the right lower quadrant. Peristalsis was visible constantly. No inguinal or femoral hernias were palpable. Rectal examination showed a mass the size of an orange, probably an ovary, pressing into the rectum from above and to the left. A diagnosis of intestinal obstruction was obvious and preparation made for immediate operation, although no favorable prognosis could be offered the family. Under low spinal anesthesia a 4 inch infra-umbilical midline incision was made. A large cystic left ovary was found impacted between the uterus and the rectum, the pedicle was ligated and the mass was removed. A right femoral hernia, incarcerated and of Richter's type, was found involving the lower ileum, with marked angulation of the bowel at the point of incarceration. There was almost complete obstruction at this point. The intestine delivered readily and presented a dark blue area about 30 mm in diameter, which had been held by the hernial ring. The color returned to this area rapidly and it appeared to be viable. A purse string suture was put about the femoral ring, and because of the patient's precarious condition the abdomen was closed without further manipulation. The condition of the patient did not improve and she gradually expired thirty hours after the operation, expelling gas and liquid feces for some hours before her demise. Autopsy revealed a perforation through the incarcerated area with 300 cc of liquid intestinal contents in the pelvis, but with no fibrin or other sign of peritoneal reaction.

CASE 2—T K., a man, aged 56, a bookkeeper, seen in the outpatient department of the Harborview Hospital, Oct 7 1932, complained of palpitation and loss of weight from 178 pounds (81 Kg) a year before to 145 pounds (66 Kg). He was treated medically and got along quite well until March 1933 when he returned with a complaint of bilateral inguinal hernias, for which a truss was recommended. Again he felt well and was not seen until May 20, when he was brought into the emergency ward in a state of collapse. He said that that evening, after eating a bowl of mush, he suddenly felt faint and vomited up a cupfull of bright red blood. He immediately fainted but was revived and brought to the hospital. On admission he complained of cramplike pains in the epigastrium, perspired freely and vomited up a basin full of coffee-ground material and again collapsed. A diagnosis of carcinoma of the stomach was made and he was sent to the medical wards. On the 21st his condition was worse, but he did not vomit again although the abdominal pain persisted. A surgical consultation was requested and I saw the patient that day. The patient was pale, perspiring and very ill. He lay on his right side groaning with pain, which he localized to the epigastrium and said was intermittent in character. The abdomen was slightly distended, especially in the left upper quadrant, tympanic throughout and with definite shifting dullness in the flanks. Rectal examination was negative. There was a small gland in the left supraclavicular region. The temperature was 98 F by mouth and the pulse rate was 100. Red blood cells numbered 4,900,000, white blood cells 6,000, with 72 per cent polymorphonuclears and hemoglobin 78 per cent. A diagnosis of carcinoma of the stomach with probable perforation was made. Preparations for a transfusion were begun and the patient was sent to the operating floor.

Following a transfusion in the morning the patient rallied somewhat, and in the afternoon under infiltration with procaine hydrochloride and gas-oxygen analgesia a 4 inch left midrectus muscle splitting incision was made. When the peritoneum was opened about 300 cc of bloody fluid escaped, but gas was not present. The stomach was somewhat dilated and distended but did not show pathologic changes. The jejunum was markedly distended, and at about the jejunoileac junction there was an incarcerated supravesical hernia of Richter's type. The anterior wall of the intestine was pushed into a sac about the size of a walnut, lying in the right supravesical fold about 3 inches below the umbilicus and extending through the muscles to the anterior sheath of the rectus. It could not be felt from the outside. There was considerable angulation at the point of herniation with a lumen barely the width of a pencil left to the bowel. The hernia was reduced, the incarcerated area appeared viable and the abdomen was closed without drainage.

For the first forty-eight hours after operation the patient's condition was quite grave. Then he demanded food ate, and

Semidiagrammatic sketch showing portion of intestinal wall incarcerated and passing through abdominal wall to posterior surface of anterior sheath of rectus abdominis. A, umbilicus; B, rectus sheath; C, distal loop; D, proximal loop; E, bladder; F, rectum.

made a most uneventful recovery, leaving the hospital on the fourteenth day after operation. One month after leaving the hospital he had gained 10 pounds (4.5 Kg) and is still gaining.

COMMENT

The first case is interesting because of the age of the patient, the long duration of the low obstruction, and the lack of external evidence of a femoral hernia. Some criticism may be offered for not resecting the incarcerated area or doing an enterostomy, but the surgeon and both assistants felt that the area was viable and that the sole chance of saving the patient depended on closing the abdomen as rapidly as possible and returning the patient to bed. There was no peritoneal reaction about the perforation or the bowel contents and it would seem as if the perforation was really more or less incidental to an already fatal issue.

The second case is interesting because of the peculiar onset of hematemesis in a man who had already lost 48 pounds (22 Kg) during the previous year. The "satellite gland" also was misleading, as was the epigastric pain and the free fluid below. The presence of a readily reducible hernia in each inguinal canal could not be overlooked. I cannot find any reference in the literature to a supravesical hernia of Richter's type.

SUMMARY

Two cases of Richter's hernia were seen. One was of the usual femoral type in a woman, aged 75, who had had partial obstruction for five days and who died after operation with perforation through the incarcerated area. The second

case occurred in a man, aged 56, who had bilateral inguinal hernias, a "satellite gland," a weight loss of 48 pounds during the preceding twelve months, and whose first symptom was rather massive hematemesis followed by epigastric pain and distention. At operation he had a Richter's type incarcerated supravescical hernia with almost complete obstruction.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE—In their preparation these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics Dr. Bernard Fantus. The views expressed by the various members are incorporated in the final draft prepared for publication. The series of articles will be continued from time to time in these columns.—ED

THERAPY OF AMEBIASIS

Prophylaxis—This must at present be confined to controlling the spread of the cysts outside the body by 1. Disinfection of the feces and their sanitary disposal, as well as disinfection by boiling of possibly infected water and milk. 2. Avoidance of contaminated foods, such as raw fruits and raw vegetables, and prevention of food contamination by excluding flies and other insects and by periodic examination for cysts of the stools of all persons handling food. 3. Adequate treatment if such persons are found to be carriers of cysts.

Treatment—General principles. As the amebas are embedded in the intestinal wall and in certain cases also in the liver, a remedy may be required that reaches them through the blood stream. This is preeminently furnished by the injection of emetine. As amebas are also free in the alimentary tract and these must be reached by the amebicide passing down through it, it is also necessary to administer by mouth either chiniofon or acetarsone. As these agents are also absorbed into the blood stream, they furnish a combined treatment that generally suffices in all but the most severe cases. The treatment must be continued intermittently for quite some time until the stools are free from cysts in order to prevent relapses and transmission of the disease to others. Besides this, the ulcerative colitis requires careful dieting and oral as well as in its later stages, colon medication. Finally, the patient's general condition must be improved, as these patients are often undernourished and healing does not readily occur until general nutrition has been improved. It is necessary to distinguish between the treatment of (a) severe cases, (b) mild cases and (c) cases in which there is liver abscess.

(a) *Severe Cases*—1. "Specific" remedies are best given in courses.

First period. Emetine hydrochloride is most valuable for the control of the dysenteric symptoms. It is given (prescription 1) in sterile physiologic solution of sodium chloride hypodermically in doses of 0.06 Gm. Usually seven doses suffice for the control of the acute symptoms, but twelve doses should not be exceeded. A course of emetine should be followed by a period of

rest of at least a month. Emetine may cause diarrhea, which must not be confused with that of dysentery. It may also be responsible for peripheral neuritis, and even cardiac deaths have occurred as a result of excessive emetine therapy. Hence emetine treatment should be discontinued at the first evidence of weakness, which may manifest itself earliest in the neck.

Second period. As emetine fails to cure in about two thirds of cases, one should on the sixth day, while the emetine injections are still being continued, give the patient one of the following drugs by mouth: chiniofon (jaten, anayodin or quinoxy) (prescription 2), or vioform an analogous substance (prescription 3). If further experience substantiates the claims made for it, vioform should be preferred because it is considerably cheaper. If these fail to give a satisfactory result, one may prescribe, as succedaneum carbarsone (prescription 4), which is possibly somewhat more toxic. The carbarsone treatment must not be repeated for ten days and each dose of the second course should be watched for possible arsenic intoxication: gastro-intestinal irritation, respiratory tract congestion, neuritis, renal damage and visual disturbance. If motile forms persist, carbarsone retention enemas (2 Gm to 200 cc) in warm sodium bicarbonate (2 per cent) solution, preceded by sodium bicarbonate cleansing enemas repeated every other night for five times, unless in the meantime the symptoms subside. During this period the drug should not be given by mouth for fear of too great arsenic absorption.

PREScription 1—Emetine

R Emetine hydrochloride hypodermic tablets 0.06 Gm
No vi
To be dissolved in 2 cc of sterile physiologic solution of sodium chloride and injected hypodermically (Price index for course 71)

PREScription 2—Chiniofon

R 100 chiniofon enteric pills 0.25 Gm
Four three times a day for one week (Price index for course 370)

PREScription 3—Vioform

R Vioform 15.0 Gm
Divide into 60 capsules. One three times daily for ten days. Repeat course after a week's rest period (Price index for course, 125)

PREScription 4—Carbarsone

R 20 Carbarsone capsules 0.25 Gm
One capsule twice daily after meals for ten days (Price index for course 102)
Children's dosage:
From 2 to 4 years 0.06 × 3 × 10
From 5 to 8 years 0.09 × 3 × 10
From 8 to 12 years 0.12 × 3 × 10
May be given in milk, orange juice or jelly

Third period. For three months the patient should be given one full day's treatment each week to prevent a relapse.

The essential thing in the successful treatment of amebiasis is that each course must be complete in itself until three stools are free from amebas and their cysts. A relapse must be treated as fully as the original attack, except that emetine must not be used repeatedly.

2. Absolute rest in bed is necessary, even if symptoms are not extremely severe, with use of the bed pan. A rubber sheet should be placed below the patient, and warm coverings used. Proper care should be given the skin, especially to prevent bed sores.

3. The diet for the first twenty-four hours should consist of nothing but water, then clear liquids, rice and barley water, whey, albumin water, soups and tea may be given. Sugars should be avoided, saccharin being used. Later, cereal gruels, toast, eggs, cocoa and scraped meat may be given, with a gradual return to a

normal low residue and vitamin rich diet. Fruits must not be given until late, except orange and lemon juice.

4 Evacuation of the bowel at the onset and for the first two or three days should be assured, either castor oil or a saline cathartic being given. A saline cathartic or liquid petrolatum is also important during convalescence to prevent irritation of ulcers by hardened feces.

5 Absorbents and protectants should be given during the next stage of treatment. Bismuth subcarbonate, 0.5 Gm hourly up to 4 Gm every three hours, may be administered, and, as the disease process is chiefly low down in the colon, kaolin or charcoal enemas, or bismuth subcarbonate, 15 Gm in warm sweet oil, 250 cc, or, possibly best, powder insufflation of equal parts of bismuth subcarbonate and of calomel applied through a powder blower.

6 For sedatives, one should preferably use atropine and epinephrine for relief of colic. If these do not suffice to secure rest, especially during the night, one should use an opiate, which may be added to the bismuth subcarbonate or given in a suppository. It is well to combine it with atropine. Bowel movements must not be diminished to too great an extent, as this may increase systemic intoxication. Against tenesmus due to ulceration, iodoform in olive oil (prescription 5) may be useful.

PREScription 5—Iodoform in Olive Oil

R Iodoform	8.00 Gm
Olive oil	90.00 cc

Keep on ice. Inject one tablespoonful into the rectum every four to six hours. Morphine subcutaneously may be required.

7 As symptomatic treatment for collapse, in the choleraic type, physiologic solution of sodium chloride, Ringer's solution or 10 per cent dextrose phleboclysis may be used. (See also collapse.) During convalescence, one should treat anemia.

(b) *Mild Cases*—Rest in bed, a special diet and laxatives may not be required in mild cases and emetial toxicity. This leaves chimofon or vioform as the treatment of choice in cases that lack careful supervision.

(c) *Cases in Which There is Hepatic Abscess*—Hypodermic emetine injection in the presupplicative stage may prevent the necessity of operation and in most cases should precede the consideration of surgical treatment. After roentgen examination to determine the location, repeated aspirations followed by injection of the cavity with emetine may suffice to cure abscesses not infected with bacteria and to prevent bacterial infection, which so commonly supervenes. In obstinate cases and—if mixed infection is present—at the very first, free incision and drainage are demanded.

Graham Lusk's Student Days—The Munich of the day of which I speak was a simple old-fashioned German town. The first summer that I spent there I lived on the Karlstrasse, having taken a room above a beer hall at five dollars a month. The good frau who rented the room gave me a roll without butter and a cup of coffee in the morning for five cents.

I could live on \$50 a month, but my average was \$75 monthly. I well remember the ceremony of moving from one lodging to another. A diensman brought a small hand cart. On this were placed my worldly goods including my books and my beer mugs. A German student lamp with a green shade crowned the load. While escorting this picturesque vehicle I met Mr and Mrs Henry Holt old family friends who had a hearty laugh over the scene.—Lusk. Graham quoted by Light A. E. Graham Lusk *Yale J Biol & Med* 6:487 (May) 1934.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
H. A. CARTER, Secretary

HI-ARC CARBON ARC LAMP ACCEPTABLE

The Liebel-Flarsheim Company, Cincinnati, manufactures and offers for sale to the medical profession an ultraviolet generator designed for therapeutic purposes and known as the Hi-Arc.

HI-ARC Ultra
violet Lamp
Acceptable

It is a carbon arc lamp and the arc burns within a closely confined refractory chamber open only in front. Radiant energy is emitted through this oval opening. The electric arc, therefore, takes place within a relatively chemical inert atmosphere, sealed from the air by emerging gases formed when the materials in the carbons vaporize.

One Hi-Arc unit was investigated in a laboratory acceptable to the Council on Physical Therapy. The report indicated that the ultraviolet energy emission met the requirements of the Council. The power consumption is approximately 900 watts and the shipping weight is 200 pounds.

The unit was examined in a clinic acceptable to the Council and it was found that it gives satisfactory service. The Hi-Arc, therefore, is included in the list of accepted devices.

LINDE OXYGEN THERAPY REGULATOR TYPE R-51 ACCEPTABLE

The Linde Oxygen Therapy Regulator Type R-51, manufactured by the Linde Air Products Company, New York City, is a diaphragm reducing valve, of the two stage or double reduction type. The company recommends it for use with nasal catheters, nasal inhalers and face masks, oxygen tents and oxygen chambers. The principal elements, such as the body and cap, are pressure forged bronze. The regulator is provided with a threaded union nut and nipple with ball seat for attachment to standard commercial oxygen cylinders.

The regulator has two outlets, both of which are equipped with silencers. The A outlet is used for flows up to eight liters per minute. The B outlet is used for flows of from 3 to 24 liters per minute. A plug attached to the regulator is used to close the outlet not in service.

There are two pressure gages. The cylinders contents gage indicates the supply of oxygen in the cylinder in liters, cubic feet and fractions of a full cylinder. The flow indicator registers volume delivery from either of the two outlets. However, the calibration of the gage dial in relation to the outlet orifices of known diameter makes it possible to show delivery in terms of liters per minute rather than in pounds per square inch.

The regulator is provided with a safety release of the bursting disk type, which will relieve any possible excessive pressure in the low pressure side of the regulator.

The first reduction stage automatically reduces the full cylinder pressure of 2,000 pounds per square inch to less than 200 pounds per square inch with the result that the second stage, that which is responsible for the delicate control of the amount of oxygen flowing to the patient, is working against a constant pressure of 200 pounds rather than against a pressure that varies between 0 and 2,000 pounds. By setting the flow adjusting screw, which actuates the valve in the second stage, this pressure of 200 pounds per square inch is further reduced until the proper liter flow is secured by its passage through a carefully calibrated orifice. Of course, when the cylinder pressure falls below 200 pounds the first stage valve remains open so that the cylinder can be emptied of oxygen.

Linde Oxygen Therapy
Regulator Type R-51

The regulator was investigated in a clinic acceptable to the Council. It was used for about six months and proved satisfactory from the standpoint of flow as checked by a water-flow meter and a float-type meter.

The Linde Oxygen Therapy Regulator is included in the Council's list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

AMINOPHYLLINE (See New and Nonofficial Remedies, 1934, p. 439)

Aminophyllin-Dubin—A brand of aminophylline-N N R. Manufactured by the H E Dubin Laboratories Inc New York. No U S patent or trademark.

Ampules Solution Aminophyllin Dubin 0.24 Gm, 10 cc

Ampules Solution Aminophyllin Dubin 0.48 Gm, 2 cc

Suppositories Aminophyllin Dubin 0.36 Gm

Tablets Aminophyllin Dubin 0.1 Gm

DIPHTHERIA TOXOID, ALUM PRECIPITATED (REFINED)—(See New and Nonofficial Remedies 1934, p. 393)

The Gilliland Laboratories, Inc., Marietta, Pa.

Diphtheria Toxoid, Alum Precipitated (Refined)—Prepared from a veal broth culture of *B. diphtheriae* which yields toxin having an L-t dose of not more than 0.2 cc. The toxin is treated with 0.4 per cent U S P formaldehyde until the toxicity is so reduced that five human doses will cause no local or general symptoms of diphtheria poisoning when injected subcutaneously into guinea pigs weighing 300 Gm. The toxoid is precipitated with a solution of aluminum and potassium sulphate. The precipitate is washed and then suspended in physiologic solution of sodium chloride. The finished product contains merthiolate in a concentration of 1:10,000. The product is tested for antigenic potency according to the method prescribed by the National Institute of Health. Guinea pigs weighing 500 Gm. given one human dose must produce at the end of six weeks at least two units of diphtheria antitoxin in each cubic centimeter of blood serum. Marketed in packages of one 1 cc vial (one immunization), ten 1 cc vials (ten immunizations), one 10 cc vial (ten immunizations).

REPORTS OF THE COUNCIL

NUMEROUS INQUIRIES ARE ADDRESSED TO THE COUNCIL CONCERNING ALKALINE OR NEUTRAL PREPARATIONS OF PROCAINE AND CONCERNING STABILITY OF THE SOLUTIONS. THE COUNCIL ON DENTAL THERAPEUTICS OF THE AMERICAN DENTAL ASSOCIATION PUBLISHED A REVIEW IN ANSWER TO SIMILAR QUERIES RECEIVED BY THAT COUNCIL UNDER THE TITLE STOCK SOLUTIONS AND MIXTURES FOR LOCAL ANESTHESIA (J A D A JUNE 1932, PP 1046-1051). THE COUNCIL ON PHARMACY AND CHEMISTRY HAS DEEMED IT EXPEDIENT TO AUTHORIZE PUBLICATION OF THE FOLLOWING ABSTRACT OF THE REPORT OF THE COUNCIL ON DENTAL THERAPEUTICS IN DOING SO THE COUNCIL MAKES GRATEFUL ACKNOWLEDGMENT TO THE COUNCIL ON DENTAL THERAPEUTICS FOR PERMISSION TO USE THIS MATERIAL.

PAUL NICHOLAS LEECH Secretary

INFILTRATION ANESTHESIA

There have been and are a multitude of solutions for local or infiltration anesthesia on the market. These are of such variation in reaction (pH), nature of preservative, and so on, as to render impossible any determination of the cause of unsatisfactory results or reactions, whether due to the product, to the method employed or to idiosyncrasy of the patient. In recent years, except for sporadic or regional though evanescent popularity of other compounds, procaine hydrochloride, either alone or with epinephrine, has come into almost universal use. For many years such solutions were made up when needed with the use ordinarily of either sterile water or physiologic solution of sodium chloride. During that period it was not unusual to find stock solutions under proprietary names marketed, ordinarily, in large bottles, which rendered them unsatisfactory through the need of employing undesirable amounts of preservatives. The stability and sterility of such solutions were usually questionable and there seems to be no justification for the use of chemical sterilizing agents since boiling is so effective.

The ampule and its rubber-tipped or rubber-stoppered hermetically sealed counterpart appeared next and offered the advantage of smaller amounts of the solution, avoiding the old age that the contents of a larger bottle might attain. However, preservatives are as necessary in such containers and either the preservative, the container or both became the main advertising feature of such products though the active drugs remained the same.¹ Such preparations had a natural appeal, of course, in that they saved time, particularly for the dental practitioner, that otherwise would have been consumed in preparing his own solutions. All such preparations present two common disadvantages in that some preservative (of a potentially irritating nature) must be used and a considerable degree of acidity must obtain. Over long periods of time, or when exposed to adverse conditions of heat and light, the sterility and potency of these solutions become questionable.

It was shown by O Gros in 1910 (confirmed by A Laewar in 1912 and Sollmann in 1918) that solutions of procaine hydrochloride alkalinized with sodium carbonate possess from two to four times greater penetrating power on nerve sheaths and mucous membranes.² Other investigators have noted the same results using different alkalinizing agents. Apparently, in the attempt to produce permanent solutions it has become the custom to use a pH as low as 3.3 in order to postpone the decomposition of epinephrine. This has been the subject of criticism because of the wide discrepancy between the reaction of the stock solutions and the pH of normal tissue fluids, and it might seem to be equally subject to the objection that the added penetrating powers of procaine base are not used to advantage. It is thus pointed out that not enough is known concerning the stability of alkaline solutions of procaine, and they should therefore be freshly prepared. Many clinics and hospitals prefer the use of a fresh solution which may be made by the hospital pharmacist, or by the nurse. A solution of 1 Gm of sodium carbonate or sodium bicarbonate in a liter of water is boiled thoroughly and set aside under sterile precautions. When a 2 per cent solution of procaine is desired there is added for every 5 cc of the foregoing solution a tablet of procaine hydrochloride 0.1 Gm (1½ grains). While such a solution liberates but one fourth of the available procaine as base, it has the advantage that there will be no excess carbonate remaining to cause irritation. The equation may be stated

The pH of such a mixture is about 7.8 only slightly higher than that of tissue fluids, and operative anesthesia is said to be produced in about one-third the time required with an acid preparation. It has the possible disadvantage of requiring immediate use since cloudiness appears an hour or so after preparation. Procaine borate requires no alkalinization other than the liberation of its own anion by hydrolysis, and it is said to be equally efficient. Until the manufacturers who are now attempting to produce stable alkaline stock solutions succeed the foregoing method should recommend itself. In making such solutions it is quite obviously of great importance to know the exact composition of all tablets and a statement to that effect should appear in plain, clear type on all containers. Sealed glass ampules, but not bottles with a complete statement of composition and date of manufacture may be considered satisfactory within a reasonable length of time after marketing. Concerning preservatives and antioxidizing agents it may be said that proof of their harmlessness, worth and composition should devolve on the manufacturer alone and not on the trial and error routine of indiscriminate clinical use. Until a satisfactory preservative is found, it is suggested that bacteriologic studies be made from time to time of products obtained from the open market. The *Journal of the American Dental Association* concludes

"In summary it may be said that recent experiences point to the desirability of using freshly prepared alkaline solutions of procaine hydrochloride and epinephrine for local anesthesia. Stock solutions in bottles, ampules or cartridges are not without objection. The burden of proof rests upon those who would claim the contrary."

¹ At present a mixture of sodium sulphite and hydrochloric acid is commonly used though the quantity is secret and varies with the manufacturer.

² This property was shown to depend on the formation of procaine base.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORT
RAYMOND HERTWIG Secretary

NOT ACCEPTABLE

MENN'S BUTTER-FLAKE BREAD (Sliced)

The Menn's Baking Company, Austin, Texas, submitted to the Committee on Foods a white bread called Menn's Butter-Flake Bread, prepared by the sponge dough method. It contained white flour, water, sucrose, shortening, dry skim milk, salt, malt syrup, yeast and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

Discussion of Name—The name "Butter-Flake Bread" indicates that the baking formula contains sufficient milk fat or butter to impart to the bread a distinctive and characteristic butter flavor and nutritional values inherent to butter, making the bread different from the usual white bread. Butter, however, is not an ingredient and the skim milk used contributes little milk fat. The name, therefore, is inappropriate and misleading. Names for foods should truthfully identify their nature and not misrepresent their composition or nutritional values.

The analysis submitted showed a moisture content of 49 per cent for the entire loaf, 11 per cent in excess of the maximum set by the United States Department of Agriculture definition and standard for bread.

The manufacturer was informed of this opinion but has not manifested willingness to change the name or properly reduce the moisture content in accordance with the Committee's recommendations. This bread will therefore not be listed among the Committee's accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

CAREY-IZED SALT

PIONEER BRAND TABLE SALT

Manufacturer—The Carey Salt Company, Winnfield, La.

Description—Table salt containing approximately 1 per cent added magnesium carbonate. The same as Carey's Salt (Free Running) (THE JOURNAL, Aug 26, 1933, p 676).

Claims of Manufacturer—For table and cooking uses of salt. The added magnesium carbonate tends to preserve the free running qualities. Does not cake or harden in the package.

(a) WATSON'S CRYSTAL WHITE TABLE SYRUP

(b) ROYAL 'W' GOLDEN SYRUP

Distributor—The Watson Wholesale Grocery Co., Salina, Kan.

Packer—Bliss Syrup and Preserving Co., Kansas City, Mo.
Description—(a) A table syrup, corn syrup sweetened with sucrose syrup and flavored with vanilla.

(b) A table syrup, corn syrup flavored with refiners' syrup.
Manufacturer—(a) Same as Bliss Pancake Crystal White Brand Syrup (THE JOURNAL Nov 18 1933 p 1635).

(b) Same as Bliss Pancake Brand Golden Syrup (THE JOURNAL, Oct 28 1933, p 1393).

Claims of Manufacturer—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

STOKELY'S FOR BABY SPECIALLY PREPARED STRAINED APRICOTS

SWEETENED WITH SUGAR, CONTAINS SULPHUR DIOXIDE
Manufacturer—Stokely Brothers & Company, Inc., Indianapolis

Description—Sieved dried "sulphured" apricots, slightly sweetened with sugar, largely retaining the vitamins and all the minerals of "sulphured" dried apricots.

Manufacture—Choice dried "sulphured" apricots are carefully inspected to eliminate unsuitable material, washed twice, and soaked over night in cold water, the swelled apricots and juice are transferred to a steam jacketed, closed kettle, heated at approximately 91 C until soft, and are drawn off and sieved in a steam atmosphere through a screen with openings of a size to produce the desired fineness and texture. A definite amount of sugar and hot water are added for sweetening and adjusting the consistency. The batch is heated to filling temperature, immediately filled into enamel lined cans and processed.

Analysis (submitted by manufacturer) —

	per cent
Moisture	75.8
Total solids	24.2
Ash	1.0
Fat (ether extract)	0.1
Protein (N X 6.25)	1.3
Reducing sugars as dextrose	14.2
Sucrose	0.5
Crude fiber	0.8
Total acidity as malic acid	1.2
Carbohydrates other than crude fiber (by difference)	21.0
Sulphur dioxide	0.02
Alkalinity of ash (cc. normal acid per gram ash)	7.2
pH	4.3

Calories—0.9 per gram 26 per ounce

Vitamins—The natural vitamin content is retained in large measure in the manufacturing process by the use of equipment and procedure which exclude incorporation of air, the fruit material is exposed to steam only.

Claims of Manufacturer—Supplementary to the infant milk diet, and valuable for children and adults on soft diets. Has smooth consistency and supplies desirable bulk without roughness. The straining renders the nutrient content readily available for digestion. Scientifically prepared to retain in high degree the natural flavor, mineral and vitamin values. Seasoned to bring out full flavor and packed in enamel lined cans. Requires only warming for serving.

VITAMIN D FORTIFIED PASTEURIZED MILKS

- (1) BROCK-HALL
- (2) EDGEMAR
- (3) FOX'S GUERNSEY DAIRY
- (4) GOLDEN GUERNSEY DAIRY CO-OPERATIVE'S
- (5) JOHNSTOWN SANITARY DAIRY COMPANY'S
- (6) SIBLEY FARMS MODIFIED
- (7) FARMERS DAIRY ASSOCIATION
- (8) UECKE DAIRY COMPANY'S

Distributors—(1) Brock-Hall Dairy Company, New Haven, Conn., (2) Edgemar Farms, Venice, Calif., (3) Fox's Guernsey Dairy, Waukesha, Wis., (4) Golden Guernsey Dairy Co-Operative, Milwaukee, (5) Johnstown Sanitary Dairy Company, Johnstown, Pa., (6) Jersey Milk Service, Inc., Worcester, Springfield, Mass., (7) Farmers Dairy Association, Portland, Ore., (8) Uecke Dairy Company, Eau Claire, Wis.

Bottler—(3) and (4) Vitek Laboratory, Milwaukee

Description—Bottled pasteurized milk fortified with vitamin D (vitamin D concentrate prepared from cod liver oil), contains 400 U S P X (Revised 1934) vitamin D units per quart.

Preparation—The milk complies with legal requirements and is pasteurized by the standard holding method. See THE JOURNAL July 1, 1933, page 34, for description of fortification with vitamin D.

Vitamins—The vitamin D concentrate used and the fortified milk are regularly tested biologically. Clinical investigation shows this milk to be a reliable antirachitic agent if proper amount is used.

Claims of Distributors—Vitamin D fortified, antirachitic pasteurized milk having otherwise the flavor and food values of usual pasteurized milk.

A CRYSTALLINE HORMONE FROM THE SUPRARENAL CORTEX

In his classic memoir "On the Constitutional and Local Effects of Disease of the Suprarenal Capsules," published in 1855, Addison remarked that practically nothing was known of suprarenal physiology. Marked advances have been recorded since that time. First is the clear understanding that ablation of the suprarenal glands or their destruction through disease results in death. Thus they are definitely established as organs indispensable to life. The suprarenal medulla is the largest mass of chromophil tissue present in mammals. The discovery that it elaborates a potent substance, epinephrine, promptly directed attention to the medullary portion of the suprarenal structures. Despite the value of epinephrine—a product now readily synthesized in the chemical laboratory—in medicine and its demonstrated physiologic role, notably as a sympathomimetic substance, it can no longer be regarded as the presumptive life-saving hormone. The latter honor belongs to some constituent of the suprarenal cortex. The cortex is not embryologically related to the medulla, and the juxtaposition of the two has not yet received an adequate explanation.

Several American investigators have made great strides in the preparation of highly potent concentrates of the cortical principle. This follows the general research program and progress employed in the case of several other hormones. Some of these products have been effective in replacement therapy and have already found application in practical medicine. Efforts have been made to "standardize" the cortical extracts in terms of their effect on suprarenalectomized animals. The work of Stewart and Rogoff in Cleveland, of Hartman in Buffalo, of Swingle at Princeton and of Britton of the University of Virginia, together with that of their various co-workers, has greatly advanced our knowledge. Of late there have been rather embittered debates as to the modus operandi of the hormone. Its alleged effects on metabolism, carbohydrate mobilization and the blood sugar level, blood volume, water

exchange and related phenomena have been drawn into the somewhat acrimonious discussion.

Whatever may be the final conclusion as to the nature of the action of the cortical hormone, a great step in advance seems to have been made in the isolation in crystalline form, of the essential principle. This is, as always, the first step in the direction of the desired goal of the synthesis of physiologically important substances. Success in the case of the suprarenal cortical hormone is due to Dr. E. C. Kendall and his collaborators¹ at the Mayo Clinic. It will be recalled that Kendall was the first to isolate thyroxine from the thyroid gland. Grollman² had previously separated the cortical hormone in crystalline form, but it is doubtful, Kendall believes, whether the substance was obtained in pure form. The empirical formula is $C_{26}H_{20}O_6$, with a molecular weight of 350. The complete chemical identification and eventual synthesis of this cortical hormone remain to be accomplished. Biochemistry may well be proud of the great advance already made. It is a noteworthy achievement.

NATURAL PIGMENTS AND VITAMINS

In accordance with recent studies in nutrition there is a growing tendency to associate highly pigmented natural foods with peculiar nutritive potency¹. The information on which this view is based has become available largely through the laboratory investigations involving the use of experimental animals—the so-called biologic assay. Perhaps the most striking correlation between natural coloring material and nutritional value that has thus far been established relates to carotene. This natural pigment accounts for the vitamin A potency of many fruits and vegetables, occurs in butter and, on the basis of quantitative measurements, is transformed into vitamin A in the animal body to a noteworthy extent. Along with these more strictly biologic studies on carotene there has been carried out a series of intensive experiments dealing with the chemical constitution and relationships of a series of other plant and animal pigments. The account of progress in this direction leads directly to one of the greatest biochemical achievements of the present decade—the determination of the chemical structure of the vitamins.

In a summary of recent investigations on the carotenes and flavines, Kuhn² has emphasized the nutritional significance as well as the chemical relationship of certain members of these groups of compounds. Carotene is a compound of carbon and hydrogen, it,

² Grollman Arthur and Firor W. M. Observations on the Hormone of the Adrenal Cortex. Am. J. Physiol. 101: 46 (June) 1932.
¹ Pimenton Peppers and Vitamin A. Current Comment. J. A. M. A. 101: 1972 (Dec. 16) 1933.

² Kuhn R. J. Soc. Chemical Industry. 52: 981 1933.

together with lycopene found in tomatoes and the xanthophylls occurring in egg yolk and in many plants, is insoluble in water but dissolves in fats and fat solvents. The entire group constitutes the so-called lipochromes. Several isomeric carotenes have been prepared, these differ among themselves in such physical constants as melting point, specific optical rotation and spectral absorption. However, the most striking difference from the biologic point of view is that relating to vitamin A potency. Beta-carotene is more effective as a source of vitamin A than is either the alpha or the gamma form. Beta-carotene consists of two carbon rings of the beta ionone type attached to a chain of nine conjugated double bonds. When it is symmetrically divided into two parts, the primary alcohol derivative of each part becomes a molecule of vitamin A. Both alpha and gamma carotene have only one of the ionone rings, which accounts, on the basis of structural organic chemistry, for their inferiority as sources of vitamin A. The same argument explains the failure of lycopene to show any vitamin A activity. Not all of the natural pigments so far examined have as large a molecule as does carotene, but it has been shown that several of them—the pigments in annatto and in saffron, for instance—bear definite structural relationship to it.

The flavines constitute a second group of natural pigments that have received considerable attention. In contrast to the lipochromes, this group (the lyochromes) is soluble in water and contains nitrogen. These substances are widely distributed in nature among plant and animal tissues, and attention has recently been called to the fact that there is a close similarity between their occurrence and that of vitamin G, sometimes referred to as the pellagra-preventive factor. Ovoclavine from egg white and lactoflavine from milk have been prepared in the form of beautiful orange brown needles. Chemical and physical examination of the crystals indicate that the coloring material from these two sources is identical. When this material was given to experimental animals whose growth had been restricted because of a lack of vitamin G in the ration, resumption of growth was brought about by as little as 0.000005 gram. This is of the order of magnitude of the quantity of beta-carotene needed to cause the symptoms of vitamin A deficiency to disappear, and it appears that the crystals of flavine either are identical with vitamin G or carry this food factor as a contaminant. There seems little reason to doubt that with the final chemical characterization of ovoclavine and lactoflavine another of the vitamins will have been completely identified.

In the past a close collaboration between the biologic and the organic chemical laboratory has been productive of much fundamentally valuable research notably in connection with proteins and amino acids and also with hormones. Recent investigation in the field of vitamins shows again that history will repeat itself in scientific endeavor as well as in other fields of interest.

The close connection between certain of the natural pigments and indispensable nutritional factors emphasizes again the wisdom of a wide choice of foods and of consuming some foods in the uncooked natural state.

PAIN IN GASTRIC AND DUODENAL ULCERS

Pain is the chief clinical symptom of ulcer. This fact is sufficient to indicate why it is important to ascertain the mechanism by which the pain is brought about. It is far more difficult to investigate the sensibility and the sensations of internal organs than to study these features in the cutaneous areas that are more readily subjected to direct observation and experiment. According to most writers, pain is not produced in the viscera by handling or even by cutting, it appears to be associated with excessive action, stretching, and inflammatory conditions that involve the sensitive parietal layer of the peritoneum. Perhaps this is why the pain of gastric ulcer has been attributed so often to pylorospasm. One reads, for example, that the production of ulcer pain because of hypersecretion of hydrochloric acid is highly improbable, for it is alleged that the pain may be severe when the acid secretion is diminished, and vice versa. That is why Brown¹ has asserted that the relief which follows ingestion of food and soda is in all probability due to relaxation of the pylorospasm that facilitates emptying of the stomach. The view has perhaps been fortified by demonstrations that so-called hunger pangs are due to pronounced motor activity of the stomach.

In contrast with this is the contention that hydrochloric acid is the irritant normally present in the gastric content, which constitutes an adequate stimulus to the pain-producing mechanism of a sensitive peptic ulcer. Years ago B. W. Sippy, an ardent student of gastric ulcer, stated that the pain and discomfort of uncomplicated ulcer are due to the irritative action of hydrochloric acid on the nerves exposed in the ulcer. Despite this there are recurrent statements in the literature of gastro-enterology intimating that varying amounts of hydrochloric acid in concentrations up to at least 0.2 per cent have been introduced into the empty stomach without producing distress either in normal persons or in patients with ulcer. Thus the pendulum of opinion has been swinging between two conflicting views in a long succession of clinical investigations since before the beginning of the century. The methods employed have included clinical observation of the acidity of the gastric content during spontaneous distress, the production of ulcer pain by physiologic solutions of hydrochloric acid and by stimulation of gastric secretion with histamine hydrochloride, kymographic and roentgenologic studies of the stomach during distress, and observations on the effect of atropine sulphate and of calcium chloride on ulcer pain.

¹ Brown, T. R. *Cecil's Text Book of Medicine*. Philadelphia: W. B. Saunders Company, 1930, p. 691.

Accepting ulcer pain as a fact, it must be admitted that there is a lesion present, that the nerve supply is abundant, and that in some way an adequate stimulus is applied to some nerve mechanism with consequent perception of pain. On this basis Palmer and Heinz² of the Department of Medicine at the University of Chicago have devoted attention to the manner in which pain arises, to its site of origin and to the nature of the adequate stimulus, rather than to the type of nerve or nerve ending excited, the pathway of the pain or the manner in which it is referred. The championship of the theory of chemical sensibility is forcefully sustained. According to their studies, ulcer pain arises at the site of the lesion. It is not directly dependent on pylorospasm, gastric motility or intragastric pressure but depends on the presence of an adequate stimulus acting on an irritable pain-producing mechanism located in or adjacent to the lesion itself. The enhanced irritability of the tissue in or about the lesion is dependent on the presence and continued action of acid gastric juice, conversely, desensitization may be produced by continued neutralization. According to Palmer and Heinz the adequate stimulus may be either (a) mechanical, due to peristaltic traction or local spasm, or (b) chemical, due to the acid reaction of the chyme. The usual stimulus is the free hydrochloric acid of the gastric content. The action of the stimulus, be it mechanical or chemical, is probably exerted directly on nerves rendered hyperirritable by inflammation resulting from the destructive effect of acid gastric juice.

Current Comment

MOTION PICTURES OF BACTERIA

Since the introduction seventy-five years ago of the word Schizomycetes, the simpler bacteria have been generally regarded as unicellular plants multiplying solely by symmetrical cell division. The possibility of asymmetrical fission, with the production of daughter cells or different hereditary characters, has been denied. Reproduction by budding rather than by simple cell divisions has not been considered possible. Yet both of these bizarre types of reproduction are common, if one is to credit the photographic evidence recently reported by Wyckoff¹ of the Rockefeller Institute. To follow the finer details of bacterial growth, he studied motion pictures of pathogenic bacteria planted on agar-coated cover slips. With certain species he found that proliferation is invariably in accord with the classic nomenclature, or by an equivalent process of "coccoid division." Under certain environmental conditions, however, multiplication of many species occurs not by this conventional method but by single or multiple budding or sprouting. Rup-

ture apparently occurs of one or more portions of the cell wall. Small amounts of protoplasm are extruded and develop into new bacteria before being pinched off. Intracellular granules are readily demonstrated in many senescent bacteria. Bacteria in which such granules are just beginning to appear proliferate normally if transplanted to fresh culture medium. Unlike nuclei, however, these granules are distributed asymmetrically to the resulting daughter cells, and these young cells soon become internally homogeneous. In bacteria with fully formed granules, however, no proliferation is demonstrable. Nor is proliferation even observed with individual granules freed by disintegration of bacteria. Wyckoff therefore regards the granules demonstrable by photographic methods as nonviable "bits of coagulated protoplasm." They are apparently neither nuclei nor precursors of the hypothetical "virus phase."

THE IMPROVEMENT OF MILK SUPPLIES IN THE UNITED STATES

The response of the American people to the propaganda for the liberal use of milk may be measured by the fact that its use is continually increasing. Our present average national consumption amounts to approximately 55 gallons per person yearly, or not quite a pint daily. It is stated¹ that in some parts of the United States, particularly in the larger cities, this average is maintained and even occasionally exceeded, but in too many places it is not reached at all, so that an utterly inadequate amount of milk and dairy products is used for family consumption among a vast portion of our population. There may be some debate as to the optimal consumption, especially for the different age groups. The uncertainty has been reflected in occasional discussions among physicians. A few persons are unable to consume milk because they are allergically hypersensitive to some ingredient of it. Almost every one, however, is today convinced of the importance of pure milk supplies. As Tobey¹ has remarked, for years health officials and physicians have been teaching the public to demand pure milk. As a result of this entirely proper instruction, the people want clean and safe milk, a product which the dairy industry has been and is anxious to give them. Obviously, it does not pay to produce milk which can and does spread disease. One epidemic traced to a dairy farm or milk route means that the farmer or dealer goes out of business, and he may even be so unfortunate as to make himself liable to criminal prosecution or to civil suits for damages. The campaign for purer milk has thus been projected to inspire confidence in the cleanliness and safety of dairy products, it is an effort to "improve the almost perfect food." Some indication of how well this has succeeded is afforded by a recent report of a typical Eastern city of less than 200,000 inhabitants. The results of official laboratory examinations of four unbroken samples of milk taken from each producer during the first three months of

² Palmer W L and Heinz T E. Mechanism of Pain in Gastric and Duodenal Ulcers. Arch Int Med 53: 269 (Feb.) 1934.

¹ Tobey J A. Milk the Indispensable Food. Milwaukee: Olsen Publishing Company, 1933.

the year show that of the forty-three firms furnishing pasteurized milk no less than thirty-two supplied milk with a bacterial count of less than 5,000, only six exceeded a count of 10,000, and only a single dairy failed to show a count of less than 50,000. Not a single specimen of milk, whether pasteurized or supplied by thirty producers of raw milk from tuberculin tested cattle, had a butter-fat content of less than 3.25 per cent. Of the entire group of seventy-two producers, fifty-nine supplied milk exhibiting a butter-fat content of 4 per cent or over. What a contrast to the days of watered and otherwise adulterated milk! What a demonstration of the power of public opinion directed and reinforced by the leadership of preventive medicine and public health!

THE CLEVELAND SESSION

Schedule for Radio Broadcasts

MONDAY, JUNE 11

WGAR The New Deal in Appendicitis by John O. Bower M.D., 9 45 10 a. m. Eastern standard time

WHK The Present Status of Health Examinations by Wingate M. Johnson M.D. 4 4 15 p. m.

WTAM (ABC) Common Colds, by Wilson G. Smillie M.D. 5 5 15 p. m.

TUESDAY, JUNE 12

WHK (CBS) The Family Doctor by Nathan B. Van Etten M.D. 9 45 10 a. m.

WGAR Simple Cheap Happy by Thurnian B. Rice M.D. 10 10 15 a. m.

WTAM New Diabetes for Old by Priscilla White M.D. 4 45 5 p. m.

WEDNESDAY, JUNE 13

WGAR Blood Building Foods by James S. McLester M.D. 9 45 10 a. m.

WHK Cancer Is Curable by Max Cutler M.D., 4 4 15 p. m.

WTAM (NBC) Your Doctor by Walter L. Biering M.D. 4 45 5 p. m.

THURSDAY, JUNE 14

WGAR Relieving Hay Fever and Asthma by George W. Waldbott M.D. 10 10 15 a. m.

WHK (CBS) Medicine Marching Forward by Morris Fishbein M.D. 3 3 15 p. m.

WTAM Convention Highlights by Morris Fishbein M.D. 5 15 5 30 p. m.

MEDICAL BROADCASTS

National Broadcasting Company

The American Medical Association broadcasts on a coast-to-coast network each Monday afternoon. The talk on June 11 will be broadcast from Cleveland at 5 o'clock Eastern standard time, and is entitled Common Colds, by Wilson G. Smillie, M.D.

The National Broadcasting Company talks will be discontinued for the summer with the talk from Cleveland on June 11.

Columbia Broadcasting System

The Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45 Central daylight saving time. The June 14 broadcast will be from Cleveland from 4 to 4 15 p. m., Eastern standard time. The next three broadcasts will be as follows:

June 14 Medicine Marching Forward Morris Fishbein M.D. (from Cleveland)
June 21 Mischievous Misconceptions W. W. Bauer M.D.
June 28 Motor Touring and Camping W. W. Bauer M.D.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Poliomyelitis Prevalent—All activities other than routine school work were forbidden in the elementary schools of Los Angeles, June 1, because of the spread of infantile paralysis, according to the *Chicago Tribune*. During May in Los Angeles County 259 cases of the disease were reported.

New Health Officers—Dr. Harry N. Hensler has been appointed health officer of San Anselmo, succeeding Dr. Lloyd G. Tyler. The city health department of Menlo Park has been taken over under contract by the San Mateo County Health Department, of which Dr. Harold E. Morrison is health officer. Mr. Edward H. Hart has served as health officer of Menlo Park. Dr. Raymond R. Scott has been named health officer of Selma, succeeding Dr. Dietrich V. Wiebe and Dr. Aghavan A. Shaghoeian of Daly City, to succeed Ferdinand P. Callen, D.D.S.

COLORADO

Fifty Years in Practice—A banquet was held by the Medical Society of the City and County of Denver, May 22, in honor of twenty-one members who have completed fifty or more years in the practice of medicine. The sixteen guests of honor who were able to attend were introduced following the dinner and presented with a certificate. The following are the physicians honored, with their dates of graduation:

William Cotterell Bane	1879	Herbert W. McLauthlin	1882
Mary E. Bates	1881	Francis H. McNaught	1878
George Beggs Crews	1883	George W. Miel	1883
Howard Roxboro Elliot	1881	Howell T. Fershing	1883
Josiah N. Hall	1882	David A. Strickler	1881
Clinton G. Hickey	1884	Charles B. Van Zant	1884
Edward Jackson	1878	Herbert B. Whitney	1881
Robert Levy	1884	Horace G. Wetherill	1878
Hugh F. Lorimer	1883	Newton Wiest	1884
George N. Macomber	1878	Andrew K. Worthington	1883
Samuel R. McElvey	1884		

FLORIDA

Society News—The health department of Lakeland is conducting an immunization clinic for typhoid and diphtheria for persons unable to pay for treatment. Dr. Robert M. Faver, Miami, addressed the Dade County Medical Society in Huntington, May 4, on "Diagnosis and Treatment of Glaucoma," and Dr. Ralph A. Gowdy, Miami, "Different Types of Surgery for Peptic Ulcer."

State Medical Election—Dr. Homer L. Pearson Jr., Miami, was inducted into the presidency of the Florida Medical Association at its annual meeting, May 2. Dr. Herbert L. Bryans, Pensacola, was chosen president-elect, and Dr. Shaler A. Richardson, Jacksonville, reelected secretary. Stewart G. Thompson, D.P.H., was appointed business manager, a newly created position. The next annual session will be held in Ocala in 1935.

A Short Graduate Course for Practitioners—The Florida Medical Association is sponsoring a short course at the University of Florida, June 25-30, the purpose of which is to present to Florida physicians the latest discoveries in medical science. The state board of health plans to set up a model laboratory such as would be required by physicians in general practice, with a technician in charge. There will be exhibits by the Florida Dermatological Association and the Florida Roentgenological Association. Participating in the course will be the following physicians:

William Wayne Babcock	professor of surgery	Temple University
School of Medicine	Philadelphia	
Horton R. Casparis	professor of pediatrics	Vanderbilt University
School of Medicine	Nashville	
Chevalier Jackson	professor of bronchoscopy and esophagoscopy	Temple University
School of Medicine		
Edward L. King	professor of obstetrics	Tulane University of Louisiana
School of Medicine	New Orleans	
John A. Kolmer	professor of medicine	Temple University
School of Medicine		
Oliver C. Wenger	surgeon	U. S. Public Health Service
National Park	Ark.	

The registration fee for the course is \$5. Further information will be supplied by the secretary of short courses and institutes, General Extension Division, University of Florida, Gainesville.

GEORGIA

Personal—Dr Charles L Ridley has been appointed superintendent of the Macon Hospital—The Georgia Medical Society held a banquet for Dr Eugene R Corson Savannah, April 30, to honor him as the oldest physician in years of practice in the society, Dr Corson has practiced more than fifty years Dr Henry L Lexington, president of the society, presided at the banquet

Dr Redfearn Awarded Prize—Dr James A Redfearn, Albany, has been awarded the Lamartine Griffin Hardman Cup, it was announced at the annual meeting of the Medical Association of Georgia in Augusta, recently, for his "outstanding work in bringing about the malaria control program in Dougherty County" Dr Redfearn is the second physician to have his name inscribed on the cup, which was presented to the Georgia Medical Association by Dr Hardman when he was governor of the state (THE JOURNAL, July 8, p 146) The cup, which is kept on display at the capitol in Atlanta, marks a contribution to the field of public health or discovery in medicine

ILLINOIS

Society News—The St Clair County Medical Society was addressed in East St Louis May 3, by Dr Arthur H Deppe on "Reflexes, the Method of Elicitation and Their Interpretation," and in Belleville, April 2, by Dr Duff Allen, St Louis, on "Thyroidectomy and Treatment of Heart Disease" Dr John Albert Key, St Louis, addressed the society, April 5, on "Certain Fractures Which Involve Joints"—At a meeting of the Shelby County Medical Society at Shelbyville April 27 Dr Clarence F G Brown Chicago discussed "Treatment of Pneumonia" and "Clinical Aspects of Peptic Ulcer"

Chicago

Lectures at Century of Progress—Six lectures will be given each week in the South Room, Hall of Science, at a Century of Progress by members of the Chicago Medical Society Dr Austin A Hayden gave the introductory address, May 28, on "Conservation of Hearing" Other speakers during the week were Drs Leon Unger, "Hay Fever", Frank F Maple, "Prenatal Care" Hilmer William Elghammer, "Rheumatic Infection in Children" Laurence E Hines, "Heart Disease," and Gilbert Fitz-Patrick, "Is Cancer Curable?"

Fifteen Years for Passing Counterfeit Money—Valentine G Burtan, M.D., New York, and a native of Russia was sentenced, May 25, to fifteen years in Leavenworth penitentiary and fined \$5,000 on charges of possession and distribution of counterfeit money He was found guilty in federal court in Chicago, May 4 Motion for a new trial was overruled Henry Dechow, alias Count Enrique von Buelow the principal witness in the case, was, according to the newspaper reports formerly one of Burtan's patients to whom Burtan is said to have proposed the disposal of bills which he had received from a gangster patient About \$25,500 of this counterfeit money was passed through Chicago banks Burtan admitted accompanying Dechow to Mexico City in 1932 According to Dechow the object of the trip was to pass counterfeit money but Dr Burtan stated it was to sell munitions to the Mexican government Records of the American Medical Association show a Vladimir Gregory Burtan born in Odessa, Russia, in 1897 He graduated from University and Bellevue Hospital Medical College, New York in 1923, and served as an intern at French Hospital, New York until 1924, since which time he has been practicing internal medicine in New York City

IOWA

Society News—Dr William J Mayo, Rochester, instead of Dr Charles H Mayo addressed the Linn County Medical Society, June 7, on "Some of the Physical Aspects of Water," and Dr James T Priestley Jr, Rochester on "Current Conception of Nephrolithiasis"—The Four County District Medical Society was addressed in Cherokee May 22 among others, by Dr Joseph E Dvorak Sioux City, on strabismus and its treatment, and Dr Robert B Armstrong, Idagrove toxemia in pregnancy

State Medical Election—Dr Thomas A Burcham Des Moines was chosen president-elect of the Iowa State Medical Society at its annual meeting in Des Moines May 11 Dr Gordon F Harkness, Davenport was installed as president Vice presidents are Drs Frank B Dorsey, Keokuk, and James C Hill, Newton, Dr Robert Parker Des Moines was reelected

secretary Davenport was selected for the annual session in 1935 It was recommended at this meeting that the state legislature enact a basic science law

Twenty-Eight Typhoid Cases Traced to Carrier—Twenty-nine cases of typhoid were reported in Newark township, Webster County, from 1905 to 1933, in all but one of which it was possible to trace the source of infection to a woman carrier This was revealed in a recently completed typhoid survey of the township, the state medical journal states Five deaths occurred during this period Laboratory analysis revealed typhoid bacilli present in the specimen of a woman aged 65, who, with her husband, had acquired typhoid in Oklahoma in 1901 Six of the cases occurred among the woman's relatives and four among farm hands who were employed at different times on her husband's farm Six persons developed typhoid following church or school picnics at which the woman helped with the preparation and serving of food In addition, six patients represented secondary cases occurring in various homes, making the total number of twenty-eight In 1927, the state medical journal reports, it was suspected that this woman was a carrier, but laboratory specimens failed to demonstrate the fact

KANSAS

State Medical Election—Dr John F Hassig, Kansas City, for many years secretary of the Kansas Medical Society was chosen president-elect at the society's recent annual meeting in Wichita Dr William F Bowen, Topeka, will retire from the presidency, December 31 Dr Howard L Snyder, Winfield was elected vice president, effective in January and Dr Harry L Chambers, Lawrence, was named secretary Dr George M Gray, Kansas City, was reelected treasurer The next annual meeting will be held in Salina May 8-10 1935 The house of delegates unanimously voted to employ a full time executive secretary and editor with offices in Topeka and referred the matter to a committee of seven who shall make a selection about November 1

LOUISIANA

Personal—The cross of a chevalier of the French Legion of Honor was recently conferred on Dr Amedee Granger professor of radiology, Louisiana State University Medical Center, New Orleans

Society News—Ernest C Faust, Ph.D. professor of parasitology Tulane University of Louisiana School of Medicine, New Orleans, was elected vice president of the New Orleans Academy of Sciences recently—Speakers before the Orleans Parish Medical Society in New Orleans May 14, were Drs Howard R Mahorner on 'Jaundice Associated with Hyperthyroidism' John T Sanders "Treatment of Acute Pelvic Infection with Special Reference to the Elliott Treatment" and Upton W Giles, 'Rational Treatment of Diabetes Mellitus'—Dr William T Pride Memphis addressed the New Orleans Gynecological and Obstetrical Society, April 19, on 'Analgesia and Anesthesia in Obstetrics'

MASSACHUSETTS

Medal to Dr Conant—James Bryant Conant, Ph.D., Shelton Emery professor of organic chemistry and chairman of the department, Harvard University has been awarded the annual medal of the American Institute of Chemists for "outstanding service to chemistry" According to the announcement, 'Dr Conant has done notable work in establishing the chemical structure of many complicated organic compounds, including among others, hemoglobin of the blood substance, chlorophyll, the green coloring matter found in plant life and a number of other coloring substances occurring in flowers and feathers The medal was presented to Dr Conant May 21 In 1932 Dr Conant was awarded the Chandler Medal by Columbia University and the William H Nichols Medal by the New York Section of the American Chemical Society

Survey of Internship Facilities—The committee on medical education and medical diplomas of the Massachusetts Medical Society recently completed a preliminary survey of intern training in the state to ascertain the internships available how they are filled and how they may be improved In 1933 thirty-one Massachusetts hospitals offered this training to 312 graduate medical students the majority of whom were from Tufts, Harvard and Boston University medical schools In addition thirty-six other American medical institutions were represented two Canadian institutions and three foreign schools Ten women interns were enrolled In a consideration of the intellectual level, it was stated that half the interns graduated in

the upper third of the scholastic classes, while only one fifth graduated in the lower third. Of the three internships that are generally offered, rotating services are much more frequently presented than the straight "medical or surgical." Great variability in the number of hospital beds for each intern was apparent in the survey, several hospitals being so understaffed that interns are expected to cover more than fifty beds per man while two institutions are so arranged that they have an intern for each eleven beds.

MINNESOTA

Personal—Dr Frederick A Erb, Minneapolis was recently reelected president of the Hennepin County Tuberculosis Association. —Dr Lawrence J Leonard Minneapolis has been admitted to the bar in Minnesota, according to the *Journal-Lancet*.

Named Director of Indian Service—Dr Langdon R White of the U S Public Health Service has been named medical director for the Indian service of Minnesota, Wisconsin, Michigan, Iowa and North and South Dakota. His headquarters will be in Minneapolis.

Program on Internal Medicine—The sixteenth semiannual session of the Minnesota Society of Internal Medicine was held at Rochester, April 23. Included among the speakers were the following physicians:

George E Brown Rochester Extracts of Skeletal Muscle in the Treatment of Intermittent Claudication and Other Types of Muscular Pain
Richard M Johnson and Hobart A Reimann Minneapolis Calcium Balance and Plasma Protein Studies in Myeloma
Frederick A Willis and Harry L Smith Rochester, Factors Concerned in the Production of Cardiac Hypertrophy
Hugh O Altow Minneapolis Hepatic and Splenic Enlargement in Renal Amyloidosis
Bayard T Horton Rochester Diagnosis of Congenital Arteriovenous Aneurysm
Cecil J Watson Minneapolis Porphyrin Excretion in Certain Anemias

MISSOURI

State Medical Election—Dr Caius T Ryland Lexington, was installed as president of the Missouri State Medical Association at its annual meeting May 9. Dr Edwin Lee Miller, Kansas City, was chosen president-elect, and Dr Edward J Goodwin, St Louis was reelected secretary. The next annual session will be held at Excelsior Springs.

NEW YORK

Stop Tuberculin Tests to Avert Milk Shortage—The testing of dairy cattle for tuberculosis was suspended, June 1 in an effort to prevent a shortage of milk in the state this summer it was reported. It was pointed out that 45,000 tuberculous cows have been killed in the state since February 1, for which farmers have received nearly \$2,000,000. About one half of this amount is paid by the federal government. Unusual weather conditions, resulting in extremely dry pastures make it evident "that there is a possibility of a severe shortage of milk within a comparatively short time." A protest was sent to the state commissioner of agriculture by the Hospital Association of New York State, contending that the order is dangerous to the public and especially to hospital patients.

Epidemic of Vincent's Angina—More than 500 cases of Vincent's angina have occurred during the past three months in the village of Dansville, and cases have also been found in Geneseo, Livonia and rural areas in Livingston County. According to the state health department the majority of cases have been typical clinically, the disease being characterized by fairly extensive ulceration of the oral or pharyngeal mucous membrane, sometimes accompanied by fever and constitutional symptoms. A few patients have been seen with symptoms like those of bronchitis. About two thirds of those attacked are school children. The Livingston County laboratory has records of positive throat smears from 443 persons all of whom are said to have the disease. The local health officer has taken active steps toward the control of the outbreak and has informed the public regarding it through the newspapers. The village board of Dansville has appropriated funds for neocarsphenamine to be used in treating patients who are unable to pay for this drug.

New York City

Personal—Dr Thomas A McGoldrick, a police surgeon since 1907, was appointed acting chief surgeon of the police department, May 3, to succeed the late Dr Daniel J Donovan. —Dr Charles Gordon Heyd has been appointed professor of clinical surgery and executive officer of the department of sur-

gery at Columbia University College of Physicians and Surgeons. —Dr Oscar M Schloss has resigned as full time professor of pediatrics at Cornell University Medical School and pediatrician in chief of New York Hospital but will continue as professor of clinical pediatrics and attending pediatrician to the hospital. —Dr Haven Emerson has recently been made an honorary fellow of the Royal Sanitary Institute of England. —Dr Isaac Ogden Woodruff, professor of clinical medicine, Columbia University College of Physicians and Surgeons, was elected president of the New York Tuberculosis and Health Association, May 22, succeeding the late Dr Linsly R Williams. —Dr Thomas Howell has been appointed superintendent of the New York Hospital-Cornell Medical Center to succeed John R Howard Jr., resigned. —Dr David Warshaw has been appointed associate surgeon of Trinity Hospital Brooklyn.

Hospital News—Dr James W Smith, assistant professor of ophthalmology, New York Post-Graduate Medical School, delivered a lecture on "Eye Diseases of Interest to the General Practitioner" at the West Side Hospital and Dispensary, April 12. —Beth-El Hospital, Brooklyn, held a three-day seminar, May 8-10, to show in condensed form work done within the institution by its attending staff, combined with summaries of recent advances in medicine and surgery by the consulting staff. Dr Maurice J Dattelbaum was chairman of the committee which planned the innovation. —St Joseph's Hospital, Yonkers, recently opened a new addition with a capacity of eighty-five beds. —A committee has been appointed by Dr Sigismund S Goldwater, commissioner of hospitals, to make a complete survey of the city psychiatric service. Dr Charles A McKendree is chairman and members are Drs Frederick Tilney, Henry A Riley, Charles Diller Ryan, Israel Strauss, Mortimer W Raynor and Clarence O Cheney. —Mount Sinai Hospital has begun publication of a journal to be devoted principally to case reports. In addition, special lectures given at the hospital will be printed. Dr Joseph H Globus is editor of the new publication, which will be known as the *Journal of the Mount Sinai Hospital*.

OHIO

Society News—Dr Henry B Freiburg, Cincinnati, addressed the Clinton County Medical Society, May 1, on prostatic resection. —Dr Arthur S Jones, Huntington, addressed the Washington County Medical Society, Marietta, May 9 on "Peripheral Nerve Injuries." —Dr J Isfred Hofbauer, Cincinnati, addressed the Mason County Medical Society, May 9 on "Advances in Early Diagnosis and Pathogenesis of Uterine Carcinoma." —Dr Martin H Fischer, Cincinnati, addressed the annual meeting of the Montgomery County Medical Society Dayton, June 1, on "Art and Practice."

PENNSYLVANIA

Clinical Demonstration of Cancer—The Pittsburgh Skin and Cancer Foundation presented its second annual clinical demonstration at its dispensary, May 23. About eighty patients were exhibited with carcinoma of the skin, mucous membrane and the mammary glands and with lymphoblastomas, bone tumors, tuberculosis of the skin and numerous common skin diseases. Four papers were presented in the evening. Drs Edwin P Buchanan, on carcinoma of the breast, Joseph A Perrone, carcinoma of the larynx, Forrest L Schumacher, recent advances in x-rays, and George J Kastlin, adjuvant medical treatment in carcinoma.

Philadelphia

Drawings Depict Hospital Activities—Designed to serve as a record for future generations, the hospital routine of the present time has been arranged in pictorial form, according to *Hospital Management*. The activities of Hahnemann Hospital have been studied by the artist and have been set down in oil, charcoal, wash drawings and water colors. Forty sketches complete the series and will be displayed at the Century of Progress. Later they will be returned to the hospital. Scenes are being made from all floors of the hospital, the laundry, kitchens, engine room, morgue and all clinics so that a complete picture of every activity and every phase of hospital life will be a matter of record.

Second Professorship of Medicine Created—The executive board of trustees of the University of Pennsylvania voted, May 25, to establish a second professorship of medicine at the university, the first time since the founding of the school of medicine 169 years ago that a provision has been made for more than one professor of medicine. Dr Oliver H Perry Pepper professor of clinical medicine, was appointed to fill the

new position Dr Pepper graduated from the school of medicine in 1908 and since that time has been affiliated with it in various teaching positions. He is the third member of his family to be elected professor of medicine at the university. His grandfather, Dr William Pepper, held the position from 1860 to 1864, and his father, Dr William Pepper, who died in 1898, was also professor of medicine for a number of years as well as provost of the university. At this meeting of the board, the term of Dr Alfred Stengel, present professor of medicine, was extended for three more years, although Dr Stengel has reached the age of retirement after forty-one years on the medical faculty. He will continue also as vice president of the university in charge of medical affairs, which position he has held since 1931.

SOUTH DAKOTA

Personal—Dr Emilie E Rauch, Belvidere, has been appointed health officer of Jackson and Washabaugh counties.—Dr Raymond P Frink, Wagner, has been appointed physician to Indians on the reservation near Greenwood, during an illness of Dr Andrew Ritan.

State Medical Election—Dr William G Magee, Watertown, was installed as president of the South Dakota State Medical Association at its annual meeting, May 16, and Dr Albert S Rider, Flandreau, named president-elect. Dr John F D Cook, Langford, was reelected secretary. The next annual session will be held at Pierre.

Society News—Drs Paul R Billingsley, Sioux Falls, and Walter H Karlins, Webster, addressed the Whetstone Valley District Medical Society in March on "Endometriosis" and "Functional Treatment of Fractures," respectively.—Dr Porter P Vinson, Rochester, Minn., addressed the Seventh District Medical Society, Sioux Falls, May 8, on "Value of Bronchoscopy in Diagnosis and Treatment of Pulmonary Diseases."

VIRGINIA

Society News—Dr Henry B Mulholland, University, addressed the Bath-Alleghany County Medical Society, recently, on "Newer Treatment of Diabetes Mellitus."—Drs Edward C Joyner and William T Gay, Suffolk, addressed the Second District Medical Association in Suffolk, April 18, on "Skull Fracture" and "Traumatic Rupture of the Kidney," respectively.—At a meeting of the South Piedmont Medical Association in South Boston, April 17, the general topic of discussion was endocrinology. Among speakers were Drs James Edwin Wood Jr, University, Regina C Beck, Manfred Call III, and Thomas F Wheelon, Richmond, and Jesse M Shackelford, Martinsville.—Drs James C Flippin and James R Cash presented a joint paper before the Richmond Academy of Medicine, April 24, on "Autopsy Findings in Certain Cases of Jaundice," John H Neff, "Renal Calculi," and Sydney W Britton "Physiology of the Suprarenal Gland." Dr Flippin also addressed the North Virginia Medical Society at Hunt Hill, April 26, on "Clinical Diagnosis of Digestive Disorders."

WASHINGTON

Graduate Lectures at State University—The eighteenth annual course of graduate lectures and clinics offered by the University of Washington, Seattle, will be presented July 16-20. Lecturers will be Drs Edmund Andrews, Chicago, on surgical subjects, Jay Arthur Myers, Minneapolis, tuberculosis, Harold E Robertson, Rochester, Minn., pathology, and Francis Scott Smyth, San Francisco, pediatrics.

WISCONSIN

Society News—Dr Robert L Eagan, LaCrosse, was elected president of the Seventh District Medical Society in Whitehall, May 16, speakers included Drs James T Priestley Jr and Joseph G Mayo, Rochester, Minn., on "Present-Day Management of Prostatic Obstruction" and "Secondary Anemias," respectively. Dr and Mrs William J Mayo were guests of honor at the meeting.—Dr Horace Kent Tenney Jr, Madison, addressed the Brown-Kewaunee-Door County Medical Society, Green Bay, recently, on empyema.—Drs Charles W Mayo and Edward H Rynearson, Rochester, Minn., addressed the Fond du Lac County Medical Society, Fond du Lac, March 14, on "Newer Surgical Treatment of the Thyroid Gland" and "Newer Methods of Medical Treatment of the Thyroid Gland," respectively.—Dr George W Hall, Chicago, addressed the Outagamie County Medical Society, Appleton, April 3, on "Newer Things in Neurology."—At a meeting of the Racine County Medical Society, Racine, March 15, Dr Edmund H Mensing, Milwaukee, discussed intestinal obstruction.

GENERAL

Honorary Membership in American Urological Association—At the annual session of the American Urological Association held in Atlantic City, Mr Fred Wappler, New York, son of the late Reinhold Wappler, was made an honorary member of the association. Because of his contributions to urology, a similar honor was bestowed on the father.

Warning Against Unauthorized Salesman—A Texas physician reports that his office bought two office coats from a salesman giving the name of H A Wilson and purporting to represent Durastyle Apron and Uniform Company, St. Louis, March 14. When the order was not delivered on the date promised, inquiry was made of the firm, which replied that Mr Wilson had left its employ some time previously and that they had not received such an order. The man carried sample books and order blanks of this firm.

Dr Cannon Receives Award—Dr Walter B Cannon, George Higginson professor of physiology, Harvard University Medical School, Boston, was presented with a gold medal of the National Institute of Social Sciences at the institute's annual dinner, May 10, "in recognition of distinguished services for the benefit of mankind through contributions to medical science and education." The presentation speech was made by Dr John A Hartwell, director of the New York Academy of Medicine. A graduate of Harvard, Dr Cannon is a member of several scientific societies. He is the author of many contributions to medical literature.

Scientists Honored—Gold medals were presented by the American Institute at a meeting in New York, May 3, to Oscar Riddle, Ph.D., investigator, Carnegie Institution Station for Experimental Evolution, at Cold Spring Harbor, L I, for his endocrine research, and to Elmer V McCollum, Ph.D., professor of biochemistry, Johns Hopkins University School of Hygiene and Public Health, Baltimore, in recognition of his work on nutrition. Henry C Sherman, Ph.D., professor of chemistry, Columbia University, New York, made the presentation to Dr McCollum and Allan Winter Rowe, Ph.D., professor of chemistry, Boston University School of Medicine, Boston, to Dr Riddle.

Yellow Fever Volunteer Dies—Albert W C Covington, staff sergeant, U S Army, retired, one of the volunteers in the yellow fever experiment in Cuba in 1900-1902, died in the Canal Zone, April 20. Sergeant Covington, following his inoculation, fell ill, Oct 19, 1901, with a typical case of yellow fever but recovered completely and returned to duty. Born in Laurinburg, N C, July 1, 1878, he served almost continuously in the regular army from his enlistment in 1899 until his retirement in 1920. With the death of Covington, there remain about thirteen survivors of the experiment, which was directed by Major Walter Reed. In 1929, Congress authorized the presentation of gold medals and a monthly pension of \$125 to these volunteers.

Pacific Northwest Medical Association—The tentative program of the annual session of the Pacific Northwest Medical Association, to be held in Salt Lake City, June 21-23, includes the following speakers, each of whom will make several addresses:

Dr John S Lundy, Rochester, Minn., obstetrics and anesthetics
Dr Ray M Balyeat, Oklahoma City, migraine, seasonal hay fever and asthma and food sensitization
Dr Joseph L Miller, Chicago, chronic rheumatism, undulant fever and anemia
Dr Frank Hinman, San Francisco, urinary infection, prostatism, oliguria and anuria
Dr Alton Ochsner, New Orleans, appendicitis, ileus and cranio-cerebral injuries
Dr William C MacCarty, Rochester, Minn., cancer, surgical pathology of the stomach and duodenum, and ovarian cysts
Chauncey D Leake, Ph.D., San Francisco, depressant drugs, drugs for diagnostic tests and chemotherapy of syphilis and amebiasis.

Medical Bills in Congress—Changes in Status S 433 has been favorably reported to the Senate, directing the retirement of acting assistant surgeons of the United States Navy at the age of 64 years (S Rept 1187). S 2974 has passed the House, amending the longshoremen's and harbor workers' compensation act. Among other things, the bill proposes to authorize the deputy commissioner to suspend the payment of compensation during any period in which the employee unreasonably refuses to submit to medical or surgical treatment. S 1587 has been favorably reported to the House, amending an act entitled "An act to recognize the high public service rendered by Maj. Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever," by including Roger P Ames among those honored by the act (H Rept 1757).

Society News—Dr Herbert E. Randall, Flint, Mich., was elected president of the Northern Tri-State Medical Association at its annual convention in Flint, recently. The next annual session will be held in Lima, Ohio. Indiana is the third state included in the tristate group. The American Association of the History of Medicine will meet at the Hotel Carter, Cleveland, June 11. Dr Edward J. G. Beardsley, Philadelphia, is secretary. The Mississippi Valley Conference on Tuberculosis and the Mississippi Valley Sanatorium Association will be held at Cedar Rapids, Iowa, September 27-29, with headquarters at the Hotel Montrose. Dr Robert C. Bryan, Richmond, Va., was inducted into the presidency of the American Association of Genito-Urinary Surgeons at its annual session May 16, and Dr James D. Barney, Boston, was chosen president elect. Dr Henry L. Sanford, Cleveland, was reelected secretary.

The Safety Program in CWA Project—Preliminary reports on the safety program in connection with the Civil Works Administration indicate that only half the expected number of deaths from accidents occurred during the period of the projects. As many as 800 deaths were anticipated among the 4,000,000 men employed, but reports indicated that the number would be about 400. The chief cause of fatal injuries was falling objects, which accounted for 113 deaths. Other important causes were vehicles, chiefly trucks, 98 deaths, falls 58 and explosives, 11. State safety directors were appointed, who in turn appointed county safety directors, incidentally taking the campaign of instruction, inspection and first aid to areas which would normally not have had any contact with the safety movement for many years. The American Red Cross cooperated in training 60,000 workers in first aid, between 80,000 and 90,000 first aid kits were available and about 80,000 pairs of goggles were used on the projects.

Changes in Status of Licensure—The Iowa State Department of Health reports that

The license of Dr. Clarence Henry Hanson, Bode was reinstated March 13.

The Massachusetts Board of Registration in Medicine reports the following:

Dr. Percy W. Carr, Boston, license revoked for his conviction in court for administering medicine to produce an abortion. Dr. Carr has been committed to the Massachusetts State Prison (THE JOURNAL, May 5 p. 1505).

The Minnesota State Board of Medical Examiners reports the following:

Dr. Arthur W. Eckstein, formerly of Mankato, license revoked May 8 following his conviction March 31 of the crime of abortion. Dr. Eckstein is serving two years in the state prison at Stillwater.

Dr. Milton G. Brown, Dakota, license revoked, May 8 for habitual use of morphine. Dr. Brown had been before the board on two previous occasions for the same offense.

The Indiana State Board of Medical Registration and Examination reports the following:

Dr. John A. Newhouse, license revoked March 30 for his conviction in the U. S. Iowa District Court for violation of the Harrison Drug Act, fined \$500 and costs. Convicted in April 1933 and deported to Canada June 25, 1933.

CANADA

New Dean at Laval University—Dr. P. Calte Dagneau, professor of clinical surgery, Laval University Faculty of Medicine, Quebec, has been appointed dean to succeed the late Dr. J. M. Arthur Rousseau. Dr. Dagneau was chief surgeon at the Hotel-Dieu from 1914 to 1927 when he became chief surgeon at St. Sacrament Hospital, Quebec. He was graduated from Laval in 1901.

Hospital Burned—Parry Sound General Hospital, Parry Sound, Ont., on Georgian Bay, a frame structure built about fifty years ago, was burned beyond repair April 25. Twenty-six patients were rescued from the burning building and valuable hospital equipment was saved. It was expected that patients would be transferred to Bracebridge Hospital, twenty-five miles away, but they were temporarily cared for in an abandoned apartment building in Parry Sound.

Dr. Banting is Knighted—On the sixty-ninth birthday of King George of England, June 3, Frederick Grant Banting, since 1923 professor of medical research, University of Toronto School of Medicine, Toronto, was made a knight, in recognition of his discovery of insulin. Born in 1892 in Alliston, Ont., Dr. Banting graduated from the University of Toronto School of Medicine in 1916. He practiced until 1921 when he commenced his research on the internal secretion of the pancreas. During the year 1920-1921 he was affiliated with Western University, Ontario, as part time assistant in physiology. He was awarded the Nobel Prize in 1923 and the Scott Medal in 1924.

Foreign Letters

LONDON

(From Our Regular Correspondent)

May 12, 1934

So-Called Mucous Colitis

In a discussion at the Royal Society of Medicine on the treatment of mucous colitis, Dr. A. F. Hurst, senior physician to Guy's Hospital, showed that the term was misleading and that specialism in therapeutics had dangers even greater than those in other branches of medicine. An expert in any line of treatment was tempted to accept the diagnosis already made in cases sent to him and to apply treatment without sufficiently full consideration. Thus, if a patient diagnosed as suffering from mucous colitis was sent to a bacteriologist he would be treated with vaccines if he was sent to a spa, he would be treated with Plombieres douches, if sent to an electrotherapist, diathermy would be used. Yet a fuller investigation might show that the so-called mucous colitis was the result of achlorhydria and could be rapidly cured by gastric lavage or administration of hydrochloric acid, or that it might be the first manifestation of carcinoma of the pelvic colon, and while useless treatment was being applied pass into the stage of inoperability. Dr. Hurst had seen many examples of these mistakes. When invited to open the discussion he was inclined to reply, "There is no such thing as mucous colitis, so I cannot open a discussion on its treatment." But then he thought that he might explain why he objected to the diagnosis and at the same time discuss what disorders of the colon were suitable for physical therapy. Mucous colitis meant inflammation of the colon associated with the passage of excess of mucus. It was therefore necessary to consider in what conditions an excess of mucus was passed. The secretion was increased in response to mechanical and chemical irritants. Hard feces in the pelvic colon and rectum acted as mechanical irritants. Consequently the dry scybala passed in dyschezia (a common form of constipation) were covered with mucus that contains no inflammatory products, such as leukocytes or red corpuscles. Endoscopy showed a perfectly healthy mucous membrane. Therefore the diagnosis of mucous colitis should not be made.

The most common chemical irritants of the colon were purgatives. They produced an excess of mucus but again no inflammatory products. The mucus protected the colon so efficiently that colitis resulted only when large doses of purgatives were taken for long periods. In such case the diarrhea induced by the purgatives persisted after they were discontinued. Therefore excess of mucus with soft or liquid feces in a patient taking aperients did not justify the diagnosis of mucous colitis.

Another cause of chemical irritation of the colonic mucous membrane was the use of irritating suppositories, enemas and douches. Glycerin suppositories and enemas, though useful under exceptional conditions always called forth an abundant secretion of mucus, without, however, any evidence of proctitis. Soap and all kinds of medicated enemas and douches caused similar but less intense irritation. So did most natural waters used for douching at spas. Physiologic solution of sodium chloride was almost the only fluid that did not stimulate the secretion of mucus. In what the Americans call "colon laundries" where intestinal lavage was practiced, reports such as this were made. "The first twelve pints brought away loose feces but no mucus but after that a large quantity of jelly mucus was passed." Here 12 pints of fluid was required to irritate the healthy mucous membrane to secrete mucus. Patients were often diagnosed as suffering from mucous colitis.

although they never passed mucus until irritated by the Plombieres douche. Lastly, when excess of undigested food reached the colon, as in achlorhydric gastritis and in enteritis, the colonic mucous membrane might respond by secreting mucus, although no colitis was present. Indeed, achlorhydric gastritis was the most common of all causes of chronic diarrhea, with excess of mucus.

Only the exceptional cases of true mucous colitis remained, in which liquid stools containing excess of mucus and of leukocytes with sometimes a few red corpuscles were passed, and the sigmoidoscope revealed inflammation. With regard to so-called mucomembranous colitis, the membrane was formed of coagulated mucus and did not contain inflammatory material. The condition should be called mucomembranous colic (as suggested by Ewald) and had many features in common with asthma. It depended on abnormal irritability of the sympathetic nerve supply of the colon and was occasionally allergic, the mucous casts representing the Curschmann spirals of asthmatic patients.

Having done his best to demolish "mucous colitis" as a clinical entity, Dr Hurst turned to the practical question of the many persons with uncomfortable colons, which are organically normal but functionally inefficient. Their condition is often the result of abuse of aperients, occasionally the abuse of enemas. A similar irritable colon is a common sequel of intestinal infections, especially those contracted in the tropics, and may persist for years after the specific dysenteric or other organism has disappeared from the bowel. Mucomembranous colic and the various forms of colon spasm, not secondary to some organic disease, such as ulcerative colitis or diverticulitis, may be included in this group. Such cases are suitable for physical therapy. One form of this, diathermy, Dr Hurst has found of the utmost value in the treatment of the frequent functional disorders of the intestine that result from abnormalities of the anal canal. These include a congenitally small canal, a by no means uncommon cause of constipation; acquired stricture following operations on hemorrhoids, anastomosis with or without hemorrhoids, and anal ulcer and achalasia of the anal sphincter, which Dr Hurst believes to be the cause of megacolon. All these conditions can be relieved and often cured by diathermy, applied by means of a straight electrode, when no obstruction is present and a conical one when there is spasmodic or organic obstruction or achalasia. Such treatment is infinitely preferable to cutting operations.

Auto-intoxication resulting from stasis in the colon, which is regarded as an indication for much treatment of different kinds, Dr Hurst regards as a myth. He holds that untreated constipation may cause local discomfort and be a source of much anxiety to the patient, but that it is rarely the cause of toxemia, as hard dried feces do not undergo bacterial decomposition and, even if they did, the mucous membrane would not absorb anything from them. Only when incompletely digested food is driven by purgatives into the colon, there to undergo putrefaction, does intestinal toxemia result. Apart from the abuse of aperients, the absorption of toxins from putrefaction is not uncommon in the small intestine, especially as the result of achlorhydria, but it is rare in the colon except in specific infections, such as bacillary dysentery.

Chiropody and the Medical Profession

Organizations for instruction in chiropody and the provision of chiropodial treatment have been springing up all over the country. The council of the British Medical Association thought it desirable that the profession should determine its future relation with chiropodists. Inquiry was made of the Incorporated Society of Chiropodists, which was anxious to secure some recognition of its members, as to its attitude toward the following limitations of the field of work of

chiropody: "Chiropody means the treatment of abnormal nails and all superficial excrescences occurring on the feet, such as corns, warts, callosities and bunions. Each of the members undertakes: 1 To confine his practice to the above mentioned conditions. 2 Not even within the above field to operate for (a) any congenital or acquired deformity, (b) any condition requiring either a general or local anesthetic given by injection, (c) any condition involving any structure below the level of the true skin. 3 Not to deal with any patient who at the time is under the care of a physician without his knowledge and consent." The society agreed to this definition and conditions, and accordingly the proposal was made to the council of the British Medical Association that the medical profession should accord a measure of recognition to approved chiropodists and that their names should be included in the National Register of Medical Auxiliaries. It was pointed out that there had been great developments in the field of chiropody and that hospitals and organizations for instruction had sprung up. If some form of recognition of these practices should be accorded, a good opportunity would be given for the control of the craft. Two members of the council took exception to inclusion of bunions as "superficial excrescences." Another member said that the proposal was contradictory to the policy previously sanctioned by the council—that no person who had not passed through the discipline of the medical curriculum could be countenanced as competent to recognize and treat disease. On the other hand, it was pointed out that chiropodists were performing extremely useful work and developing into an important body, and that it would be in the interest of the public that the medical profession should train them along suitable lines. An attempt of the profession to insist that the public could obtain these various auxiliary services only through physicians would be riding for a fall. The council agreed by 16 votes to 12 to recommend to the representative body of the British Medical Association that the medical profession should accord a measure of recognition to approved chiropodists who accepted the definition of their work as given.

New Treatment for Sprains

Professor Leriche of Lyons has contended for some time that in sprains there is no lesion of the ligaments, even when there is an edema and a marked subcutaneous hemorrhagic suffusion. The dominant symptom is the pain caused by the contracture. He affirms also that any sprain can be quickly cured if one allays the pain of the tissues. For this purpose he uses injections of procaine hydrochloride, deep in the painful area. By this method he brings about the disappearance of all the symptoms of sprain within a few hours. In a communication to the Societe de chirurgie he stated that a sprain is essentially a traumatism of the nerves of the ligaments and that these nerve terminals are the point of origin of a reflex acting on the articular trophism and on the vascularization of the motor muscles. He verified the local and the more remote action of the injection of procaine applied to the painful ligaments. He emphasized the need of giving an early injection before the appearance of edema and hydrarthrosis. An application of this method was made at Bordeaux by Courboules, Mandillon and Georget in two cases of traumatic arthritis of the shoulder that developed in young persons. They applied periarticular and intra-articular injections of a 1 per cent solution of procaine hydrochloride, in doses of from 20 to 30 cc. After from three to five injections they noted the total disappearance of all functional symptoms and a complete restoration of articular mobility.

Admission of Wealthy Patients to Charity Hospitals Stopped

The admission of wealthy patients to the *hopitaux de l'Assistance publique* was the subject of an important session of the municipal council of Paris. The grievances of the medical profession were ably supported in vigorous attacks on Mr Mourier, director of the *Assistance publique*, for granting favors to wealthy patients in hospitals under his control. Formerly, consultations and hospitalization were given only to persons registered in a charitable organization. Since the war, conditions have changed. Many persons have had financial losses owing to the devaluation of the franc to 20 per cent of its former value, and that has been further aggravated by the conversion of government bonds and reduction of the interest rate. The economic crisis has hastened this development. On the other hand, the hospitals of the *Assistance publique* have become modernized. Patients now receive excellent care, and the bourgeoisie no longer feels the same repugnance as formerly about applying for treatment, especially since the private hospitals have raised their prices, likewise the physicians' fees have been increased, which is the logical effect of higher rents, higher taxes and the higher cost of living in general. Many salaried persons have not sufficient income to pay the costs of an operation or a long period of sickness in a private hospital. Hence they prefer to seek treatment in the hospitals of the *Assistance publique*. As a result, the administration of the *Assistance publique* has found its expenditures enormously increased. It has built new hospitals. The population of Paris consists at present of more than 20 per cent of foreigners and immigrants from the provinces. To provide funds for the increased expenditures the director of the *Assistance publique* has accepted reasonable fees from persons able to pay who requested consultations or hospitalization, while only persons absolutely without means were treated gratuitously. Every person who receives a salary or who has any other source of income must pay. With a constant increase of expenditures, the fee schedule applicable to persons with funds has been gradually raised. Today the fee for consultation is 6 francs, or \$0.36; the per diem room charge is 36 francs, or \$2.16, in the medical department, and 52 francs or \$3.12, in the surgical department; these prices include the fees of physicians and surgeons, which are apportioned annually by the administration, which takes due account of the fact that their connection with the *hopitaux de l'Assistance publique* increases their prestige among their private clientele. The inevitable result has been that, once the principle of accepting pay for services rendered to the nonindigent was accepted by the city hospitals the well-to-do middle class, and even many persons of considerable wealth, have claimed the right to be treated in these hospitals. The fees asked are much lower than the actual cost of the service rendered. The difference is made up from their own budget, which is a part of the regular budget of the city of Paris. Often eminent physicians and surgeons find themselves deprived of the usual fees of their private clientele, since their wealthy clients prefer to go to the hospital, where they find their regular physician or surgeon who is obliged by the regulations to treat them without exacting any special fee. The director of the *Assistance publique* is not inclined to refuse admittance to wealthy patrons since he increases thereby his receipts. The physicians are protesting vigorously, and rightly so. The controversy flamed up anew at a recent meeting of the municipal council in connection with the vote to be taken on the budget of the *Assistance publique*. Mr Raoul Brandon cited some scandalous facts. Rich patrons pay 6 francs (\$0.36) for a hospital consultation while their luxurious car is parked in a neighboring street. Some patients call an eminent surgeon in private con-

sultation. The surgeon decides that an operation is needed but the patient does not go to the private clinic indicated by the surgeon but gains admittance, at 52 francs (\$3.12) a day, to his department in the hospital, where he is surprised to discover him the day following and is obliged to operate on him. It has been discovered, however, that in certain cases it was the family physician himself who sent his patient to the city hospital, realizing that he would not receive at home the necessary care or be able to provide day and night nurses. The council passed a resolution that no more patients be admitted to the city hospitals without presenting evidence of indigence either a card showing that they are out of work or have social insurance or without presenting their income tax book for inspection, in order that persons who have sufficient funds to pay their physician may be eliminated, an exception being made in emergency cases due to accidents occurring on the public highways. If a charge of fraud can be established, a fine will be imposed representing twenty times the normal fee.

The Government's Attitude Toward Lay Practitioners

According to a recent decree, all persons practicing the art of healing are required to register for incorporation in the new organization of science and industry. Future practice of the healing profession demands the registration of all persons engaged in the treatment of the sick or in health service in general. This is the natural consequence of the decision of the professional leagues of physicians, pharmacists, dentists, druggists, lay practitioners (*heilpraktiker*), veterinarians and the organizations that aid in medical and social service (nurses, practical nurses, midwives) to declare their adherence to the reorganization plans of the new government. In addition, the *Reichszentrale für Gesundheitsführung*, a subdepartment of the federal ministry of the interior, to which all the federal mergers concerned with health administration belong, will be merged with the new health division that will take over the practical sanitary organization of the government's field work. All the organizations and professions that contribute to the uplift of public health and associated fields of endeavor will be merged to cooperate in the promotion of emergency field work.

The question of the *heilpraktiker*, or lay practitioners, will not be solved so quickly as was expected at first. The deliberations on the law pertaining to *heilpraktiker*, the general plan of which was explained in *THE JOURNAL*, March 10, page 781, will not be completed for some time. Certain regulations, however, have been adopted to eliminate at once certain bad practices. For example the director of the *Heilpraktikerbund Deutschlands* has issued an order prohibiting all *heilpraktiker* from resorting to any form of unethical advertising, whether through notices in newspapers or by the distribution of printed matter. He states that it is not compatible with the dignity of the *heilpraktiker* profession to refer in advertisements to testimonials (even in a roundabout way) or to laud the merits of "cure-alls." Such forms of solicitation must be omitted. All *heilpraktiker* are instructed to report immediately advertisements of this nature that appear (after Feb 5 1934) in order that such practitioners may be proceeded against with all vigor. The only advertising that a *heilpraktiker* may employ is the insertion of a notice in which, after his full name he calls attention to his practice (or, if need be to a change of address) the only details that are permissible

being the mode of treatment, the special fields of practice, and the office hours

How difficult the "incorporation of the heilpraktiker" as planned by the government will be, and what propaganda these lay practitioners are resorting to, is evident in a request of the federal minister for popular education, addressed to the "leader" of the medical profession, Dr. Wagner, asking him to call the attention of the heilpraktiker, the "nature doctors" and the "life reformers" to the fact that attempts to increase their clientele by playing on the government's newer demographic plans will not be permitted. All propaganda must be carried on in closest agreement with the competent provincial or federal propaganda center of the ministry.

Another plan of the league of heilpraktiker, to give 450,000 free treatments for the winter aid society, suffered shipwreck. The offer was made without the knowledge or desire of the director in charge of all matters pertaining to public health and was rejected by the Winterhilfswerk. It has now been decreed that all meetings of heilpraktiker, together with the distribution of circulars and other printed matter, must be approved by the director of the Heilpraktikerbund of Germany. This league alone has still the free right of assemblage.

Bathing and Drowning

Professor Eckert-Mobius, in addressing the *Verem der Aerzte, Halle-on-Saale*, said that disorders of the ear and upper air passages resulting from bathing are seldom caused by a long stay in the water but by neglect to keep the body warm before or after bathing. Such colds are usually induced by drafts, which cause rapid cooling of the wet skin, either before or after the bath, in persons who are predisposed to colds. Occasionally, an infection develops as a result of the entrance of water into the mouth and nose. Swallowing of the water or sneezing may carry germ-laden water (the germs being in the water itself or in the nasal flora) into the sinuses or middle ear. The best protection against such things is a correct swimming technic and avoidance of swallowing water. Mouth breathers should refrain from swimming entirely. In persons who have a perforation of the tympanum, an acute otitis may develop also through the entrance of water by the external meatus. Temporary hardness of hearing occurring after bathing is usually due to the swelling of a pellet of ear wax from the invading water. Finally, traumatic injuries of the ear may be considered. Comparatively frequent are contusion and laceration of the tympanum, resulting from violent compression of the air column in the external meatus in connection with poorly organized jumping, and particularly with the headspring. The contusion may be complicated by an infection of the tympanum or by an acute otitis media. Much more dangerous are irritations of the vestibular apparatus, which may develop through the entrance of cold water through a perforation of the tympanum or a large defect left after a radical operation. Such irritations cause disturbances of the equilibrium, which, in swimming under water, make it next to impossible to find one's way back to the surface. In sudden death resulting from jumping or diving, the possibility of such a "vestibulum death" should be considered. In case a swimmer has an impaired tympanum, it is wise to put in the ear a tight-fitting tampon of greased cotton, before entering the water.

Professor Walcher pointed out that the entrance of infection into the sinuses and middle ear may be facilitated by vomiting and the expiratory efforts that occur in persons saved from drowning. Lacerations of the gastric mucosa may sometimes be due to this increase of pressure. Sudden death in the water may occasionally be due to shock. Consideration must be given also the marked changes of pressure within the chest and to disturbances in the blood flow to the heart due to severe struggles in the water, possibly with upward displace-

ment of the diaphragm, and to filling of the gastro intestinal tract with chyme, gas or air, favored by the pressure of the water, particularly on the abdominal wall. At necropsy, experts always look for lacerations of the tympanum. In deciding whether drowning or sudden death in the water occurred, all the circumstances of the case must be studied and if there were witnesses they must be closely questioned. In many cases, when the body is not discovered until some time after the accident, no certain decision can be reached. In the absence of pronounced evidence of drowning, one should not immediately assume that a heart attack occurred in the water, a rule that plays an important part in expert decisions bearing on insurance. Many cases cannot be clarified from a purely morphologic point of view.

Incidence of Suicide, 1925-1932

According to a report issued by the federal bureau of statistics, 18,625 persons in Germany committed suicide in 1931, which is an increase of 745 over 1930. A conservative estimate places the number of suicides for 1932 at 18,000. The number of suicides recorded for the eight-year period from 1925 to 1932 was 134,933. The incidence of male suicides ranges around 70 per cent, whereas in 1931 the total female suicides (5,491) amounted to 30 per cent. In connection with the increase in the number of suicides for the year 1931, as compared with that of 1930, it should be noted that a large portion of the men were more than 60 years old. The juvenile suicides declined considerably, reaching about the low figures for 1913.

BUCHAREST

(From Our Regular Correspondent)

May 8, 1934

Association Establishes a Syndicate Office

The board of the national medical association resolved to establish an office to deal with all disputed problems of the profession. The office will include a legal section, which will be at the disposal of practicing physicians. The office will form an integral part of the association, but it will work quite independently. The reasons for the foundation of the syndicate office are as follows. The financial crisis has affected the medical profession. The association has found that many private patients try to evade their obligations to pay the doctor's fees. It will be the duty of the syndicate office to settle disputes between physicians and the families of patients. Another activity of the syndicate will be to act as counsel before the courts for physicians against whom legal proceedings have been brought for professional offenses or for matters connected with their professional responsibility. As in most such cases reasonable judgments can be brought only by hearing experts in the various specialties, the syndicate will send a representative to every trial and, if necessary, the representative will force a hearing from the standpoint of the national medical association. It will be the task of the syndicate to study all drafts of new bills concerning the profession.

A Law on the Cumulation of Medical Positions

The principal paragraphs of a new law are as follows. No one shall be allowed to fill more than one position that pays a salary, wage, daily or extra allowance by the state or by a county, parish, monopoly, sick club or similar institution, the budgets of which are subject to the approval of the government, a county, a city or a clerical suzerainty. Scientific staffs adjuncts, assistants and junior dressers who work at scientific institutes and devote their whole time to scientific work, without practicing may occupy a second salaried position. Any official physician may occupy other paid positions, if these are not declared incompatible with the law and the

sum total of his pay does not exceed 16,000 lei monthly (about \$150). Disobedience to the law will be punished with loss of positions and also a fine of three times the amount of the illegally received annual payments.

Medical Advertisements in Newspapers

Since 1931, a medical chamber organization has been functioning in Rumania as a blessing to private practitioners. By strict execution of the law on the cumulation of positions, the chamber has helped more than 400 physicians to acquire employment. The chamber, however, has been indulgent of the offenses of advertising in daily papers and even of placing posters on the streets. Leaflets have been pasted up in Bucharest, with the following text: Medical Consultation Bureau, 250 Sos Stefan cel Mare. Cures genito-urinary diseases with guaranty. Diathermy. Ultraviolet rays. All kinds of injections, surgical operations and dressings. Open from 8 a m to 9 p m. The medical chamber took energetic measures to stop these anomalies. It is drafting a bill to require that all advertisements of a medical character shall before publication come before the special censoring office of the chamber. It is expected that this bill will be passed by the chamber of deputies early next month.

The Sale of Gluside Becomes a Monopoly of the State

The draft of a bill has been passed to the national assembly providing for a monopoly of the purchase and sale of gluside. The reason is that lately the consumption of sugar has diminished immensely because large quantities of gluside are smuggled into the country from Czechoslovakia. If only the monopoly office may import gluside and sell it only to pharmacies, smuggling will come to an end, but it will make gluside very expensive, for a tax will have to be paid to the treasury on each kilogram. The medical periodicals object to this exorbitant tax on a drug, which is indispensable to a great number of patients, who have to use it for years.

RIO DE JANEIRO

Kymography

Cabello Campos and Dante Pazzanese presented to the Society of Medicine and Surgery of São Paulo results of a careful roentgenologic study of organs in movement. Of known clinical entities, the kymogram is particularly interesting in aortic insufficiency. Generally it presents ample waves in the region of the aorta, owing to the great expansion and retraction of the vessel in this disease. In tricuspid insufficiency there is increase of the movements of the right auricle and of the venous movements. In aortic stenosis it shows waves of slight amplitude in the region of the left ventricle and of the aorta. In mitral lesions it has no characteristic aspect. In disturbances of rhythm the kymogram allows the diagnosis of a large number of arrhythmias through the analysis of the auricular and ventricular waves and of the time relations between them. For instance, in total block there are six, seven or eight auricular waves for three or four ventricular waves. In complete arrhythmia all waves are irregular in form, amplitude and aspect. In taking kymograms in arrhythmias it is advisable to diminish the speed of the film in order to obtain a larger number of beats. In cases of tumors of the mediastinum the kymogram contributes much to the clearing up of doubtful diagnosis. The advantages of the method extend to the diagnosis of sclerosis of the vessels, of pericarditis with effusion, of adherences of the pericardium and like conditions.

The authors give an outline of kymography taken from the original work of Stumpf, *Das Roentgenographische Bewe-*

gungsbild und seine Anwendung 1931, and present a series of kymograms, which they think are the first to appear in Brazil, obtained with an apparatus constructed under their direction.

The New Hospital of São Gonçalo

The Hospital of São Gonçalo in the state of Rio with the cooperation of the state government and the municipality has just been finished. The hospital consists of two wards for men and women, a ward for children, a maternity ward and private rooms. There is an x-ray room, pharmacy, laboratory, and the following clinics: medical, surgical, pediatric, gynecologic, ophthalmologic, otorhinolaryngologic, odontologic, venereologic and phthisiologic for outpatients. A school for nurses is being founded by the direction of the hospital.

The Exploitation of Physicians

Owing to the economic crisis, which is made worse by the ever increasing work of the socialization of medicine, there has been some agitation among physicians of the large Brazilian cities to find a means to diminish the exploitation of physicians. Gratuitous medical services exist in all kinds of associations, in so-called orders, having thousands of members, which are in fact rich corporations that pay small fees to physicians. Besides the Brazilian Medical Syndicate, which aims to defend the interests of the profession, a large number of young physicians have decided on an intensive campaign to serve better the medical class. They hold well attended meetings in an effort to vindicate the physicians harmed by those who try every means to exploit the medical profession. This campaign of the young physicians is awakening much sympathy. It aims at uniting the interests of a noble profession against the constant and increasing exploitation of rich societies that remunerate physicians in an insignificant way for their services.

JAPAN

(From Our Regular Correspondent)

April 11, 1934

Japan's Greatest Medical Meeting

The ninth general meeting of the Japan Medical Society was held April 1-5, after an interval of four years, at the great hall of the Tokyo Imperial University, with Dr Tatsukichi Irisawa in the chair, 5,620 members were present and 2,512 papers were read, of which 159 papers were read in the section on microbiology and 158 in the section on pathology. These two sections were the first in number of papers. It was the greatest medical meeting ever held in this country. A number of guests from China proper, Manchuria and India delivered addresses.

In his opening address, Dr Irisawa recalled that this society originated at a gathering in 1890 of a few medical men in Tokyo. There was a second conference in 1893, and then, for the first time, all the medical societies united and the Japan Medical Society came into being. The first general meeting of the society was held in 1902, with sixteen sections. The number of the sections gradually increased and at the seventh meeting there were twenty-four. At the eighth meeting there were twenty-eight, but this year there were thirty-two sections each having its meeting. This indicates a rapid progress in medicine in this country in a short period.

On the first day Dr Y. Fujikawa delivered a special lecture on "A Historical View of Medicine." He treated the subject from the scientific, philosophical and moral points of view. He acknowledged the essential part of science in medicine but pointed out the danger to which too much reliance on mere science is apt to lead, without remembering that man has a soul. He referred to the important influence of philosophy on modern medicine. He concluded that medicine should be an art of the highest order and that medical education should be

based on this principle. The next special lecture was delivered by Dr. Kenji Takagi of the Imperial University, on the progress of orthopedic surgery and the treatment of cripples. Dr. T. Goda, surgeon general, spoke on the military medical service in the recent Manchurian trouble, and he exhibited many appliances and instruments that were used on the field of battle. The thirty-two sections held their meetings on and after the second day. Various prizes were awarded to celebrate strenuous years of study and research. The scholarship founded by the late Dr. Asakawa was awarded to Drs. Hata, Matsumura and Ishihara for their experimental study of disinfectants. The Imperial Gift was conferred on Drs. N. Onodera and S. Kanegae for their research on the gastric movements.

In the section on pathology, Dr. T. Kimura read a paper on morphologic examinations for glycogen in animals. There were heated discussions for and against his point of view from the 600 members present. The pathology of rice disease and beriberi in infants were among other subjects discussed in the 158 papers read before the section. In the section on medicine a paper was read by Dr. F. Sakuragawa on high and low blood pressure. He critically reviewed all the so-called causes of high blood pressure to the greatest satisfaction of all present. Fifty-three papers were read in three days. Vitamin B deficiency disease, beriberi, heart disease and Manchurian fever were important considerations. A subject proposed for the next meeting is diseases of the red and white blood corpuscles.

One of the most successful meetings was that of the section on surgery. Drs. M. Nakata and E. Karasawa's paper on idiopathic gangrene, reporting work of especial significance, was allowed over one hour for reading, while others were granted only ten minutes apiece. An important report on surgery of the chest was given by Dr. Sewo of Chiba Medical College and his colleagues. Surgery of the sympathetic nerves was a popular study in every college, and many papers were read.

In the section on pediatrics, beriberi in infants was discussed by Dr. T. Ota, who said that there are two diseases found only in Japanese medical books—"nurslings' beriberi and nurslings' encephalitis." The latter was demonstrated by Dr. Hirai to be lead poisoning from face powder used by the mother. The cause of the former condition has not been definitely established but the disease is considered to be a nutritional disturbance caused by vitamin B deficiency. Arguments arose on every side that it was caused by poisoning by the milk from mothers who have beriberi, as well as by vitamin B deficiency. Neither side would yield, earnest debates proceeding without end. Yet Hirai's thorough investigations of how this disease affects the infant stomach, intestine, breathing, blood nerves and nutrition, is said to be the most important literature available on this disease.

In the section on hygiene were discussions of research on the contents of rain and snow and their relation to purification of the air, architecture and humidity, on the amount of sunlight in Tokyo, on soy bean powder and its use, and on social insurance in this country.

In the section on tuberculosis there were discussions about the relation of diabetes and tuberculosis. Dr. Kakinuma's paper on treatment was the most striking feature of this section.

In the section on pathology, among many papers, the report of Dr. Mitamura of the Epidemic Research Institute on the cause of smallpox again brought forth a fervent discussion. A paper on jaundice and one on the cause of tsutsugamushi disease attracted much attention. Professor Kimura of the Tohoku Imperial University reported that he had discovered a nerve fiber which, when severed from the cell from which it originates, does not always undergo degeneration. The problem of anatoxin was discussed in a special round table in the section on microbiology, the chief points of interest were

the effects of anatoxin, the interval of vaccination and the proper age and season to vaccinate against diphtheria. The discussions will be printed in pamphlet form in the near future, to be distributed among the members.

The problem of blood types and temperament was a matter of earnest discussion in the race hygiene section, which for the first time held its sectional meeting during this general meeting.

On the last day, April 5, Dr. T. Sasaki read a paper before the general meeting on future methods of research. He insisted that between the special branches there was a gap, which tends to prevent the thorough study of medical science. To be successful there should be established a close relationship. Chemistry and pathologic anatomy, for instance, ought to be studied much sooner in close relation with each other.

The Best Age at Which to Marry

Become a father at 30 or a mother at 24 was the advice given by Mr. Shigeru Ohotomo of the Osaka Educational Research Institute before the society of applied psychology at the Kyoto Imperial University. At those ages, one's chances of having brilliant children are 94 out of 100. Mr. Ohotomo studied 12,104 primary school children in Kobe and graded the pupils into five classes of intelligence. He found that the majority of boys that had the highest grades had 30 year old fathers and 24 year old mothers. The ages of the parents of the girls having the highest grades varied a little from those of the boys. Those girls usually had fathers aged 39 and mothers of 26 or 27 when they were born. Children with low intelligence rating often had parents of advanced ages. Another deduction made by him was that the difference in age between husbands and wives had a great bearing on the intelligence of their children. He said that 45 per cent of the children in the highest group had parents whose ages differed from four to seven years.

Smallpox

The total number of cases of smallpox in 1933 in this country is reported to have been 376 of which 56 were fatal. In the prefectures where the army returned home from Manchuria, comparatively more cases broke out. The source of this epidemic is reported to have been China, Manchuria and Korea. Of seventy-three cases found out in Tokyo, most of them were among Koreans, who are prevented by ignorance and superstition from being vaccinated. Compulsory inoculation among the native born Japanese is easy, but as the Koreans are often without any fixed residence, regular inspection and vaccination are almost impossible.

Marriages

FREDERICK PILCHER JR., Rochester, Minn., to Miss Marjorie McGuire of Petersburg, Va., March 24.

WYATT EARLE ROYE, Richmond, Va., to Miss Anne Estelle Taylor of Bowlers Wharf, March 22.

HERMAN STUART FLETCHER to Miss Helen Louise Overmann both of Richmond Va., April 4.

JAMES WOODFIN KEEVER to Miss Beulah Icard Streetman, both of Hickory, N. C., May 20.

WESLEY G. FORSTER Taylorville, Ill., to Miss Calista Rose Cleary in Chicago, May 19.

KAGEYAS WAT AMANO to DR. FUMIKO YAMAGUCHI, both of Los Angeles, May 14.

JAMES ASA SHIELD to Miss Frances Richardson, both of Richmond Va., April 14.

JACOB JACOBOWITZ to Miss Ruth Lepostat both of New York, April 15.

ALLEN W. LANE to Miss Frances Barrow, both of Blackstone, Va., April 7.

FRED T. HAUSER, Bland, Va., to Miss Juanita Shannon, February 22.

Deaths

Frederick Erasmus Franchere, Sioux City, Iowa, University of Minnesota College of Medicine and Surgery, Minneapolis, 1890, member of the Iowa State Medical Society, past president of the Woodbury County Medical Society member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons formerly professor of nervous diseases and secretary of the faculty and professor of ophthalmology and otolaryngology, Sioux City College of Medicine, at one time coroner of Watonwan County, Minn., and health officer of St James, Minn. on the staffs of the Lutheran and St Vincent's hospitals, aged 67, died, April 28

George Paul La Roque ♂ Richmond, Va University of Pennsylvania School of Medicine, Philadelphia, 1902, professor and head of the department of clinical surgery, Medical College of Virginia, since 1928, and associate professor of surgery, 1910-1927, member of the Southern Surgical Association, fellow of the American College of Surgeons surgeon to the Memorial, Dooley and St Philip hospitals and the Retreat for the Sick, aged 57, died suddenly, May 16, in Cincinnati, of heart disease

Raoul Arthur Amador, Paris, France College of Physicians and Surgeons in the City of New York, Columbia University, 1897, veteran of the Spanish-American War Consul General for Panama in New York, 1905-1907 president of the League of Nations Council and Panama's Minister to France secretary of the Legation of Panama in France officer of the Legion of Honor, aged 59, died, March 23, of pneumonia

Albert John Hoskins, Albuquerque, N M, College of Physicians and Surgeons, Baltimore 1904 commissioned in the U S Army in 1911 and resigned in 1917, commissioned in the U S Public Health Service in 1917 and served in different capacities aged 58 medical officer to the U S Veterans' Administration Hospital, where he died, April 28 of cerebral hemorrhage

George Frank Wilbur, Asbury Park, N J, University of Pennsylvania School of Medicine, Philadelphia, 1882, member of the Medical Society of New Jersey, member of the board of health for six years and for many years school physician, member of the board of medical examiners, 1894-1895, 1899-1900 and president 1897-1898, aged 77, died, April 1

Daniel Joseph Donovan ♂ New York College of Physicians and Surgeons in the City of New York, medical department of Columbia College, 1887 past president of the International Association of Police and Fire Surgeons, chief surgeon of the police department, aged 68, died, May 2, in a local hospital, following an operation for appendicitis

Charles Wendell Townsend, Ipswich, Mass, Harvard University Medical School Boston 1885, member of the Massachusetts Medical Society, formerly on the staffs of the Massachusetts General, Boston Lyng-In and the Children's hospitals, Boston, and the Seashore Home for Sick Children, Winthrop, aged 75, died, April 3, in Boston

Alexander Hayden Lindsay, Amarillo, Texas, Memphis (Tenn) Hospital Medical College, 1898, member of the State Medical Association of Texas past president of the Potter County Medical Society, formerly on the staffs of St Anthony's and Northwest Texas hospitals, aged 72, died, March 25 of chronic myocarditis

James Albert Davis, Covington Ky Pulte Medical College, Cincinnati, 1893 at one time professor of anatomy and lecturer on orthopedics at his alma mater served during the World War for many years on the staff of the Bethesda Hospital, Cincinnati, aged 67, died, March 23, of cerebral hemorrhage

John Henry Flynn ♂ Brooklyn, Tufts College Medical School Boston, 1913, fellow of the American College of Surgeons served during the World War, aged 45 surgeon to St Mary's Hospital where he died March 28 of black water fever, which developed while on a cruise to the West Indies

Grant Sherman Peck ♂ Denver University of Michigan Homeopathic Medical School, Ann Arbor 1890, at one time professor of otology, rhinology and laryngology, and treasurer of the Denver College of Physicians and Surgeons aged 69 died April 21 in Rochester, Minn. of carcinoma of the stomach

Spencer Allen Colliom ♂ Texarkana Texas Kentucky School of Medicine, Louisville, 1892, fellow of the American College of Surgeons, on the staffs of the Texarkana (Texas)

Hospital and St Louis Southwestern Hospital, Texarkana, Ark., aged 67, died suddenly, April 26, of heart disease

Arlington Clare Holland ♂ Colorado Springs Colo., Starling Medical College, Columbus, 1896, past president of the El Paso County Medical Society, formerly registrar of vital statistics in Ohio, on the staff of the Beth-El Hospital, aged 60, died, April 28 of coronary thrombosis

Thomas Scott Hening, Jefferson, Va., Medical College of Virginia, Richmond, 1894, for many years member of the state senate, county board of health, county coroner and judge of the juvenile court, aged 61, died, April 29, of carcinoma of the cardiac end of stomach and esophagus

Carle Lee Felt, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1894 member of the Medical Society of the State of Pennsylvania, for many years on the staff of the Stetson Hospital aged 64, died May 2, of hypertension and cardiac hypertrophy

Jane Nye Gilliford, Pomeroy, Ohio, Kansas Medical College, Medical Department of Washburn College, Topeka, 1899 Pulte Medical College, Cincinnati, 1900, member of the Ohio State Medical Association, formerly county health officer, aged 66 died, April 23

Albert Leroy Beahan, Canandaigua, N Y, Bellevue Hospital Medical College New York, 1879, served with the American Red Cross in France during the World War formerly member and chairman of the county board of supervisors, aged 79, died, March 23

Joseph L De Cock, Green Bay Wis Milwaukee Medical College, 1907 member of the State Medical Association of Wisconsin county physician, on the staffs of the Bellin Memorial, St Mary's and St Vincent's hospitals, aged 53, died April 14

Clarence Irvin Britt ♂ Columbus, Ohio, Ohio State University College of Medicine Columbus, 1920 on the staffs of the Grant, St Francis, White Cross and the Columbus Radium hospitals, aged 41, died, May 4, in Trudeau, N Y, of tuberculosis

Isaac George Babcock ♂ Cumberland Wis, Bellevue Hospital Medical College, New York 1888, past president and secretary of the Barron-Washburn-Sawyer-Burnett Counties Medical Society, aged 70, died, May 9, of heart disease

George Bennett Fielding, Brooklyn, Long Island College Hospital, Brooklyn, 1899, member of the Medical Society of the State of New York, aged 59, died, April 3 in the Doctors Hospital, New York, of carcinoma of the larynx

Charles Gordon Bohannon ♂ South Norwalk, Conn, University of the City of New York Medical Department 1878, formerly mayor of South Norwalk, on the staff of the Norwalk (Conn) Hospital, aged 81, died, April 19

Jesse C Bennett, Jefferson, Ga, Atlanta Medical College, 1890, member of the Medical Association of Georgia, secretary of the Jackson-Barrow Counties Medical Society, aged 65, died suddenly, April 19, of diabetes mellitus

Thomas J Conley ♂ Chicago, Rush Medical College Chicago, 1885, on the staff of the Westside Hospital and formerly on the staff of the Cook County Hospital, aged 75, died May 13, of coronary thrombosis

William Marshall Friend, Park Ridge, Ill Washington University School of Medicine, St Louis, 1895 member of the Illinois State Medical Society, aged 63, died, May 6, of uremia and chronic nephritis

Joseph Stevenson J Manning ♂ New York, College of Physicians and Surgeons in the City of New York, Medical department of Columbia College, 1890, aged 64 died, April 25, of coronary thrombosis

Edwin Daniel Frear, Danbury, Iowa, State University of Iowa College of Medicine, Iowa City 1882 formerly professor of hygiene and dermatology, Sioux City College of Medicine, aged 79, died, March 19

Vincent Aloysius Callery ♂ Pottsville, Pa University of Pennsylvania School of Medicine Philadelphia 1925 on the staff of the Lemos B Warne Hospital, aged 39, died, April 28 of pneumonia

Charles Wilhelm Eisenhower ♂ York, Pa Jefferson Medical College of Philadelphia, 1903 past president of the York County Medical Society, aged 61, was found dead, May 21, of a bullet wound

Herbert Wyche Cruik-Shank, Cleveland, Harvard University Medical School, Boston 1895, superintendent of the General Hospital Clinic, aged 65, died, March 31, of hypertension and uremia

Robert Y. Ferguson, Pontiac, Mich., Detroit College of Medicine, 1896, member of the board of education, on the staff of the Pontiac General Hospital, aged 63, died, March 20, of heart disease

Robert J. Hillis Ⓢ Altoona, Pa., College of Physicians and Surgeons, Baltimore, 1886, on the staff of the Mercy Hospital, aged 71, died, February 25, in the Bradenton (Fla.) General Hospital

Joel Carlton Brown Ⓢ Lewistown, Mo., Rush Medical College, Chicago, 1886, past president of the Lewis County Medical Society, aged 72, died recently, in Columbia, of angina pectoris

Shirley H. Lapp, Mount Morris, N. Y., University of Buffalo School of Medicine, 1921, member of the Medical Society of the State of New York, aged 36, died, April 8, of pneumonia

Robert Thomas Bailey, Central City, Ky., Louisville National Medical College, Medical Department State University, 1910, aged 54, died, April 17, of phenol poisoning, self-administered

Charles Hercules Dale, Springport, Mich., University of Michigan Homeopathic Medical School, Ann Arbor, 1877, aged 82, died, April 24, of hemiplegia, diabetes mellitus and chronic myocarditis

Samuel Saffield Rodgers, Pittsburgh, University of Pittsburgh School of Medicine, 1931, aged 28, resident physician to the Children's Hospital, where he died, March 1, of bronchopneumonia

Albert R. Halsted, Marion, N. Y., University of Michigan Homeopathic Medical School, Ann Arbor, 1881, aged 75, died, April 21, of thrombosis, arteriosclerosis and bronchopneumonia

John E. Golden, Walnut Grove, Miss., University of Louisville (Ky.) School of Medicine, 1874, formerly postmaster of Walnut Grove, aged 84, died, April 4, in a hospital at Jackson

Charles Linn Hathaway, Winslow, Ariz., Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1902, aged 61, died, March 25, of chronic myocarditis and diabetes mellitus

Walter Scott Johnston Ⓢ Pueblo, Colo., Medical College of Ohio, Cincinnati, 1904, on the staffs of the Parkview Hospital and St. Mary Hospital, aged 62, died, May 15, of heart disease

Thomas Hammond Crawford, Coldwater, Kan., University of the City of New York Medical Department, 1881, aged 75, died, March 26, in Steubenville, Ohio, of cerebral hemorrhage

Harry Alfred Zimmerman, Youngstown, Ohio, Miami Medical College, Cincinnati, 1888, member of the Ohio State Medical Association, aged 74, died, April 26, of heart disease

Thomas J. Wolfe, Bowie, Md., Baltimore Medical College, 1890, served during the World War, aged 71, died, in April, at the University of Maryland Hospital, Baltimore

Ludwig A. Kierulff, Chicago, Northwestern University Medical School, Chicago, 1893, member of the Illinois State Medical Society, aged 70, died, May 9, of heart disease

Joseph Sanders, Beaver Dam, Wis., Medical College of Indiana, Indianapolis, 1884, aged 74, died, May 3, in St. Saviors General Hospital, Portage, of uremia

Jesse Franklin Davidson Ⓢ Crawfordsville, Ind., Medical College of Indiana, Indianapolis, 1880, aged 80, died, March 30, of chronic myocarditis and arteriosclerosis

Albert Milton Buzard, Tyrone, Pa., Western Pennsylvania Medical College, Pittsburgh, 1891, aged 78, died, April 16, in the Philipsburg (Pa.) State Hospital

Charles Wellington Fitch, Southington, Conn., Yale University School of Medicine, New Haven, 1874, aged 82, died, March 26, of cardiovascular renal disease

William R. C. Booher, Bristol, Tenn., University of Tennessee Medical Department, Nashville, 1889, served during the World War, aged 67, died, April 4

F. L. Tracy, Anderson, Ind. (licensed in Indiana, year unknown), aged 78, died, January 30, in St. John's Hospital of myocarditis and hypostatic pneumonia

J. B. Whitehead, Voss, Texas (licensed in Texas under the Act of 1907), aged 83, died, February 1, in a hospital at Wichita Falls of cerebral hemorrhage

Nellie Frances de Hay Nunan, Tehri, Tehri-Garhwal, India, Woman's Medical College of Pennsylvania, Philadelphia, 1913, aged 53, died, March 12

Mariam E. Kimball Frisbie, Binghamton, N. Y., Woman's Medical College of Pennsylvania, Philadelphia, 1892, aged 65, died, March 14, of diabetes mellitus

Gilbert La Fayette Clark, Centerville, Pa., Miami Medical College, Cincinnati, 1875, aged 85, died, April 19, in Parkersburg, W. Va., of arteriosclerosis

John James Wade, Coe Hill, Ont., Canada, Queen's University Faculty of Medicine, Kingston, 1906, aged 52, was found dead in his office, March 24

Eustis Randolph Marshburn, Marianna, Fla., Atlanta Medical College, 1914, medical officer of the Western Florida district, aged 47, died, March 25

Robert Alonzo Burke, Dyersburg, Tenn., Vanderbilt University School of Medicine, Nashville, 1894, aged 67, died suddenly, May 6, of heart disease

Arthur L. Nichols, Knowles, Okla., College of Physicians and Surgeons, Keokuk, Iowa, 1895, aged 66, died, February 7, of rheumatism and heart disease

Charles Vinton Artz, Los Angeles, State University of Iowa College of Medicine, Iowa City, 1882, aged 76, died, February 14, of prostatic disease

John N. Taylor, Crawfordsville, Ind., Indiana Medical College, Indianapolis, 1876, aged 84, died, April 26, of gastroenteritis and arteriosclerosis

Vernon Grossenor Danford, Athens, Ohio, Illinois Medical College, Chicago, 1900, served during the World War, aged 57, died, March 15

Beverly Caldwell, China Spring, Texas, University of Louisville (Ky.) School of Medicine, 1881, aged 80, died, April 21, of myocarditis

William R. Bolbaugh, Osceola, Iowa, Drake University Medical Department, Des Moines, 1892, aged 76, died, April 18, of diabetes mellitus

Harry Arthur Boyde, Indianapolis, University of Louisville (Ky.) School of Medicine, 1913, aged 46, died, April 16, of coronary thrombosis

William Harris Daniel, McEwen, Tenn., Vanderbilt University School of Medicine, Nashville, 1891, aged 65, died, April 15, of nephritis

David A. Nunn, Halls, Tenn., University of Louisville (Ky.) School of Medicine, 1871, aged 83, died, April 1, of hypostatic pneumonia

CYSTEX

A "Patent Medicine" of the Kidney and Bladder Cure Type

"Cystex" is a nostrum sold for the self-treatment of self-diagnosed disease conditions of the bladder and kidneys. It is a "shot gun" mixture whose composition, like many "patent medicines," has varied with time. Its present alleged formula is seemingly based on the alternate acid and alkaline treatment of infections of the urinary tract, although it contains neither enough acid nor alkali to be effective.

HELP KIDNEYS

don't take drastic drugs

Good Kidney Action P. See You
Blood—Often Removes the Real Cause
I Get Up Night Nerve
rains and Rheumatism
Quiet Jumpy Nerves and 10 Year
You Feel 10 Years Younger

FAVORITE kidney and bladder
cure of men and women
and young people
suffer from urinary troubles
and that is often the real cause
of feeling tired, nervous, getting
up at night, rheumatic pains
and other troubles
If poor kidney and bladder function
causes you to suffer from any
of the following symptoms:
Getting Up at Night, Backache, Leg
Pains, Nervousness, Lumbago, Stiff
ness, Headaches, or Rheumatic Pains
Dark Circles Under Eyes, Headaches,
Frequent Colds, Burning
Smarting or Itching Acidity, you can't
afford to waste a minute. You
should start testing the Doctor's
Prescription called Cystex (pronounced
Sis-tex) at once.

Dr. H. T. Allen
New York Doctor
Famous Cystex

Cystex
It's
Guaranteed

Greatly reduced photographic facsimile of a Cystex advertisement—1934 vintage

Like most of the "patent medicines" today, Cystex is advertised under claims that are implied rather than stated. An advertisement (see illustration) occupying two-thirds of a page in a motion picture magazine, details the alleged virtues of Cystex in these words:

If poor Kidney and Bladder functions cause you to suffer from any symptoms such as loss of Vitality, Getting Up at Night, Backache, Leg Pains, Nervousness, Lumbago, Stiffness, Neuralgia or Rheumatic Pains, Dizziness, Dark Circles Under Eyes, Headaches, Frequent Colds, Burning Smarting or Itching Acidity, you can't afford to waste a minute. You should start testing the Doctor's Prescription called Cystex (pronounced Sis-tex) at once.

In the same advertisement the public is told that Cystex is not only a "gentle and to the Kidneys," but, in addition it "soothes and tones raw, sore, irritated bladder and urinary membranes." While the general trend of the advertising is to recommend it for conditions already described, the circular that goes with the trade package also suggests that women use it, as it is "of great value during the menstrual period." In the same circular the public is told to take Cystex for "head colds."

The theme that the stuff is a cure for kidney diseases" is played up thus:

Clean Out Your Kidneys. Win Back Your Pep. Good Kidney Action Purifies Your Blood—Often Removes the Real Cause of Getting Up at Night. Neuralgia and Rheumatic Pains—Quiets Jumpy Nerves and Makes You Feel 10 Years Younger.

The exploiters of Cystex seem to have made a practice of publishing as part of the trade package (which comes under the purview of the National Food and Drugs Act) a list of the ingredients of Cystex (no quantities given) and have comparatively recently, in a drug journal, published what is alleged to be the quantitative formula of this "patent medicine." Like so many "patent medicines," the composition of Cystex has changed, although the name has remained the same. As has been emphasized before, when one buys a "patent medicine," one buys a name rather than a thing.

Cystex comes in tablet form, the package containing two kinds of tablets, gray and brown. Prior to 1929 the gray tablets were claimed to have the following ingredients:

Hexamethylenamine	Calcium phosphate
Powdered Extract of colchicum	Thyroid substance

Later the thyroid substance was dropped out of the formula, but for a while the other three ingredients were retained. Today the gray tablets have a very different composition, as will be shown shortly.

The brown tablets, prior to 1929, were said to contain the following substances:

Extract of hydrangea	Potassium bicarbonate
Extract of buchu	Boric acid
Extract of corn silk	Atropine sulphate
Extract of tritium	

The composition of these brown tablets has not undergone the drastic changes that the manufacturers have made in the gray tablets, although the extract of hydrangea has been dropped, sodium borate has taken the place of boric acid, and caffeine has been added.

In a publication, *Drug Topics* for October, 1933, there was a full-page advertisement headed "Cystex Has No Secrets." There was given in this advertisement what purported to be the "actual working formula" of Cystex. This read as follows:

GRAY TABLETS	
Hexamethylenamine	2 1/4 grains
Extract Nux Vomica	1/4 grain
Acid Benzoic	1/2 grain
Atropine Sulphate	1/800 grain
BROWN TABLETS	
Extract Buchu 14	1/2 grain
Extract Corn Silk 15	1/4 grain
Extract Tritium 13	1/2 grain
Potassium Bicarbonate	1 grain
Sodium Borate	1 1/2 grains
Atropine Sulphate	1/800 grain
Caffeine	1/8 grain

This, then, presumably represents the quantitative formula of Cystex as sold today. The directions for taking Cystex are to take six gray tablets a day (two after each meal) for five days, then six brown tablets a day for three days, and keep this dosage up, alternating with five days of six gray tablets each day and three days of six brown tablets a day.

In addition to the extensive advertising campaign in magazines and newspapers, it appears that Cystex is also being advertised by radio. In the latter part of March a letter came in from Dr. F. G. Benn, Chairman of the Interprofessional Relationship Committee of the Hennepin County (Minneapolis) Medical Society. He sent with his communication a letter that had been sent to a Minneapolis druggist and was evidently one of many sent rather generally to druggists in that locality.

The letter was on the stationery of broadcasting station KSTP, owned and operated by the National Battery Broadcasting Company of St. Paul, and was signed Ford Billings, General Sales Manager. Mr. Billings' letter stated that more than five hundred local druggists had been given free advertising by the makers of Cystex in the series of Cystex broadcasts and that Mr. Billings was writing to the druggist to whom his letter was addressed, extending to that druggist free publicity on a certain program. The letter went on to state that on a certain date mentioned in the letter, if the druggist was willing, the announcer would give the druggist's name and business address at the start of the program as sponsoring the following statement:

I wonder how many of you listeners realize that your kidneys work while you are asleep or awake? The kidneys must remove poisonous wastes and uric acid from the blood or your system becomes slowly but

surely poisoned That is why functional kidney disorders are often the real cause of your sleep being ruined nervousness leg pains, stiffness burning acidity, neuralgia or rheumatic pains lumbago loss of vitality and many other troubles But you must be careful not to take drastic, irritating drugs which may endanger the kidneys I think the best prescription for functional kidney and bladder disorders is Cystex It works fast circulating through the system in 15 minutes I know the formula and that Cystex is safe and pure For these reasons and because it is guaranteed to fix you up or money back I always recommend Cystex to my customers

In order, apparently, to allay any qualms that druggists might have regarding the matter, Mr Ford Billings, following the quotation of the statement that was to be sponsored, went on to state

This statement has been approved by the American Medical Association and by your own trade association A prominent physician makes a similar statement at the end of the program

Needless to say, the claim that any such statement as the one quoted had been approved by the American Medical Association is a crude and gratuitous falsehood It appears, also, from Dr Benn's letter that the claim that the statement had been endorsed by the Retail Druggists Association was equally without foundation The owners of KSTP were written to telling them that the statement "approved by the American Medical Association" was 100 per cent false and they were asked for an explanation This letter was written March 29 1934 and was acknowledged by the secretary of Mr Stanley E Hubbard Vice-President and General Manager of the company It was stated that Mr Hubbard was out of the city "but the matter will receive his attention immediately upon his return which will be within a few days" This was two months ago No letter or explanation has been received

As part of the present advertising of Cystex, there appear the inevitable testimonials by physicians Among the testimonials that grace the Cystex advertisements is one credited to a Dr N T Abdou of New York City According to the files of the American Medical Association, this is Nagib Tannous Abdou of New York City, who was born in Syria in 1875 and holds a diploma from the School of Medicine and Surgery of Montreal Faculty of Medicine of the University of Laval, issued in 1900 He was licensed in New York in 1915 and in Colorado in 1917 It is hardly necessary to state that he is not a member of his local medical society

Another Cystex testimonial is stated to be from "Dr Charles Z Rendelle" of San Francisco So far as the records show, there is no man of this name who is a licensed physician There is, however, a Charles Q Rendell of San Francisco whose name appears in various unsavory connections in the files of the Bureau of Investigation This man holds a diploma from the Albany (N Y) Medical College for 1914 and is licensed in New York and California He is not a member of his local medical society or of the American Medical Association Information on file indicates that Dr Rendell three or four years ago was connected in some way with a cancer quackery operated by one W F Hoque of San Jose, who was found guilty of violating the medical practice act of the State of California and fined \$500 Dr Rendell's name also appears in connection with a testimonial for "Kruschen Salts" According to official reports received from California, Rendell was in 1927 connected with a quackish concern known as the Gilbert Thayer Health Foundation which seemed to be made up mainly of chiropractors and osteopaths

A third testimonial for Cystex bears the name of Dr W R George, who is described as a graduate of Indiana University and former health commissioner of Indianapolis Dr Walter Reid George holds a diploma from the Medical College of Indiana, 1895 and was licensed in Indiana in 1898 He, of course, is not a member of his local medical society or of the American Medical Association In 1931 Dr George's name appeared in connection with a large and blatant advertisement for "Sargon" So much for the professional standing of the three physicians who testified to the virtues of Cystex

The objection to Cystex is simple and fundamental There is no legitimate place for the self-treatment of pathologic conditions of the kidneys or bladder It is sheer madness for persons who have the symptom complex described in the Cystex advertisements to attempt to treat themselves and waste what well may be vitally valuable time before seeking competent treatment based on a rational diagnosis

Correspondence

THE PHYSICIAN AS MAN OF LETTERS, SCIENCE AND ACTION

To the Editor—In THE JOURNAL, May 12, page 1637, appeared a book notice dealing with the recent work on this subject by Dr Thomas Kirkpatrick Monro of Glasgow, containing some criticism because mention of certain names, chiefly contemporary, is omitted May I point out that not all this criticism is warranted? In the first place, Monro clearly states in the preface that "no living persons are included in these biographies" and thus quickly accounts for the omission of such names as those of A J Cronin, W Somerset Maugham and Francis Brett Young among the writers of fiction, and those of Geddes and Ramon y Cajal among ambassadors and statesmen, since all these persons were alive when the book was written "One seeks in vain under dramatists for the name of Arthur Schnitzler" further complains your reviewer, but had he consulted the biographic index he would have found the eminent Viennese author of "Flight into Darkness," who died in 1931, adequately mentioned in another section

Why no mention of Virchow occurs I do not know, unless it be that his political life was so eclipsed by his preeminence as a man of science, for it seems to have been Monro's intent to emphasize more particularly the examples of physicians who became distinguished in other fields rather than to mention those who had merely become deeply interested Be that as it may, it would seem that Virchow's career as a public official should entitle him to a place in the book, the incompleteness of which is further attested by the fact that there is no mention of Theodor Billroth close friend of Brahms and himself a keen musician and author of a classic on the psychophysiology of music, published posthumously, or of Alexander Borodin, eminent Russian composer whose work was so highly praised by Liszt and who first practiced medicine and then limited his scientific efforts to teaching and research in chemistry, becoming the discoverer of aldol

I fully agree with your reviewer that Monro's book is "an interesting beginning of what might be developed into an important work" The subject deserves more systematic attention than it has received in the past

GILBERT COTTAM, M.D., Minneapolis

LEUKOCYTE COUNTS AND BARBITURATES

To the Editor—I feel that some comment should be made relative to the article of Hardwick and Randall that appeared in THE JOURNAL, May 12 page 1558 These authors studied the leukocyte counts of fifty-nine women who had been given pentobarbital sodium as an obstetric analgesic and concluded that the drug had no effect on the leukocyte count I am in complete agreement with their conclusions since I have also made the same observations relative to all types of the so called barbiturates

The authors state, however, that "there has been some discussion in the literature recently concerning the possible relation between the administration of barbiturates and the production of granulocytopenia" Since I have just completed a review of the literature on this subject I must state that the discussion has centered around the relationship to granulocytopenia of drugs containing the benzene ring and that the barbiturates have not been involved in this conception of the etiology of the disease Pentobarbital sodium is a straight chain carbon compound, does not contain the benzene ring, and has never been suspected of being an etiologic factor, so

far as I know, except possibly in the report of C H Watkins (*Proc Staff Meet, Mayo Clin* 8 713 [Nov 22] 1933) In my original publication on this subject in 1932 (*Am J Clin Path* 2 11 [Jan] 1932) I brought out the observation that eight of nine patients with granulocytopenia had taken drugs containing the benzene ring prior to the clinical onset, and in other publications (*U S Nav M Bull* 30 16 [Jan] 1932, *Am J Clin Path* 1 385 [Sept] 1931) I brought out the same association and I wish to emphasize that in no instances have the barbiturates alone ever been suspected of an etiologic role in this disease

Hardwick and Randall state further, "Madison and Squier reported thirteen cases in which they think granulocytopenia was probably due to the use of benzene chain derivatives" It seems that they have misinterpreted the report of Madison and Squier, since these authors stressed the fact that their thirteen cases had been preceded by administration of a drug which contained the benzene ring and not a carbon chain

Since my first report on this subject there have now accumulated over fifty cases of granulocytopenia in the American literature in which the clinical onsets were preceded by the administration of benzene ring drugs and in no instance, with the exception of the report by Watkins, has the barbiturate group been incriminated There are many preparations, of course, in which the barbiturates and the benzene ring drugs, such as allonal and amylal compound, are combined

Finally I would like to emphasize that my chief purpose in this communication is to call attention to the possible confusion that may exist as to the differences between these two classes of drugs There has been much evidence accumulated to show that many cases of granulocytopenia are probably caused by the indiscriminate administration of benzene ring drugs, and more specifically by those containing the ring with an attached amine group (Kracke and Parker *J Lab & Clin Med*, May 1934) It seems especially indicated at this time that careful distinction should be made between the group of drugs containing the benzene ring and that group under the heading of "barbiturates" which do not contain the benzene ring

University School of Medicine

OVULATION AND MENSTRUATION

To the Editor—I should like to be given the opportunity of replying to Dr Novak's letter in *THE JOURNAL* dated April 21

I agree with Hartman that the disintegration changes in the endometrium during the anovular cyclic hemorrhage of the macaque and during menstruation in the human female are almost identical Probably in metropathia haemorrhagica the same process is also at work So far as the macaque is concerned the disintegration changes seem to be the same whether the cycle is ovular or anovular and one is justified in assuming that the final cause of the bleeding is of a similar nature in these two cases and during menstruation in the human female Robert Meyer and Schroder have suggested that the word "menstruation" should be restricted to the ovular cyclic bleeding and that the term pseudomenstruation should be used for anovular cyclic bleeding The distinction may appear trivial especially as the factor controlling bleeding from the endometrium is probably the same in the two groups but to some of us it is fundamental, if for no other reason than that it distinguishes between cycles which are ovular and those which are anovular I myself feel that the time honored definition of menstruation was intended for women and not for the macaque, and I believe that this definition should be the

basis from which the cyclic bleeding of the macaque should be described

During the investigation which led to the publication of my paper in the *British Medical Journal* (1 7 [Jan 6] 1934) I found no evidence of anovular cyclic bleeding in women with accurately dated menstrual cycles About this time Dr Novak's paper appeared in the *British Medical Journal* in which he dismissed the distinction between "menstruation" and "pseudomenstruation" as "a mere play on words," and it was to this remark that I took particular exception, for, as I have said, the distinction seems to me to be fundamental It is true that I believe that the case for cyclic anovular bleeding in healthy women has been overstated in the American literature, and this opinion is based on studies of material during the last ten years Further, for some time I have become extremely critical of interpretations of work which has been done on the human menstrual cycle for I have become convinced that the controlling factors will prove to be far more complex than is now believed For example, little is known as yet of the atypical corpora lutea which are sometimes seen, in other cases corpora lutea may be found in women suffering from amenorrhea, and many such difficulties can be called to mind

I am most anxious to correct any impression that I have scoffed at any new idea emanating from America and my best answer is to ask those who are interested to refer to my paper in the *British Medical Journal* My friends in America know very well how I regard the work of Corner, Hartman, Allen, Evans and Hisaw among other Americans as the most important contributions to sexual physiology of the present century just as they know my profound admiration of Dr Novak's publications Indeed, I cannot recall a previous occasion when I have differed with him I should be very distressed if Dr Novak's interpretation of my article were accepted in America, for it is quite contrary to what I really believe

WILFRED SHAW, M D, London England

DEATHS OF BABIES OF ONE SEX AT BIRTH WITH OTHER SEX SURVIVING

To the Editor—A white woman aged 37 a farmer's wife had six children The family and past histories are negative Physical examination shows nothing of clinical value The systolic blood pressure is 134 diastolic 82 Examination of the urine gives negative results The Wassermann reaction is negative in both wife and husband She is 5 feet 9 inches (175 cm) tall and 145 pounds (66 Kg) in weight Of the six children two were boys who are living and healthy but all the girls died The first girl was born March 21 1920 lived two months and died apparently of encephalitis (the death certificate stated intracranial pressure) The second girl was born Oct 13 1922 and lived eleven days dying of meningitis The third girl was born Oct 4 1926 and lived eight days dying of intracranial pressure The mother never saw this child The fourth girl was born in October 1931 and lived only two hours All these girl babies were unable to nurse or cry as normal children and were dull in appearance They were born at full term and without instruments The skin of the last born was apparently macerated What seems to be the cause? Why are the males not affected as the females? Is it possible that she has sex hormone deficiency? What can be done to determine the sex before the birth? I have not attended to any of the births but the patient is pregnant now and under my care I need your help

M D Massachusetts

ANSWER—There is hardly anything in the literature that would explain the difficulties encountered in this case There are numerous instances on record wherein women have had abortions and dead children by one husband and healthy offspring from another, and syphilitic parents can have healthy children interspersed among the diseased ones A famous French surgeon was the eleventh child of his parents All the odd numbered children had died and when the eleventh was due the mother made no preparations for it thinking that it also would die but it lived and grew up

Recently, at the Chicago Living-in Hospital, a woman had a light bleeding toward the end of her fifth pregnancy. She had two full term labors with boys. Both died during labor. She had two live girls born and the question came up about the sex of this child. If the child was a boy, would it die in labor? If it was known to be a boy, should labor be induced before term or a cesarean section? The patient settled the questions herself by going home, and later she had a spontaneous delivery of a third living girl.

The methods of determining the sex of the child before birth are not positive, even amniography with skiodan not always being indicative.

SYPHILIS

To the Editor—What is the present status as regards a Wassermann four plus spinal fluid reaction and a negative blood Wassermann reaction in the same patient? To my way of thinking I believe the individual has cerebrospinal syphilis but a medical colleague insists that it is of no value because he obtained a negative blood Wassermann reaction after giving the same patient a provocative treatment or test. The testing in all cases was performed by the local department of health. The patient in question complains of blurred vision especially after looking at an object for any length of time, pressing frontal and occipital headache and disturbed sleep. There are no disturbances in gait or sphincters. My examination revealed a dull listless expression, pupils equal but reacting to light sluggishly, hyperactive knee jerks, slight drooping of the right side of the face and two scars on the corona of the penis that suggest a previous possibly syphilitic origin. Although I did not obtain a clear cut history as to whether or not he was treated for syphilis he possibly had some treatment in 1918. The patient otherwise appears robust and has gained in weight in the past two years. He is 39 years of age. Would a colloidal gold test help clear this question? Kindly omit my name.

M D New York

ANSWER—It is difficult to answer the question with the amount of data furnished. In a case of this sort it probably would be well to take another Wassermann reaction and do another lumbar puncture, having the test made in an accredited laboratory where one can have full confidence in the results of the tests. It is most essential that not only a Wassermann reaction but also a precipitation test be done on the blood, and with the spinal fluid there should be, in addition to the Wassermann reaction in amounts of the spinal fluid from 0.1 cc up to 1 cc, also a cell count, a globulin test and a gold chloride test. With this information one would be in a better position to decide just what the patient's condition is and what should be done for him. It would be well to do a careful physical examination, including a complete neurophysical survey. Undoubtedly the patient has cerebrospinal syphilis. Simply because of a negative blood Wassermann reaction one must not reach the conclusion that the patient does not have syphilis. One often sees patients with that type of reaction on the blood and a positive reaction on the spinal fluid.

DYES FOR CHOLECYSTOGRAPHY

To the Editor—Please discuss for me the absorption, distribution and elimination of dyes taken orally and intravenously for cholecystography. Does the physiology differ with the different dyes used for this work? Any references to the recent literature on this subject will be sincerely appreciated.

JOSEPH H. BARACH, M.D. Pittsburgh

ANSWER—Early in the experimental work on the development of cholecystography it was noted that after intravenous injection of sodium tetraiodophenolphthalein in dogs an x-ray shadow appeared in the large intestine as well as in the gallbladder. It was found that this shadow in the colon was due to the excretion of the dye by the large intestine. Abel and Rowntree had previously observed that phthaleins are excreted by the colon. However, by far the greater portion of sodium tetraiodophenolphthalein was found to be excreted by the liver, apparently without changing its original form. The kidneys are found to excrete a small percentage of dye. After excretion of the halogenated phenolphthaleins by the liver they are carried to the gallbladder by the bile, where they are concentrated. Chemical analyses show that the average concentration of the halogen per unit volume of bile in the gallbladder that produces an x-ray shadow of maximum density is several times that of the bile that does not enter the gallbladder. Analyses also reveal that there is a fairly constant rate of excretion of the halogens in the bile and that the output of the halogens is independent of the rate of excretion of the bile. Sodium phenoltetraiodophthalein, which stains the blood serum bluish red when a sample is alkalinized, disappears from the blood stream in approximately three to four hours after injection.

Recently Delario has studied more extensively the absorption and excretion of sodium tetraiodophenolphthalein. He finds that the dye is absorbed by both the small and large intestines after

oral or rectal administration. The large intestine was found to excrete about 25 per cent of the dye, the liver excreted from 60 to 70 per cent of the dye without changing it or conjugating it, and the urine excreted from 5 to 10 per cent of the dye, some of it in an inorganic state. Delario states that fat causes a greater amount of the dye to be rendered insoluble in the small intestine but causes a greater secretion of the dye and probably a greater gallbladder absorption. Mairano and Biancalana found that from 50 to 70 per cent of sodium tetraiodophenolphthalein is withdrawn from the blood circulation within an hour after intravenous injection. They found as had previously been observed, that iodine appears in the bile as early as ten minutes after intravenous injection of the dye. From their study the investigators concluded that the oral dose of sodium tetraiodophenolphthalein must be twice the intravenous dose.

Apparently the physiology of the different halogenated phenolphthaleins used for cholecystography differs little if at all.

CANCER AND MENTAL SHOCK

To the Editor—A man aged 45 was well until about eighteen months ago. At that time he had the misfortune of killing a child aged 9 while driving. The shock and worry of the trial that followed greatly depressed him; however, he was set free of the charge. Six months after the accident he began to complain of sour regurgitation, dyspepsia and lack of appetite and in two months he became jaundiced. A diagnosis of carcinoma of the stomach with metastasis in the liver was made and verified by roentgen examination and at exploratory operation. He died four months after the operation. My mother, aged 62, who was apparently in good health until August 1932, was a nervous woman always fearing accidents. In August 1932 she fell while crossing the street car tracks, receiving a bruised cheek bone but the fall caused her great mental shock. Apparently a street car was approaching and she thought she would be killed. She overcame her local injury. In October she began to lose weight, become anemic and lost her appetite and her abdomen began to enlarge. Several diagnoses were offered by leading specialists in Toronto. Finally an exploratory operation showed an extensive carcinoma of the ovaries. Hysterectomy was done. She died of general carcinomatosis in June 1933. What I wish to know is this: In each case what relation had the mental shock to the development of cancer? Is there a possible relationship? Has any one had similar cases of mental shock followed by carcinoma? Were the mental shocks in these two cases followed by cancer a mere coincidence? I would appreciate any sources of available literature on these points.

LIONEL MARKS, M.D. Toronto

ANSWER—A fairly complete survey of the literature on the subject of the relationship between mental shock and cancer does not reveal any information of importance. The statement has been made that the inmates of mental hospitals have a proportionally lower mortality from cancer than that which occurs in the general population. This question has been carefully examined and reported on in monograph 36, on Diet and Cancer, by Copeman and Greenwood, published in 1926 in London by the Ministry of Health. In the report, on page 29, the following conclusion is reached: "In other words there is no important difference between the rate of cancer mortality upon inmates of mental hospitals than that upon the general population." Major Greenwood, one of the authors of this paper, is a statistician and the statistical portion of the article was prepared by him.

The following are recent references on some phases of this subject:

- Laursen L. Cancer Mortality and Mental Diseases. *Ugeskr. f. Læger* 94: 238 (March 3) 1932.
Lumière and Vigne. Role of Emotions in Pathogenesis of Cancer. *Bull. Acad. de méd.* 106: 272 (Nov. 3) 1931.
Stajano C. Relation of Psychopathology of Nervous System in Cancer. *Paris méd.* 3: 125 (Aug. 8) 1931.
Forgue. Role of Mental State in Problem of Cancer. *Gaz. d. hop.* 104: 827 (May 30) 1931.
Marullar M. Essai sur l'etiologie des tumeurs. *Ann. de l'Inst. Pasteur* 45: 443 (Oct.) 1930.
Rainhill A. P. Incidence of Cancer over Period of Twenty Five Years at County Mental Hosp. *J. Ment. Sc.* 76: 234 (April) 1930.
Incidence of Cancer in Mental Patients and in General Population of England and Wales Compared. Report of Infectious Disease Subcommittee of the Research and Clinical Committee (Royal Medical Psychological Association). *J. Ment. Sc.* 76: 223 (April) 1930.

The cases cited were probably coincidences. For example in that of a man, aged 45, the cancer of the stomach must have been present at the time of the accident for when the diagnosis was made six months after the accident there were obviously

metastases in the liver. The mean duration of cancer of the stomach has been computed (report 33, Ministry of Health Reports on Public Health and Medical Subjects, on the Natural Duration of Cancer) by Major Greenwood at approximately seventeen months. This period, of course, is computed as from the first symptoms noted and is subject to considerable variations. For instance, in patients between 35 and 44 years of age the mean duration is twenty months, between 45 and 54 years of age the mean duration is about fourteen months for cancer of the stomach. It is probable therefore, that the patient had his carcinoma before he was injured.

The same is true of the woman, aged 62. Being injured in August 1932, she showed symptoms of her neoplasm in October and, as reported, the exploratory operation showed an extensive carcinoma of the ovary already present. No figures have been found on carcinoma of the ovary, but clinical experience suggests that in the beginning these growths are fairly slow and a number of patients have been known to live two or three years with fairly extensive neoplasms of this type. Again, the conclusion is justifiable that the mental shock could have nothing to do with the inception of the disease.

It is possible, of course, that worry and mental depression might lead a patient to irregular eating or to the neglect of the care of the bowels, which over a prolonged period may induce chronic gastric or rectal lesions on which a cancer might ultimately develop, but this is purely a theoretical assumption, and cancer in general afflicts both the robust and the feeble. Recent figures from the Metropolitan Life Insurance Company have even shown that those with overweight have a significantly higher cancer rate than those with underweight.

The paper by Marullaz is concerned largely with generalizations drawn purely from results obtained from the production of tumors by tar painting in animals, the effect of trauma, and the possible correlation between these conditions and that of the peripheral nerves. Marullaz thinks that the ease with which epitheliomas are produced by painting the ear of the rabbit depends on the special innervation of the ear, because painting the rabbit elsewhere does not produce tumors with the same speed. This cannot be considered a valid argument, the paper is diffuse and largely speculative.

AMENORRHEA

To the Editor—I have under my care a girl aged 18 years who has not menstruated for a year and a half. She started to menstruate at the age of 11 and continued until she was 16. The menstrual course lasted four days, was normal in amount and came every twenty-eight days. The girl apparently is perfectly healthy. She is stockily built but is not fat. She has normal appearing breast. Her genital organs are normal to palpation and inspection. Is it possible for a girl of this age to have a menopause? Can you assign any other reason for this stoppage of her menstrual cycle? Please omit name.

M D, Montana

ANSWER—The absence of menstruation, especially in a young woman, does not mean that the woman is in the menopause, because amenorrhea is only one symptom of the climacterium. True, it is the most prominent clinical phenomenon, but it is not the only one. It is unusual for a woman to undergo true change of life before the age of 35. In temperate zones about 50 per cent of women experience the climacterium between 45 and 50 years of age, and an additional 25 per cent have it between the fortieth and forty-fifth year.

It is possible that this case may be one of the rare cases of very early menopause, but it is more likely that it is a case of secondary amenorrhea. The cause may not be easy to find. Among the usual etiologic factors in secondary amenorrhea are change of climate, defective health, acute infectious diseases, nervous disorders and constitutional diseases such as pulmonary tuberculosis, anemia and diabetes. In many instances secondary amenorrhea is associated with obesity, and in such cases both the amenorrhea and the obesity have a common cause, namely, some disturbance in the glands of internal secretion. Even when there is no obesity, most cases of secondary amenorrhea result from an aberration in the function of one or more ductless glands. The glands usually involved are the pituitary, the ovaries and the thyroid. It is usually difficult to detect the responsible one. It is advisable to perform the Frank test for sex hormones to see if there is a periodic sex cycle.

The absence of menstruation per se is not anything to be alarmed about. The patient and her parents should be told that the general health in such cases is generally as good as that of menstruating women. If the Frank test demonstrates a sex cycle the patient's chances for a return of the monthly flow and for becoming pregnant are good. If there is no sex cycle the prognosis for these occurrences is doubtful.

HYDATID MOLE

To the Editor—A primipara aged 21, whose last menses occurred Oct 15, 1933, states that severe pains began Dec 10 1933 together with the discharge of large clots but no fetus or membranes. The patient was put to bed but the bleeding was markedly subdued and the pains ceased Jan 7 1934 in spite of absolute rest and medication, quite a severe bleeding with the expulsion of large clots was experienced. I then instituted measures to terminate the pregnancy with the result that no fetus was found in spite of the delivery of a placenta the size of a 3 pint jar. This consisted of a very friable structure composed of 'cells' having the appearance of Tokay grapes varying in size from 2 by 1 cm down to microscopic structures of the same consistency and appearance. The supporting structures were very fragile and would break under the slightest traction. The 'cells' were filled with a watery fluid. I have been unable to find anything in books or the literature that describes such a placenta nor did the consultant ever see anything do not publish my name.

M D, Texas

ANSWER—This was apparently a case of hydatid mole, also known as vesicular mole, the most common form of abnormal chorionic growth. The products of conception in such cases present a rounded mass more or less covered with grapelike translucent vesicular clusters of abnormal chorionic cells. In well developed cases, a fetus is usually not present.

There may be only a few vesicles, barely sufficient to warrant a diagnosis of hydatid. Such partial vesicular degeneration is frequently found in aborted ova.

The pathologic process consists in atypical rapid growth of the villous epithelium, with associated degenerative changes in which the cells undergo vesicular swelling. The placenta may disappear, the fetus more or less completely degenerate. Microscopic examination reveals that the individual cysts consist of swollen and edematous chorionic villi, the covering composed of proliferated Langhans cells and syncytium.

The etiology of this condition is still in doubt. Lesser degrees of hydatid degeneration are exceedingly frequent, but typical hydatid moles are relatively rare. The frequent incidence of lutein cysts of the ovary in cases of hydatidiform mole is well recognized.

The diagnosis of hydatid mole can be established with certainty only by passage of the mole. Yet bleeding in the early months of pregnancy together with disproportionate enlargement of the uterus and a positive Aschheim-Zondek test with greatly diluted urine is strongly suggestive. Mazer and Goldstein advocate use of only 1 cc of the patient's urine, which is diluted twelve times and injected into an isolated rabbit.

Patients who give birth to ova with lesser degenerative changes require no treatment other than continued observation. The passage of a typical hydatid mole is an indication for great watchfulness over a period of many years. Subsequent inexplicable bleeding suggests the possibility of a chorioepithelioma and is an absolute indication for careful investigation of the uterine contents. Hysterotomy may then be preferable to simple diagnostic curettage. Schumann favors hysterectomy in the more serious cases, but most authorities believe that removal of the uterus should be reserved for those instances in which there is definite evidence of a malignant condition.

DANGERS OF REPEATED SPINAL ANESTHESIA

To the Editor—Can the injection of procaine hydrochloride into the spinal canal (spinal anesthesia) be repeated at close intervals (say from four to five hours apart)? I am asking this question with specific regard to its therapeutic or prophylactic value in treating or preventing shock especially when shock is the result of abdominal injury. Please like it. Please omit name.

M D, Nebraska

ANSWER—There are cases on record in which spinal anesthesia has been repeated at short intervals without producing any unusual symptoms or causing any apparent damage (Sullivan, W M. Observations on a Patient to Whom Spinal Anesthesia was Administered Five Times Within Thirty-Eight Hours, *THE JOURNAL*, Sept 17, 1932, p 993). The procedure is not without danger. As shown by Davis, Havens, Givens and Emmett (Effects of Spinal Anesthetics on the Spinal Cord and Its Membranes, *THE JOURNAL*, Dec 12, 1931, p 1781) the spinal anesthetics in general use today have a myelolytic action on the nerve structures. In an experimental study they observed varying degrees of inflammatory reaction of the leptomeninges, passive changes in the ganglion cells of the gray matter of the spinal cord, swelling and fragmentation of the axis cylinders, and signs of degeneration of the fiber tracts of the cord. These changes were more pronounced with the larger doses. Repeated doses of a spinal anesthetic at short intervals may possibly cause an irreversible damage to the nerve structure and severe inflammatory reaction, with subsequent formation of scar tissue in the leptomeninges. There is likewise danger of an intoxication from the anesthetic drug itself from the possible accumulative effect of the repeated

doses at short intervals. The use of spinal anesthesia in the treatment and prevention of shock following an abdominal injury is a dangerous procedure. One of the manifestations of shock is a low blood pressure. Spinal anesthesia, because of its effect in lowering the vascular tone of the blood vessels, may lead to a splanchnic dilatation and a pronounced fall in blood pressure. The danger of further lowering the blood pressure of a patient in shock, following an abdominal injury, is a definite contraindication to the use of spinal anesthesia.

HIGH CARBOHYDRATE AND HYPERINSULINISM— DEXTROSE IN FURUNCULOSIS

To the Editor—In several recent articles on hyperinsulinism low carbohydrate diets have been advocated to prevent hypoglycemic reactions. Please explain the action of this diet as compared with one high in carbohydrates to utilize the excess amount of insulin. 2 Some time ago I read an article advocating the use of intravenous dextrose in the treatment of chronic cases of furunculosis. Do you know of any definite basis for this treatment and is it generally accepted? Could you supply any references? Kindly omit name.

M D, West Virginia

ANSWER—1 High carbohydrate diets have been given in cases of hyperinsulinism with the view of combating the obvious immediate cause of symptoms, i. e., the hypoglycemia. However, it is generally considered that the ingestion of carbohydrate stimulates the normal pancreas to secrete insulin, which is necessary for the disposal of the sugar. From this point of view, although the carbohydrate temporarily corrects the hypoglycemia it may also aggravate the underlying condition by stimulating the already overacting pancreas to still further secretion of insulin. The recent attempts at treatment of hyperinsulinism with low carbohydrate diets have been directed at this theoretically more fundamental mechanism. The purpose here is to remove the stimulus from an organ which is supposed to be hypersensitive to it (Shepardson, H C *Endocrinology* 16 182 [March-April] 1932).

2 Chronic furunculosis has been treated with intravenous injection of dextrose solution and high carbohydrate diets by Tauber (*Arch Dermat & Syph* 27 198 [Feb] 1933). The treatment was based on the study of blood determinations in more than 1,500 cases, 511 of which were dermatologic. His observations were not in accord with the general belief that skin disorders are commonly associated with hyperglycemia. He found most of the blood sugars to be normal, and the values in furunculosis to be low as a rule.

Tauber's observations and results are striking and must be given serious consideration. The treatment he suggests can hardly be said to be generally accepted as yet. For an example of opposing views the reader is referred to the work of J H P Paton (*Brit M J* 1 738 [April 29] 1933).

TREATMENT OF SCLERODERMA

To the Editor—I have a patient a man aged 53 who is suffering from atrophic arthritis. Within the past six months there has developed a rather generalized scleroderma associated with Raynaud's syndrome. All foci of infection have been removed and a rather badly infected pair of tonsils were enucleated about six months ago. Treatment for the arthritic condition has included dietary regulation, vaccine, hydrotherapy and physical therapy and although the basal metabolic rate was found normal on three occasions he was given thyroid extract empirically for the past month with distinct improvement in his arthritic as well as the skin condition. I should like to know whether you can suggest something that would hasten the improvement in his skin condition. I read somewhere that pancreatin is beneficial in scleroderma and should like to know how it is used in this condition. Could you also give me any references on the subject? Please omit name.

M D, Arkansas

ANSWER—The treatment of scleroderma is fraught with many difficulties. Perhaps the treatment that has proved most satisfactory is massage and hydrotherapy. Thyroid extract is the next most useful remedy. Injections of milk and other forms of nonspecific protein therapy have been recommended but have not in general been useful. Brown, O Leary and Adson have resected the sympathetic ganglions in selected cases. O Michaelis (*Brussels med* 9 560 [March 17] 1929) suggested the use of insulin and Seller (*Munchen med Wchnschr* 79 1625 [Oct 7] 1932) states that he has had some benefit from the use of pancreas extracts. The articles by Lewin and Heller (*Charite-ann* 19 763, 1894), Cassirer (*Die vasomotorisch tropischen Neurosen*, ed 2, Berlin, 1912), Osler (*J Gen-Urn & Skin Dis* 16 49, 127, 1898), Castle (*Brit J Dermat* 35 255 [July] 303 [Aug-Sept] 1923) and Brown, O Leary and Adson (*Ann Int Med* 4 531 [Dec] 1930) give considerable information concerning the disease.

SEQUELAE TO OVARECTOMY

To the Editor—A well nourished woman aged 29, was operated on for the removal of a small fibroid both ovaries and the appendix one year ago. Six months after the operation and during the customary time for the menstrual period she began to complain of pain in the back. This pain lasts about a week and is followed with a spell of hiccups. The time for the next period begins with a pain in the lower part of the abdomen which lasts for a week. Severe headache marks the beginning of the next period. Each attack is followed by hiccups forty five or fifty a minute. This has been the condition for four or five months resisting all ordinary sedatives. The blood pressure is 120 systolic 80 diastolic. The red blood cells number 2 786 000, white cells 4 700, hemoglobin is 50 per cent. Two years ago the patient received eighteen injections of neosarsphenamine and eighteen of a bismuth compound. The spinal fluid test is negative. Will you please advise me what is causing the condition? Please omit name and address.

M D Missouri

ANSWER—The distressing conditions from which the patient suffers illustrates once more the fact that, when one removes the ovaries in a young woman, serious trouble may follow. Gynecologists are agreed that ovarian function is essential to the well being of most women, and removal of both ovaries should be avoided so far as possible. This is particularly important if the woman has an instability of the nervous system or evidence of a dysfunction of various organs of internal secretion. While this incomplete history suggests an element of hysteria, there must be some physical reason for the anemia and low leukocyte count. The nature of the anemia should be determined and the condition corrected as an essential part of the treatment. A basal metabolic test is desirable, since hypothyroidism may be present and the patient may need thyroid medication.

It is stated that she does not secure any relief from the ordinary sedatives and one may wonder which drugs have been tried. Recent studies indicate that certain individuals have an idiosyncrasy for phenobarbital and the group of drugs containing amidopyrine and it is possible that the low leukocyte count may have resulted from the use of this group of drugs. This possibility should be investigated.

Patients of this type appear to be benefited at times from the use of theelin injections or from the use of the vaginal suppositories of amniotin. However on the whole, more can be expected from the use of small doses of thyroid by mouth.

FLUORINE MOTTLED ENAMEL AND SENILE DENTAL DECAY

To the Editor—A man aged 54 for the past eight years has been suffering a progressive loss of the enamel of his teeth. The beginning of this loss was approximately three months after he changed his residence and received his water supply from the same source but a different reservoir. I sent for an analysis of the water and find that it contains four parts of fluorine per million. For the last three years the condition has become stationary, but the dentin is almost everywhere exposed. Physical examination shows a hypertension with the blood pressure varying from 140 to 190 systolic. The functional kidney test, blood non-protein nitrogen, calcium and phosphorus are normal. He has a beginning hepatic cirrhosis as indicated by a slightly enlarged liver. The galactose tolerance test and indirect van den Bergh test are positive. The icterus index is 142. Repeated hemorrhage is probably from esophageal varices as roentgenograms of the gastrointestinal tract and lungs show nothing abnormal. I should be interested to know whether the fluorine content of the water is your account of this condition or whether some other cause should be searched for.

FRED S. MODERN, M.D., Los Angeles

ANSWER—Fluorine in the amount of four parts per million in the drinking water is ample to produce mottled enamel in developing teeth, but such teeth after eruption, if anything, are more resistant to dental decay and enamel destruction than the teeth of subjects who have not been exposed to the effect of fluorine. It is stated that even as little as 0.1 mg of fluorine per kilogram of body weight taken by mouth daily may produce the symptoms of chronic fluorine poisoning, such as loss of weight, loss of appetite, cachexia and brittle bones, and this is in the lower range of what will cause mottled enamel. No other effects of chronic fluorine poisoning are listed (DeEds, Floyd, *Chronic Fluorine Poisoning, Medicine* 12 1 [Feb] 1933). The mouth conditions in this case although incompletely described, do not at all resemble those found in the teeth of persons residing in mottled enamel districts. They bear a much greater resemblance to what is known as senile decay, a form of dental decay that is greatly aggravated by various types of degenerative disease. Under such conditions even resorption of the tooth roots may take place (Mueller, Emie, and Rony, H R, *Unusual Case of Resorption J Am Dent A* 17 326 [Feb] 1930). Consequently one is forced to the conclusion that the mouth conditions in this man are in part secondary to his systemic disease and that the fluorine in the water supply is without etiologic significance.

INDUSTRIAL HAZARDS OF WORKERS WITH
HOT PARAFFIN

To the Editor—Will you please give me an opinion as to whether any health hazard actually exists in the following situation. The company has been informed that no change is required legally but it will try to eliminate the hazard if it exists. Certain workmen spend their full working time with hot paraffin. There are nine tanks of the paraffin, approximately 2 by 3 feet. The paraffin is heated to about 255 by steam under 20 pounds pressure. These tanks are located in a room measuring 40 by 100 feet with no induced ventilation and poor natural ventilation. There is vapor rising from these tanks and a very definite odor from the hot paraffin. Can one consider that the lungs of these workmen suffer any ill effects from the rather constant exposure during their working period. Please omit name. M D, Pennsylvania

ANSWER—The ill effects likely to develop after exposure to the conditions described are those associated with general unhygienic work conditions rather than with any specific action of paraffin or other coal tar or petroleum derivatives associated with the paraffin. Without any artificial ventilation and with only poor natural ventilation, it seems likely that this workroom may become highly overheated, at least in summer, possibly the humidity will reach excessive percentages, odors from paraffin will give rise to nausea and to shallowness in breathing. Paraffin fumes may serve as a minor irritant to the eyes and respiratory tract. The work effectivity, the general health and the comfort of the workers exposed to these conditions will be impaired. Even in the absence of a specific occupational disease hazard it appears desirable that conditions of this character be rectified.

DIFFERENTIAL DIAGNOSIS OF BRAIN TUMOR AND
OTHER DISTURBANCES

To the Editor—A girl aged 5 years had an attack of vomiting about two months ago which subsided in one day after the intake of a little phenyl salicylate and lismuth. A month later the child who had been perfectly normal except for a temperamental anorexia was brought into the office having developed in the preceding three weeks a peculiar gait. Physical examination shows a rather poorly nourished girl who is irritable and extremely hard to examine. She walks with a lordosis and typical toe drop gait. On arising from the floor she climbs up on herself as in muscular dystrophy. The knee jerks and ankle jerks can not be elicited. A moderate atrophy is symmetrically distributed. Nose and throat cultures are negative. The stools are normal. There are no obvious foci of infection. Roentgenograms of the skull showed nothing unusual. Films of the long bones showed no evidence of lead. The blood shows 70 per cent hemoglobin and 4 620 000 red cells. There is no stippling of the red cells. Examination of the spinal fluid showed a clear fluid with normal pressure. The cell count is zero. There is a 3 plus globulin and a total protein of 185 mg per hundred cubic centimeters. The Wassermann reaction of the blood and of the spinal fluid was negative as was the tuberculin test. Is there anything further you can suggest to establish a definite diagnosis and presumptive treatment. The child is very much spoiled and cries a dozen times daily purely for attention and I feel that no small part of her condition is made up of the proverbial *malade imaginaire* and the supercare of the parents. But the case is at a standstill. What do you advise? Please omit name. M D, Massachusetts

ANSWER—The data presented in the query are not sufficient to permit attempting a definite diagnosis. From the symptoms enumerated, one would surmise that there was a disease of the brain.

The points noted in the examination of the child, such as a peculiar gait, extreme irritability and lordosis with toe drop gait, as well as absent knee jerks and ankle jerks, and a moderate atrophy of the muscles, indicate an organic nervous disease.

A three plus globulin and a total protein of 185 mg per hundred cubic centimeters in the spinal fluid are of pathologic significance. It should be recalled that the amount of protein normally present in the lumbar fluid varies between 15 and 45 mg per hundred cubic centimeters of fluid. It may also be noted that globulin does not exist in demonstrable quantities in the normal cerebrospinal fluid of infants and young children and that when a definite globulin test is present the fluid should be considered pathologic. While examining the spinal fluid it would be well to make a quantitative sugar examination. A low sugar content would speak for meningitis. A normal or high sugar content would suggest encephalitis or brain tumor.

In this particular child a detailed neurologic examination should be made including a careful inspection of the eye grounds. An attempt should be made to elicit the more familiar neurologic tests—the Babinski, Brudzinski and Oppenheim signs should be searched for.

The gait should be tested to elicit ataxia or cerebellar gait. The cranial nerves should be tested for abnormal functions. Such questions as these require solution in arriving at a diagnosis in this case.

May the child have a brain tumor in process of formation? May she have a slowly progressing tuberculous meningitis?

Could she possibly be suffering from postencephalitis symptoms? Have postdiphtheritic neuritis and botulism been fully excluded?

An examination conducted along these lines may clear up the diagnosis.

OBESITY WITH WATER RETENTION

To the Editor—May I have your suggestions for therapy in the following case of obesity. A married woman aged 42, weighs 215 pounds (97.5 Kg). The menstrual periods are regular. Three children are living, one of whom has inherited the same type of obesity. There have been no serious past illnesses. The patient has had three miscarriages. She has been on a restricted although varied, diet and has been taking desiccated thyroid for the past six months with loss of only a few pounds. She was placed on thyroid because of extreme constipation and sparsity of the hair and eyebrows. An outstanding symptom and I believe the cause of her obesity lies in the fact that she drinks large quantities of water daily—as much as 2 gallons—but there is no polyuria. Examination of the urine is negative for sugar. Please omit name.

M D, New York

ANSWER—It is presumed from the data given that this is a case of constitutional obesity and that the patient has been overweight from childhood. A tendency to retain water is encountered in many cases of obesity. The subject is discussed extensively by von Noorden (*Die Fettsucht*, ed 2, Leipzig, 1910) and was recently considered by Rowntree and Brunsting (*Water or Fat? Water Retention in So-Called Endocrine Obesity*, *Endocrinology* 17:377 [July-Aug] 1933), who saw some benefit from the use of diuretic measures. One cause of water retention in the obese is relative cardiac insufficiency. Wilder has discussed this in a paper which contains therapeutic suggestions for obesity (*The Treatment of Obesity*, *Internal Clin* 4:1 [Dec] 1933).

MEASUREMENT OF LOSS OF VISION

To the Editor—I have recently examined a patient for an industrial injury of the left eye. The question that I wish to ask is: What percentage of visual deficiency would one estimate the patient to have suffered? There is no history of previous ocular disturbance. Several days previously he was struck in the left eye with a steel bolt. There is no disturbance of motility. Central vision uncorrected is right eye 6/5, left eye 6/25. The right eye is normal in all respects. The left eye shows a dilated immobile pupil. There is a slight iridodonesis in the lower outer quadrant. The crystalline lens is clear. There is no disturbance of the vitreous body or of the fundus. A visual field test shows a scotoma at the central point. A 3 mm test object was used at a distance of 1 meter. There is contraction of the peripheral field 50 degrees above 40 degrees down, 40 degrees in 35 degrees out. The refraction of each eye discloses a low compound hyperopia. The corrected vision of the left eye is 6/10. With a pinhole disk the vision is not quite equal to 6/6. The use of a miotic drug in the left eye that will contract the pupil to the same size as the right pupil produces a much greater total astigmatism. I believe that the patient has suffered a laceration of the suspensory ligament of the lens in the lower outer quadrant which permits a twisted position of the lens with irregular astigmatism. What is a reasonable estimate of the visual impairment of this patient? Please omit name.

M D, Indiana

ANSWER—Estimates of visual loss are of course based for the most part on the loss of central and stereoscopic vision and marked restriction of the temporal field. With both eyes in use, the patient would note a limitation of his ability to see things coming from his left side and possibly would still see objects of some size in this field. There can be no estimate of loss that is at all exact in such a case but the loss is perhaps as little as 5 per cent and not more than 15 per cent.

ABSORPTION BY RECTUM

To the Editor—I should like to have information regarding the absorption of foods and drugs by rectum. The main ones are dextrose, sodium bicarbonate, quinine and sedatives. If this is not asking too much I should also like to have a list of foods and drugs that are susceptible of absorption by rectum and also the degree or percentage of food or drug that is absorbed. Please omit name and town. M D, Florida

ANSWER—Water, certain salts and volatile agents in general are the only substances that are satisfactorily absorbed from the rectum. This means that, besides water, such salts as sodium chloride, sodium bromide and sodium bicarbonate as well as alkaloidal salts such as morphine sulphate or atropine sulphate and volatile agents such as ether or paraldehyde in oil, or alcohol or chloral in aqueous solution can be administered by the rectum with expectancy of therapeutic results. Quinine is too irritative to be tolerated in sufficient dosage by the rectum for adequate systemic action. It has been shown that dextrose and other nutrients are not sufficiently absorbed for practical purposes of nutrition. In other words, that 'rectal feeding' is a delusion and a snare.

HOSPITALIZATION AFTER HYSTERECTOMY

To the Editor—Please advise me how many days a patient should be hospitalized after a hysterectomy (subtotal) for an uncomplicated fibroma uteri. When is it safe to discharge such patients and place them under the family physician? Kindly omit name.

M D, District of Columbia

ANSWER—Two weeks should be ample unless there are complications. Many patients are sufficiently recovered to leave the hospital in ten or twelve days.

As a rule, after pelvic operations performed by the abdominal route patients may appropriately be permitted to resume activities when they feel physically able. For example, out of bed on the fourth or fifth day, or perhaps not until the eighth or ninth day if the effort is too great. Return home may be permitted even before the patient walks, provided there is a feeling of well being and there are no complications. She should be urged to avoid bumping and jolting and physical efforts that produce discomfort or fatigue. If the patient can be impressed that she should do what nature tells her to and not what her ambitions prompt her to attempt she may be placed under the care of the family physician immediately on leaving the hospital. The surgeon should see the patient again after a few weeks, and preferably two or three times more during the ensuing months, until the health is normal.

USE OF X RAYS ON SALIVARY GLANDS

To the Editor—In the case of excessive salivation due to paralysis agitans what are the dangers and what are the good results of treating this condition with x rays? Are the x rays applied to the gland or to the nerve? Is there any destruction of tissue intended or desired? Please omit name, town and state.

M D California

ANSWER—Treatment of the salivation due to paralysis agitans by radiation is a highly experimental procedure. It is a common experience of radiologists in treating tumors in the region of the jaw and neck to have the patients develop dryness of the mouth and of this they complain greatly. It is probable that many patients would find such relief more distressing than the symptom itself for it is impossible to regulate the dosage so as to obtain an intermediate effect between hypersecretion and suppression of secretion. Moreover the relief obtained is only temporary, even with strong dosage. The irradiating is done over the entire gland region. It is not known whether the effect is obtained from the gland or from its innervation. Treatment sufficiently strong to produce actual destruction of gland tissue would be neither desirable nor safe.

ACUTE NEPHRITIS AFTER IMPETIGO

To the Editor—My question concerns a youth of 17 years of robust type who has had an impetigo vulgaris for some months. He then contracted bronchopneumonia of the influenza type. In one week he died. Nephritis developed during the last three days of life. During the last day of life the urine contained 2 per cent albumin. Some of the impetigo patches below the lower jaw had taken on an ecthymalike character during the last two weeks that he lived and were the sites of extensive pus pockets for some days before he died. Just how important must impetigo and ecthyma be considered? Were they probably in this case the real cause of the attack of nephritis? Please omit name and town.

M D Minnesota

ANSWER—From the evidence, it would seem that the patient developed acute nephritis. The most frequent cause of acute nephritis is infection, particularly with organisms of the streptococcus group. Most probably streptococci were present in the skin lesion, and the skin lesion in that sense represents the source of the infection that resulted in acute nephritis. There probably was no more specific relation than this between the skin lesions and the nephritis. The bronchopneumonia was another possibility of the infection inducing the nephritis.

RESPIRATORY RATE IN INFANTS

To the Editor—I have a patient an infant 1 month old who though normal in all respects as far as appearance, nourishment and weight are concerned, has a respiratory rate of about 100. This varies a little with meals and other activities but is at all times rapid. Kindly advise. Please omit name.

M D, New York

ANSWER—The respiratory rate in new-born infants is more rapid than in the adult, as well as more shallow and less rhythmic. Various tables have been compiled for the respiratory rate in infants and children. The average rate at birth is said to be about 44 per minute, at the end of the first month about 35, at 1 year about 30, and at 5 years about 26.

A respiratory rate of 100 per minute in an infant 1 month of age is definitely abnormal, and search for the cause of the condition should be made. Following birth the infant may have suffered from an aspiration pneumonia and a portion of the lung may be atelectatic. There may be a cerebral condition causing stimulation of the respiratory center in the medulla. A diaphragmatic hernia that allows a portion of the abdominal viscera to extend into the thorax, thus causing compression of the lung, may be another cause of such a compensatory rapid rate.

BONES AND TEETH OF DINOSAURS AND LIZARDS

To the Editor—Kindly tell me whether the leg bones of the dinosaurs are solid also whether if the teeth replace themselves after being removed similar to the replacement of the limb in certain species of lizards.

FRANK E. WIEDEMANN, M D, Terre Haute Ind

ANSWER—In certain groups of dinosaurs the long bones of the legs were solid to the extent that there was spongy bone in the shaft instead of a marrow cavity. This is true of the groups to which the brontosaurus and the great horned dinosaur (Triceratops) belong. In the third group many genera have hollow limb bones.

In all living reptiles (except the toothless forms, such as turtles) numerous generations of teeth are developed and usually there are two parallel ridges (dental laminae) from which the teeth normally arise throughout life. There is clear evidence of similar conditions in many dinosaurs. The regeneration of a lost limb or tail is different in that the new parts do not arise from a persistent embryonic structure like the dental lamina.

SEVERANCE OF NERVES FOR PAIN

To the Editor—Is severance of the saphenous nerve an accepted procedure for intractable pain on the medial aspect of the leg (right)? The patient has a flaccid paralysis of the entire right lower extremity following a fractured spine. Would severance of the sciatic nerve in the popliteal space alleviate painful cramps in the same leg and is this an accepted procedure? Please omit name.

M D Long Island

ANSWER—Severance of the nerve as discussed in the query may destroy forever the patient's only chance of recovery of the muscles supplied by that nerve. Pain may indicate the patient's only opportunity for return of muscle power.

VEHICLE FOR TINCTURE OF STRAMONIUM

To the Editor—Would you suggest that a mixture of syrup of glycyrrhiza and elixir of anise would be a good vehicle for tincture of stramonium? If not what would be the best vehicle?

FLOA McEWEN, M D Newark N J

ANSWER—One could hardly suggest a more pleasant vehicle for tincture of stramonium than the one mentioned unless it be "iso-alcoholic elixir" which would be obtained by a mixture of equal quantities of "aqueous elixir" and of "alcoholic elixir," formulas for which may be found in the *Technic of Medication* by Bernard Fantus published by the American Medical Association. This yields a clear solution, the vehicle being approximately of the same alcoholic strength as the menstruum used in the preparation of tincture of stramonium. The only objection to the vehicle mentioned in the query is that, owing to its strength in alcohol there is some precipitation of ingredients of the tincture of stramonium and, unless the bottle is shaken each time before taking, there may be an inequality in dosage.

GAS GANGRENE ANTITOXIN

To the Editor—Will you kindly give me some information with regard to the status of tetanus gas gangrene antitoxin? Do you recommend this to be given in all cases in which tetanus antitoxin was formerly used or only when it is believed that the wound is infected with the gas forming organisms? The combined antitoxin is more expensive and as a prophylactic measure would you recommend that this be used in the hospital in all cases in which the tetanus antitoxin seemed indicated? Will you also kindly tell me how the incubation period of gas gangrene compares with tetanus?

P F PRIOLEAU, M D Fairmount W Va

ANSWER—Gas gangrene antitoxin needs to be used only when in addition to the tetanus hazard there is judged to be a risk of gas gangrene also. In general, when there is evidence of contamination of the wound with street or farm dirt and crushing or other devitalization of tissue. The incubation period of gas gangrene is ordinarily shorter than that of tetanus—often only two or three days—while that of tetanus is rarely under eight or ten days.

TREATMENT OF OZENA

To the Editor —Please outline the most recent treatment for ozena

A G FELTER M.D., Van Meter Iowa

ANSWER—Attempts have been made in recent years to treat ozena by means of endocrines, on the basis that there is some deficiency in the secretions of certain of the ductless glands. On the other hand, efforts have been directed toward narrowing the air space in the nose by implantation of ivory into the septum, in order to prevent the rapid drying out of secretions, the formation of crusts, and their subsequent decomposition by saprophytes.

Various operations such as the Halle and Lautenschlager, have been devised with the same end in view to diminish the air space by mobilizing the nasal lateral wall and moving it closer to the septum. Since the exact etiology of ozena has never actually been determined, it is quite logical that the methods of treatment have been varied and the results unsatisfactory in many cases.

FISTULA IN ANO

To the Editor—A woman aged 30 years married has had a blind external fistula in ano for the last twelve months. This condition followed an abscess. Her blood was positive for syphilis (4+) and she has had consistent treatment since with injections of neoparsphenamine and bismuth compounds. The fistula was cured once about six months ago but continues to drain. Kindly advise what can be done to heal this condition. Please omit name.

M D New Jersey

ANSWER—It is probable that the abscess originated from a small lesion in the rectum which still persists and which is the internal opening of a fistula. This is most likely to be on the posterior wall of the intestine at the mucocutaneous line. Some of these sinuses are small and require diligent search before they can be found. If such a fistulous tract runs from the old abscess cavity into the rectum this tract must then be laid open into the intestine. It is unlikely that the syphilis has any relationship to this abscess or the persistent fistula.

ADENITIS AFTER TULAREMIA

To the Editor—What method of treatment would you advise for adenitis of the left axilla following tularemia? I recovered from the disease two months ago and since have had a lymph node in the axilla that is perhaps as large as a pigeon egg which gets in my way in using my arm but does not cause pain or discomfort. I have been taking iodides and am wondering whether x-rays or surgery would be indicated. Please omit name.

M D Indiana

ANSWER—Roentgen therapy is apparently of considerable value in hastening resolution of lymphadenopathy in such cases. Simpson and Foshay have found that the antitularense serum developed by Lee Foshay of the University of Cincinnati is effective in overcoming the lymphadenopathy. If neither of these methods should be effective, and if suppuration should occur, surgical incision and drainage would be indicated.

AIR IN PLEURAL SAC

To the Editor—Is there or is there not a minute bit of air within the pleural sac?

THOMAS W BURKE M.D. Houston Texas

ANSWER—In the normal condition the parietal and the visceral pleura are in intimate contact throughout. There is no air present. If a small amount of air is allowed to escape into the pleural cavity during the process of thoracentesis, during which there is a tendency for air to be sucked in, it is promptly absorbed. When therapeutic pneumothorax is used, refills are necessary at frequent intervals to replace the air so absorbed. Unless this is done the pneumothorax disappears completely, unless other conditions are present preventing reexpansion of the lung.

INJECTION OF FOREIGN PROTEIN AND RELAPSE IN MALARIA

To the Editor—Recently I was called to care for a man who was having a violent chill. There was a history of malarial infection about five years previously without relapse in the meantime. Five days preceding the chill he had been given a prophylactic dose of scarlet fever antitoxin when the disease broke out in his family. The diagnosis is definitely malarial relapse, the infection being tertian. May the antitoxin have been the exciting cause of the relapse? Please omit name.

M D Minnesota

ANSWER—In both human and simian malaria foreign protein or serum is known to precipitate relapses in some cases. It seems probable therefore that the antitoxin was the exciting cause in the present case.

Vermont February Examination

Dr W Scott Nay, secretary, Vermont State Board of Medical Registration reports the written examination held in Burlington, Feb 7-9 1934. The examination covered 12 subjects and included 90 questions. An average of 75 per cent was required to pass. Seven candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Georgetown University School of Medicine		(1931)	86.1
Tufts College Medical School		(1933) \$1.4	91.6
University of Vermont College of Medicine		(1930)	88.1
(1933) \$0.2 \$2.3			
University of Montreal Faculty of Medicine		(1935)	83.5

Book Notices

New and Nonofficial Remedies 1934 Containing Descriptions of the Articles which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1 1934. Cloth Price \$1.50 Pp 510 Chicago American Medical Association 1934

"Is it in N N R?" This question is being increasingly asked by physicians concerning the preparations offered by manufacturers of pharmaceuticals. Recent decisions on the part of certain relief agencies that only Council-accepted preparations would be used in their medical activities has promoted interest in this book and in the actions of the Council, which it represents, especially on the part of manufacturers of pharmaceutical preparations. It may be a utopian wish, but one would like to envisage an era in which all physicians and manufacturers were to adopt the high ideals of rational therapeutics for which the Council stands. The names of the present membership of the Council and of the past year's consultants are representative of the best and most enlightened thought in the medical field.

New and Nonofficial Remedies, 1934, has the same format that has characterized it in past years. The enrichment of the indexing begun a few years ago, is continued and its value even increased by some desirable simplification of cross references.

The lists, appearing in the preface, of omitted products and of changes in the descriptions of retained products, as well as the references to textual changes in general articles under which individual preparations are classified, give indication of the care with which the Council makes the annual revision of the book. The general article Lactic Acid-Producing Organisms and Preparations has been practically rewritten. The chapter on arsenic preparations has undergone some revision, especially in the statement concerning neoarsphenamine. The descriptions of chiniofon and viofilm have been revised in the light of recent developments in the treatment of amebiasis. The article on ethylhydrocupreine has been revised to delete reference to optochin base, which has been omitted, optochin hydrochloride has been retained, being recommended only for external use. The description of typhoid vaccine has been revised to give the dosage of the combination of typhoid and paratyphoid organisms and to mention the use of typhoid vaccine in nonspecific protein therapy. A number of revisions of the Council's rules have been made, particularly with reference to the names of products which is one of the most frequent and troublesome of the problems with which the Council has to deal. Revisions of more or less importance occur in the following chapters: Antimeningococcic Serum, Antipneumococcic Serum, Arsenic Compounds, The Azo Dyes, Barbitol and Barbitol Compounds, Bismuth Compounds, Bromine Derivatives, Chloral Derivatives and Substitutes, Cinchophen and Cinchophen Derivatives, Creosote and Guaiacol Compounds, Digitalis Principles and Preparations, Diphtheria Immunity Test (Schick Test), Diphtheria Toxin-Antitoxin Mixture, Ephedrine, Epinephrine and Epinephrine Preparations, Ergot, Erysipelas Antistreptococcic Serum, Erysipelas and Prodigiosus Toxins (Coley), Ethylhydrocupreine, Lactic Acid-Producing Organisms and Preparations, Mercury and Mercury Compounds, New Tuberculin B E, New Tuberculin B E Dried, New Tuberculin-T R, New Tuberculin T R Dried, Pituitary Gland, Rabies Vaccine, Radium and Radium Salts, Scarlet Fever Immunity Test, Scarlet Fever Streptococcus Antitoxin, Scarlet Fever Streptococcus Toxin, Scopolamine Sensitized Bacterial Vaccines—Serobacterins, Serums and Vaccines, Silver Lactate, Tannic Acid Derivatives, Thyroxin, Tuberculin-Koch, and Typhoid Vaccine.

Among the preparations newly included in this volume are: Aminophylline, a double salt or mixture of theophylline and ethylenediamine with the advantage of greater solubility over other theophylline preparations; the new alum precipitated diphtheria toxoid Neo-Iopax, a new medium for intravenous urography; Benzadrine, an ephedrine substitute; serums containing type II pneumococcus antibodies, which the Council has recently recognized as worthy of clinical trial in view of improved preparations and technique; Autolyzed Liver Concentrate and Extralin, two new liver preparations for use in the

treatment of pernicious anemia, Metycaine, a new local anesthetic, and Sodium Morrhuate, a salt of the fatty acids of cod liver oil, proposed for use as a sclerosing agent

Medizinische Kolloidlehre Herausgegeben von Prof Dr L Liehtwitz
Dr Dr Ralph Ed Liesegang und Prof Dr Karl Spiro Direktor des
Physiologisch Chemischen Instituts der Universität Basel Lieferung 9
Paper Price 5 marks Pp 609 688 Dresden & Leipzig Theodor Steh-
kopf 1933

In this instalment, Gundo Boehm takes up the disclosures of colloid chemistry as regards muscle. These studies make it evident that the myosin exists in the form of threadlike particles, or myofibrils, whose width is less than 1 millimicron and length greater than 500 millimicrons and of a particle weight of approximately 1,000,000. These colloidal molecules, so greatly deviating from the spherical, are arranged in the form of chains and by somewhat approaching the spherical shape are capable of exerting, in their totality, the manifestations of external force characteristic of muscle contraction. Heart as well as involuntary musculature is also composed of a fibrillary structure. It is an interesting fact that the muscles, next to the skin and subcutaneous tissue, are the most important protective organs against alterations in the water content of the system. They contain almost half the total water of the body and because of this are capable of yielding to and abstracting from the system more water than any other organ with but slight alterations in the percentage of water contained in them. Thus far, colloid chemistry has not contributed much to the understanding of the pharmacology of muscles and vice versa, though great revelations may be expected in the future. In the discussion of the colloid chemistry of digestion R. E. Liesegang summarizes the "art of solution" as practiced by the gastro-intestinal tract as maximal addition of water and minimal secretion of salts and that of ions of maximum swelling capacity, repeated change of reaction (for the pepsin to react with positively charged and the trypsin with negatively laden protein ions) and great lowering of surface tension (through bile). The puzzle of the secretion of hydrochloric acid from the alkaline blood is solved at least partly by the demonstration of irreciprocal permeability and a great permeation of Cl^- with slight penetration of Na^+ ions through the gastric mucosa. Osmosis and diffusion do not suffice to explain absorption. Essential, therefore, is the recognition of the pumping action of the villi as well as immediate synthesis into nondiffusible molecules within the cells of the intestinal mucosa. This is especially true of fat. In addition, intestinal peristalsis furnishes filtration pressure.

De Venarum Ostiis 1603 of Hieronymus Fabricius de Aquapendente 1537? 1619? Facsimile edition with introduction translation and notes by A. J. Franklin D.M. Tutor and Lecturer in Physiology of Oriel College Oxford Cloth Price \$3 Pp 98 with 15 illustrations Springfield Ill & Baltimore Md Charles C Thomas 1933

Fabricius was the precursor and teacher of Harvey so his life, work and character will always be of interest to medical men. His study of the valves of the veins is especially interesting, because their study led directly to Harvey's great deduction and proof of the circulation of the blood. Franklin gives a reproduction of the Latin text of Fabricius's paper (1603), a literal translation of it, facsimiles of the eight original plates, an excellent short account of Fabricius's colorful life, an illustrated account of the famous old anatomy theater in Padua built under the direction of Fabricius, an account of the early work on valves and veins, and a reproduction of the first published illustration of them taken from a paper of Salomon Alberti, who studied under Fabricius. A good portrait constitutes the frontispiece and a picture of the statue erected to him in his native city of Aquapendente (Aucula) attests the honor paid him in his own country. The title is interesting especially "ostiola," which he uses for the valves. This term has been used by anatomists at various times, especially for the valves of the heart. Franklin gives an interesting explanation of this fact. Apparently the term was used by irrigation engineers of the time and it is translated by John Browne as "flood gates." Fabricius did not see that they were really valves; he was too much under the influence of Galen's physiologic theory. Fabricius had a picturesquely assertive character, but the intellectual power, courage and independence of Harvey

were required to see the real character and significance of these structures. The biography is delightful. Fabricius was a research man, an anatomist, a surgeon and a physician. His long life of eighty-six years was full of interest. He was naive, forceful, temperamental, quarrelsome, successful. He usually had a lawsuit in process with some one. He lectured sometimes marvelously well, sometimes wretchedly. He began to teach on a salary of \$160 a year. At his death he had \$200,000 and the admiration and love of his contemporaries, even of those with whom he had quarreled. The book throws a clear and interesting light on a plastic period of medical development that gave color and character to modern medical science. Publication in 1933 is timely. Fabricius was born in 1533.

Textbook of Physical Therapy By Heinrich F. Wolf M.D. Chief of the Department of Physical Therapy Mt. Sinai Hospital and Dispensary New York. With a foreword by Lewellys F. Barker M.D. LL.D. Chapters by William Bierman M.D. Director of Physical Therapy Beth Israel Hospital New York. Adolph A. Lillen M.D. Associate Physical Therapist Mt. Sinai Hospital. Farel Jouard M.D. Adjunct Physical Therapist Mt. Sinai Hospital. Madge C. L. McGuinness A.B. M.D. Chief of Clinic Department of Physical Therapy Vanderbilt Clinic New York. Cloth Price \$5.50 Pp 409 with 54 illustrations. New York and London D. Appleton Century Company, Inc. 1933.

This book, besides being comprehensive in scope, introduces an originality of exposition both new and timely in relation to certain discussions of physical therapy topics. It calls attention to unscientific precedents which have developed abusive methods of practice. Written in the style of the iconoclast addressing himself in flexible dialectics, the author presents a picture of a practice inconsistent with scientific medicine and points out the method of its eradication. Specifically, this work is a sharp departure from existing textbooks that stress technics of application and prescriptions for treatment of various pathologic conditions. The author contends that "physical therapy is a specialty like any other. Its practice requires not only a large number of appliances, but special training in the technic as well as its indications." The pivotal point in every specialty is diagnosis and this no less in physical therapy. Attention is directed to the dangers of routine procedures, the absurdity, and inefficiency of which is partly illustrated by the "routine followed by the spas, where nearly every patient was treated according to one rule." Instead of trying to adjust the patient to the treatment, the author advocates adjusting the treatment to the patient. Under the methods cited, it was inevitable that a reaction should follow the naive claims of the early preceptors of physical therapy. This work therefore justifies its *raison d'être* by attempting to place its discipline on physiologic principles. It reduces the uncertainty of empirical practice by the constant stressing of the scientific method and its practical application. The author therefore offers a conservative, comprehensive review of the theory and principles of physical therapy, incorporating concise discussions of every phase of its practice. The several chapters by Bierman, McGuinness, Lillen and Jouard, dealing with hyperthermia and minor electrosurgery, physical therapy in gynecology, diseases of the lower respiratory tract, and otolaryngology, give to this contribution the balance so desirable for student and practitioner. The generous praise of Lewellys F. Barker is readily understood when he says in his foreword that "Dr. Wolf has sifted his material carefully, attempting to eliminate all antiquated methods, but giving the data necessary for individualization of treatment and for the avoidance of crude empiricism in this field."

Die Entzündung des Magens Von Dr. med. Norbert Henning Privatdozent an der Universität Leipzig Paper Price 23.40 marks Pp 235 with 136 illustrations Leipzig Johann Ambrosius Barth 1934

In the past ten years a reawakening of interest in chronic gastritis has occurred. Konjetzny has correlated the anatomic changes in chronic gastritis to the etiology of peptic ulcer and H. H. Berg has presented the roentgenologic manifestations. Now Norbert Henning has carefully worked out the endoscopic observations by a new instrument, a flexible gastroscope perfected by S. Wolf. The flexibility of this instrument makes it possible to view the greater portion of the mucosa of the stomach. It is pointed out that this method possesses a great

advantage over gastrophotography, as the latter method missed a great portion of the gastric mucosa. The types of chronic gastritis are described and illustrated: the hypertrophic type with changes in the mucosa and with changes in only the submucosa, the erosive type, and the atrophic. In addition, a splendid correlation is brought out with other types of investigation of gastric function, i. e., absorption from the stomach with potassium iodide, stretching the stomach by inflation, examination of stomach flora, examination of stomach contents by histamine stimulation and the neutral red test, and examination of dried gastric juice. The differential diagnosis, prognosis and therapy of chronic gastritis are well presented. Most important, and entering on a field in which many opinions have differed, Norbert Henning quite definitely points out the clear path from chronic gastritis to peptic ulcer and gastric carcinoma. In particular this seems to be the answer to the much discussed question of ulcer carcinoma of the stomach. A chapter in which biliary tract disease is also attributed to chronic gastritis, however, does not stand on such a firm basis. The book ends with a discussion of achylia gastrica differentiated by the newer methods of the last few years. This book should be read by every one who is interested in gastroenterology. It restricts the claims of the sempsiychiatrists in medicine who have ascribed peptic ulcer to vagus changes, pituitary gland changes and body types, and it serves to bind the subject once more to physiopathology, where it belongs.

Medicine in Virginia in the Nineteenth Century. By Wyndham B. Blanton, M.D. Cloth. Price \$7.50. Pp. 466, with illustrations. Richmond: Garrett & Massie, Inc. 1933.

This volume completes the series on the history of medicine in Virginia, prepared under the direction of the Medical Society of Virginia. The two previous volumes covered the period from 1607 to 1700 and from 1700 to 1800, respectively. This volume, which covers the period from 1800 to 1900, is written and published in the same interesting and attractive style that characterized the other volumes.

The opening chapters concern the early efforts to organize medical schools. There were no medical schools in Virginia during the first quarter of the nineteenth century. Most of the Virginia students found their way to the University of Pennsylvania, from which up to 1816 there had been 4,254 students graduated in medicine from the South, and of these 1,749 were from Virginia. Likewise, many Virginians graduated from Jefferson Medical College during that period. The medical department of the University of Virginia was planned by Thomas Jefferson, who had in mind a broad cultural education of Virginia youths more than the turning out of physicians. This idea was evident as late as 1889, when the visitors went on record as favoring the subordination of clinical to theoretical instruction. So much emphasis was placed on this idea that later it became difficult to introduce the practical clinical type of instruction. The University of Virginia was further distinguished among American universities about 1840 when the policy was announced that neither the length of time nor the number of courses taken would have any bearing on the graduate's qualifications for the M.D. degree, but that a comprehensive examination would be the sole criterion for his fitness for this honor. In the last decade of the nineteenth century, clinical teaching rapidly assumed the prominence it had been denied. In 1888 the Cottage Hospital and Dispensary in Charlottesville were opened, where bedside instruction was given to students, in 1901 the nucleus of the present university hospital was opened. Seventeen physicians of Richmond and Manchester met, Dec. 15, 1820, and formed themselves into what was "to be styled the Medical Society of Virginia." About 1846 an attempt was made at state-wide organization, and the society was incorporated by an act approved Jan. 14, 1871. The American Medical Association held its fifth annual session in Richmond in May 1852 and again met in Richmond in May 1881. Virginia contributed numerous leaders in the Association's activities. Beverley R. Wellford of Fredericksburg was elected President in 1852 and Hunter McGuire in 1892. Other presidents of the American Medical Association who were born in Virginia and the dates of their election to office were Nathaniel Chapman, 1847, A. Y. P. Garnett 1888, W. W. Dawson, 1889, and R. Beverly Cole, 1896.

The first medical periodical to appear in Virginia was the *Stethoscope and Virginia Medical Gazette: A Monthly Journal of Medicine of the Collateral Sciences*, first published in 1851 and edited by Dr. Philip Gooch, who was prominent in the early work of the American Medical Association, having served as secretary of the meetings at Charleston and Richmond. He died of yellow fever in 1855. This publication was purchased from Dr. Gooch by a committee for the Medical Society of Virginia and converted into the organ of the society. It was sold at public auction in 1855 by the state society to its former publishers, however, and within a few months was amalgamated with the *Virginia Medical and Surgical Journal*. The new magazine appeared first in January 1856, with the title of the *Virginia Medical Journal*.

The history of hospitals in Virginia is taken up next. There are thirty-three hospitals operating in Virginia today which were founded before the year 1900. There is an interesting account of various epidemics that occurred during this period. Yellow fever visited Norfolk in 1800, occasioned by the arrival of three infected ships from the West Indies; other epidemics occurred in 1802, 1803, 1805, 1821, 1826 and 1852. The most memorable epidemic occurred in 1855, when there were about 2,000 deaths in Norfolk from yellow fever. Asiatic cholera made its appearance in Virginia in July 1832 and again in 1840 and 1850.

The remainder of the volume is concerned chiefly with the contributions to medicine made by Virginians and with their services in the military and public health services of the United States. The Medical Society of Virginia may well be proud of its three volumes of medical history.

Über die Darstellung des zentralen und peripheren Nervensystems im Röntgenbild. Von Prof. Dr. Walter Jacobl, Direktor der Nervenkl. im Stadt Krankenhaus Magdeburg-Südendurg. Prof. Dr. Wilhelm Lebr, Direktor der chir. Klinik des Stadt Krankenhauses Magdeburg-Alstadt und Priv. Doz. Dr. Otto Wüstmann, Chefarzt der chirurgischen Abteilung des St. Katharina Krankenhauses Königsberg. I. Pr. VII. einem pathologischen anatomischen Beitrag von Dr. Julius Hallervorden, Oberarzt an der Landesirrenanstalt Landsberg. W. Paper. Price 9.40 marks. Pp. 41 with 31 illustrations. Leipzig: Johann Ambrosius Barth, 1934.

This brief monograph records the attempt of the authors to demonstrate various structures within the body by means of a radioactive substance called Thorotrast (a 25 per cent colloidal suspension of thorium dioxide). This substance seems to be well tolerated by the tissues of the body and is concentrated in the reticulo-endothelial system. When injected into the cisterna magna of animals it causes generalized tetanic cramps. The authors have made cautious attempts to use it in the subarachnoid cavity of human beings but the results, although interesting, are not satisfactory. The authors conclude that they are not yet ready to advise its use in the diagnosis of lesions of the nervous system. It may be of use as a medium for anatomic investigation, since it is absorbed from the subarachnoid space along the tissue spaces surrounding the spinal nerves, a study of which may throw light on the spread of certain infections to the central nervous system.

The Renaissance of Medicine in Italy. By Arturo Castiglioni, M.D. Professor of the History of Medicine at the University of Padua. The Hideo Noguchi Lectures. Publications of the Institute of the History of Medicine, the Johns Hopkins University. Third Series. Volume I. Cloth. Price \$1.50. Pp. 91. Baltimore: Johns Hopkins Press, 1934.

From the University of Padua and an environment that, the author says, must force one to be interested in the history of medicine, Castiglioni came to America to deliver these three charming lectures. The word charming is used advisedly. While these lectures are serious, philosophic and richly informing, they are written in the easy flowing style of the essay, with an occasional light touch of humor and with the attractive imagery of one who is poetically minded without being unduly sentimental as is occasionally true of modern Italian writers. If his imagery is at times so involved as somewhat to obscure the thought it is pardonable because of the author's enthusiasm and sincerity. His aim is to trace the sequence of ideas rather than of facts. He regards the rebirth of medicine as but a part of the general revival of learning. He shows how it was intimately linked to other branches of science to art, to literature and to culture in general. Furthermore he points out the relation of these new ideas to modern medicine. He finds in this period of Italy's medical history the beginnings of

research and experiment, the birth of the real study of anatomy, physiology and clinical medicine. He wisely confines his more detailed discussion to the work of a few men. The leader in the rebellion against astrology and dogmatic medicine was Leonardo da Vinci the "truly universal man," the "first truly great scientist of the Renaissance." He dwells on the influence of Vesalius on the study of anatomy, and of Cesalpino in advancing knowledge of the circulation of the blood. He regards Fracastoro as the father of modern pathology, whose writings reveal many views that are almost modern not only as to the contagiousness of syphilis but as to infection and immunity in general. If Castiglioni seems to be too strongly pro Italian in presenting the claims of Italian medicine, it must be remembered that his topic is the renaissance of medicine in Italy. He is really broadminded. One interested in this topic will find these essays stimulating and refreshing.

Clinical Investigation of Cardiovascular Function. By V. Pachon. Professor of Physiology in the Faculty of Medicine of Paris and R. Fabre, Professor of Physiology, Director and Examiner in the Faculty of Medicine of Bordeaux. Translated by J. F. Halls Dally, M.A., M.D., M.R.C.P., Senior Physician to the Mount Vernon Hospital, Montreal. Cloth. Price 1.0s. Pp. 232 with 87 illustrations. London: Kegan Paul, Trench, Trubner & Company Ltd. 1934.

This volume is an attempt to present some of the instrumental methods of evaluating the functions of the heart. The aim of the authors apparently was to apply the physiologic approach to the analysis of cardiovascular disorders. A great deal of emphasis is laid on the cardiogram for registering the apex beat, a method little utilized by American cardiologists. The records used in this section and in that dealing with the jugular pulse are relatively crude. The sections on electrocardiography and roentgen examination are simple and succinct. A large section of the book is given to the development of sphygmomanometry in which the use of the oscillogram, which Pachon himself designed, is developed at great length. The determination of systolic, diastolic and mean pressures is described and the evidence for using these points evaluated. The many possible uses for which the oscillogram can be employed are developed in detail, so that one gets the impression that the authors are laboring the merits of this instrument. This method has had great vogue among French physicians and the exposition offers a quick view of its present status among French cardiologists. The presentation of the sections dealing with the capillary circulation with venous pressure and with the viscosity of the blood, are simple and clear. A number of so-called functional tests of the circulation are included but on the whole are not especially useful. The translation could have been improved in that more appropriate words might have been substituted for the literal translation of some of the French technical terms. The volume will be interesting to the internist desiring to acquaint himself with the point of view of a large part of the French school of cardiologists.

The Physician's Art: An Attempt to Expand John Locke's Fragment De Arte Medica. By Alexander George Gibson. Cloth. Price \$3. Pp. 237. New York & London: Oxford University Press, 1933.

On page 49 is the following paragraph: "Practice is based upon the principles both of the science and of the art of medicine. The principles of the art, however, must be supplemented by rules governing certain procedures for those circumstances in which many of the factors are not clear, with their aid are formed the empirical lines of conduct. But there are principles of conduct for the doctor in each of his tasks and duties towards his patient and to the patient's friends, towards the community and his colleagues, that are based on facts quite other than those of the science of medicine." The book is concerned with a discussion of principles and precepts that should guide the physician in his practice. The subject is handled in short, pithy paragraphs and covers such features as diagnosis, prognosis, treatment, the ethics and management of practice, the physician himself, and optimism. In addition there is a discriminating chapter on art and science. The introductory pages are concerned with John Locke's fragment *de arte medica* which furnished the inspiration for the writing of this volume. The scope of the work may be learned from noting the headings of a few paragraphs selected at random: art is individual, trivial signs not to be dismissed as neurotic, rela-

tive value of signs, competence in the use of drugs, the one-remedy physician, what to tell the patient, on the time to summon relatives, consultants, of fees, humanity, manners, probity. The physician who has often been perplexed by problems of practice will find many helpful hints in these pages, which are written—and well written—by one whose knowledge and wisdom have clearly been gained by a rich experience at the bedside of the patient.

Demonstrations of Physical Signs in Clinical Surgery. By Hamilton Bailey, F.R.C.S., Surgeon Royal Northern Hospital, London. Fourth edition. Cloth. Price \$6.50. Pp. 287 with 335 illustrations. Baltimore: William Wood & Company, 1933.

The fact that only six years have elapsed since the publication of the first edition proves the popularity of this comprehensive work. As the title implies, the volume describes physical signs of importance in clinical surgery. The book consists of twenty-five chapters, each devoted to the discussion of characteristic clinical signs and their elucidation according to the topographic location of the lesion. For instance, one chapter is on the thorax, another on the shoulder, arm and forearm, a third on nonacute abdominal conditions. The reader is impressed with the simplicity and clarity of the text, which is interspersed with numerous exceptionally beautiful reproductions of photographs or schematic drawings. The book is highly recommended as a reliable source of information on this important subject not only to students but also to general practitioners.

L'évolution de la lutte contre la syphilis. Un bilan de 25 ans. Nancy 1907-1932. Par Louis Spillmann, doyen de la Faculté de médecine de Nancy. Paper. Price 30 francs. Pp. 292 with illustrations. Paris: Masson & Cie, 1933.

This volume reviews what has been done at Nancy from 1907 in controlling venereal diseases, especially syphilis. As the author well states in the introduction, "the struggle must be centered around an epidemiologic base." For every new case of syphilis, the source must be found and cared for. The author reviews the situation before the World War, the changes that took place during the war in a department so close to the front as Nancy and finally the vigorous endeavors that have been carried out since the war in the antivenereal campaign. Spillmann considers clandestine prostitution rather than regulated, medically controlled prostitution to be the great spreader of syphilis. He thinks the "conspiracy of silence in regard to venereal diseases should cease." The public, instead of receiving its education in the back alleys, should get it in the form of lectures, through the press and through the use of placards, theaters and the radio. Emphasis should be placed on the early diagnosis and on thorough treatment of syphilis. Moreover, syphilis poorly treated means later great expense to the state. It means the death of many children born of syphilitic parents. Spillmann is a firm believer in careful compulsory examination of all candidates for marriage. He considers social service a necessary adjunct to any real attempt to carry on a campaign against syphilis. As is usual in most French books, the index is simply replaced by a table of contents. The book is embellished with reproductions of photographs and plates illustrating what Spillmann has succeeded in doing at Nancy in his fight against venereal disease. To the person not necessarily a physician, interested in this type of campaign, the book is interesting and helpful and is to be recommended.

Neuroanatomy: A Guide for the Study of the Form and Internal Structure of the Brain and Spinal Cord. By J. H. Globus, B.S., M.D., Associate Professor of Neuropathology and Neuroanatomy, New York University and Bellevue Hospital Medical College. Sixth edition. Fabricoid. Price \$3.50. Pp. 240 with 89 illustrations. Baltimore: William Wood & Company, 1934.

This is a laboratory guide intended to give the student specific directions for the dissection of the brain and the microscopic study of the brain and spinal cord. A chief feature is a series of fifty-three outline drawings, which the student is expected to fill in and label. When used in conjunction with textbooks and atlases giving fuller descriptions and more adequate illustrations, this laboratory guide should be helpful in those courses which follow the general plan of presentation here adopted.

Dissecting Aneurysms By T Shennan Medical Research Council Special Report Series No 193 Paper Price 2s 6d 1p 138 with 30 illustrations London His Majesty's Stationery Office 1934

This is an analysis of 300 cases of dissecting aneurysm of the aorta, including three of the pulmonary artery. A brief and interesting historical introduction is given. There are seventeen cases from the author's own experience, with complete reports and drawings of nearly all the specimens. These are summarized separately. A detailed analysis is made of the entire 300 cases, including the author's. The etiology and symptomatology are described in detail. A feature common to all is degeneration of the middle coat of the vessel, which usually gives way before the inner coat. The cause of the tear is not definitely agreed on, but it is probably the cumulative effect of toxins throughout life. Syphilis is not apparently a factor. This differentiates the ordinary variety from the dissecting type. The dissecting aneurysm usually originates in the ascending aorta, and dissection is often extensive. Death nearly always results from hemorrhage into the pericardial sac. The condition is not always fatal. About one third have died suddenly, one third within a few hours or days and one third after several days, weeks or, rarely, longer. Clinically the symptoms begin with a sudden onset in one having no previous symptoms of cardiovascular disease. Occasionally they have occurred in the second decade, although they were most common in middle life. They have been diagnosed rarely during life. The book has been made authoritative, owing to the experience of the author and his detailed descriptions.

Circumcision in Man and Woman Its History Psychology and Ethnology By Felix Bryk Translated by David Berger M.A. Cloth Price \$6 Pp 342 with 55 illustrations New York American Ethnological Press 1934

This volume, first published in 1930 purports to be a scientific, ethnologic and medical survey of the ancient rite of circumcision. It describes the methods and rituals of various races. One chapter, on "Function of the Prepuce in Coitus," is concerned more with the psychologic than with the physical phases of the problem. The book is illustrated and has a bibliography. The price considering the scope of the volume, seems to be beyond all reason.

Clinical Contraception By Gladys M Cox M.B. B.S. Medical Officer to the Society for the Provision of Birth Control Clinics. Introduction by Lord Horder of Ashford, K.C.V.O. M.D. F.R.C.P. Cloth Price 7s 6d Pp 173 with illustrations London William Heinemann Ltd 1933

This is a British contribution to one of the most rapidly developing literatures in the medical field. The author prefaces her volume with the statement that she is not commercially interested in any of the proprietary devices discussed in her book. She supports the recommendation of the occlusive pessary together with antiseptic pastes and douches as the ideal method.

Nursery Guide A Vade Mecum on Infant and Child Care By Louis W Sauer Ph.D. M.D. Associate in Pediatrics Northwestern University Medical School Chicago Ill Third edition Cloth Price \$2 Pp 208 with 18 illustrations St Louis C.V. Mosby Company 1933

This seems to be one of the better of the numerous books on infant care written for the mother. The material is presented in simple language, neatly arranged and yet scientific in every detail. In addition to feeding and general care there is much valuable material for the mother concerning the common ailments of childhood, care during sickness and the symptoms of the contagious diseases. The book would be improved by the addition of more illustrations.

La digitale Par F. Henricjean professeur à l'Université de Liège et R. Waucourt chef des travaux au laboratoire de thérapeutique de l'Université de Liège Paper Price 15 francs Pp 192 with 15 illustrations Paris Masson & Cie 1930

The authors of this monograph have apparently had much personal experience with the actions of digitalis, both in the laboratory and in the clinic although their work is but little known in America. The discussion is arranged in logical sequence. There are preliminary considerations of the anatomy and physiology of the heart. The glucosides of digitalis are briefly described. The methods of biologic standardization are given and there follow chapters on pharmacology, toxicology and therapeutic action. No new facts are presented. The

bibliography, though making no attempt at completeness, is inadequate because of the omission of key papers. The volume is not sufficiently comprehensive to serve as a work of reference or critical enough to be of value as a summary of current knowledge concerning digitalis.

The Great Physician A Short Life of Sir William Osler By Edith Gillings Reid Popular edition Cloth Price \$1.50 Pp 299, with portrait New York & London Oxford University Press 1934

This volume, first published in August 1931, passed through five printings and is now issued in a popular priced edition. Its wide distribution testifies to its merits as a sympathetic, easily readable and inspiring work.

Housing Conditions and Respiratory Disease Morbidity in a Poor Class Quarter and in a Rehousing Area in Glasgow By C. M. Smith Medical Research Council Special Report Series No 192 Paper Price 9d 1p 36 with 2 illustrations London His Majesty's Stationery Office 1931

This is a study of the morbidity for one year occurring among a population of approximately 2,000 persons in a poor district in Glasgow. Half the population under observation was housed in a representative slum area, half in a "rehousing scheme" area. The collected results show a greater morbidity in the rehousing area than in the slum quarter. Racial differences are thought to have influenced the results, and the general outcome of the inquiry is considered by its sponsors to illustrate the difficulty of reaching reliable conclusions about the relation of housing to health. During the period of observation an epidemic of influenza visited Glasgow, and interesting data are given respecting its incidence, character and influence on the general trend of respiratory diseases.

Medicolegal

Abortion, Accidental Cause of Determinable by Medical Testimony, Chiropractor as Expert Witness—The plaintiff suffered a miscarriage, which she attributed to the negligence of the defendant oil company in shutting off the gas, during extremely cold weather, by which her house was heated. As a result of this exposure, the plaintiff contended, she suffered a nervous shock, contracted a cold, became ill therefrom, and a miscarriage resulted. The jury returned a verdict for the plaintiff and the defendants appealed to the Supreme Court of Oklahoma, contending, among other things, that the plaintiff had failed to prove that her miscarriage was due to any negligent act of the defendants, that whether the plaintiff's injury was the result of the defendants' acts was a matter to be established by expert testimony and that there was no such testimony in the case. With this contention, the Supreme Court agreed. The general rule is, said the court, that where injuries are of such a character as to require skilled and professional men to determine the cause and extent thereof, the question is one of science, and must necessarily be determined by the testimony of skilled professional persons. It cannot be determined from the testimony of unskilled witnesses having no scientific knowledge of such injury. The plaintiff, continued the court, was incompetent to testify that the exposure resulting from the alleged negligent acts of the defendants caused the miscarriage. A chiropractor, called by her as an expert witness, testified as to the causes that might produce a miscarriage, but when this witness was asked the direct question as to what, in his opinion, did cause the plaintiff's miscarriage, he answered that he did not know. A jury should never be permitted to speculate on or infer what an expert witness refuses to express an opinion about.

The defendants further contended that "a chiropractor is not competent to testify concerning questions requiring knowledge of medical science." By the use of the term "medical science" said the court, the defendants unduly limited the proposition. There are many methods of treating and healing the human body, which might not be termed "medical science" yet their qualified practitioners are eligible to testify as expert witnesses within the scope of their knowledge, according to their qualifications. The practice of chiropractic, said the court as a method of treating and healing is permitted and regulated in Oklahoma by statute. The course of study and preparation

precedent to admission to practice is prescribed by law. When a duly licensed chiropractor establishes his qualifications to testify as a chiropractor, he is competent to testify as an expert witness. The question of whether his qualifications have been established and the extent to which his competence goes is a question for the trial court, in the same manner and to the same extent as any other expert witness. The weight and value of his testimony is a matter for the jury and is subject to be supported or minimized by examination and cross-examination, just as is that of any other expert witness. The judgment of the trial court was reversed and the cause remanded for further trial.—*Inter Ocean Oil Co v Marshall (Okla.)*, 26 P (2d) 390

Malpractice Workmen's Compensation Award a Bar to Malpractice Action—The plaintiff-employee suffered an injury in the course of his employment and was attended by the defendant a physician supplied by the employer. Later the employee was awarded compensation under the workmen's compensation act. He then instituted the present action against the defendant-physician, alleging negligence in the treatment of his injury. The trial court agreed with the physician's contention that the award under the workmen's compensation act operated as a bar to the present action and entered judgment in his favor. The employee thereupon appealed to the Supreme Court of Iowa.

At common law, said the Supreme Court, if a physician, called to treat an injured person is negligent or unskilful, the original wrongdoer is liable for both the original injury and for any aggravation thereof due to the physician's malpractice. It follows that where the injured person has recovered damages from the wrongdoer, he is deemed to have received full satisfaction for the injury suffered and for any aggravation due to unskilful medical treatment. He cannot thereafter bring another suit against the physician to recover damages for an aggravation of the original injury. *Phillips v Wernsdorff*, 243 N W 525

The employee, however, contended that the workmen's compensation act of Iowa authorizes him to maintain this action. In support of that contention, he cited section 1382, Iowa Code, reading as follows:

When an employee receives an injury for which compensation is payable under this chapter and which injury is caused under circumstances creating a legal liability against some person other than the employer to pay damages the employee or his dependent or the trustee of such dependent may take proceedings against his employer for compensation and the employee or in case of death his legal representative may also maintain an action against such third party for damages.

But answered the Supreme Court, the section cited permits an action against an original wrongdoer one who is liable for all the injury suffered by the employee. The injury referred to in this section is the original or substantive injury which caused the disability of the employee. Here the employee is not suing an original wrongdoer; he is suing the physician not for the original injury but for its later aggravation. He may not under the act split his cause of action and take the benefits of the workmen's compensation act as to the original injury and then proceed against the physician for his want of skill or for his negligence. The court held that the award under the workmen's compensation act worked a satisfaction of any claim against the defendant physician. The judgment of the lower court in favor of the physician was accordingly affirmed.—*Ponce v Watt (Iowa)* 251 N W 78

Accident Insurance "Disease" Defined—The appellant insurance company issued to the insured two policies providing certain benefits if he should die by external violent and accidental means. No benefits were payable if death resulted directly or indirectly from disease. Apparently, the insured's car and the insured's dead body were found in a stream. The beneficiaries brought suit on the policies alleging that the insured had been drowned. The insurer contended that the death was due to heart disease. From a judgment for the beneficiaries the insurance company appealed to the Supreme Court of Arkansas.

The insurance company argued that the trial court had erred in permitting two embalmers, who had prepared the insured's

body for burial, to testify that the death was due to drowning. These witnesses testified that they had had a number of years of experience in handling dead bodies and among the bodies so handled were deaths caused by drowning. They were competent, said the Supreme Court, to express an opinion on the subject. A nonexpert witness may testify as to his opinion after stating the facts on which the opinion is based. Their testimony was also competent because "a witness' opinion is admissible as evidence, not only where scientific knowledge is required to comprehend the matter testified about, but also where experience and observation in the special calling of the witness gives him knowledge of the subject in question beyond that of persons of common intelligence." *Little Rock and M Railway Co v Shoecraft* 56 Ark 465, 20 S W 272

The insurance company complained of the following instruction given by the trial court:

Even though you should find that some disease or bodily weakness contributed to Mr. McCombs' death by disabling him from controlling his automobile and causing it to go into the water or otherwise still if you also believe from the testimony that such disease or bodily weakness was not a settled condition to which he was subject but a temporary disturbance or enfeeblement then the court instructs you that it would not prevent a recovery by plaintiffs and if you believe from the testimony that the deceased was alive when he went into the water and his death there resulted from accidental drowning then your verdict should be for the plaintiffs notwithstanding you should find that such disease caused him to go into the water or otherwise contributed to his death.

The theory on which this instruction submitted the case to the jury, viz., that a disease which would exempt the insurance company from liability under the policies would need to be a settled condition as distinguished from a temporary disorder, was proper, said the Supreme Court. Insurance policies will be construed most favorably to the insured since the policy is couched in language chosen by the insurer. The policies used the general term "disease" to create an exception to the general coverage. The meaning of the word "disease" could have been restricted by the insurance company had it so desired, and, since there were no restrictions in reference thereto, it should be given its usual and ordinary meaning. To ascertain that meaning the court referred to Webster's International Dictionary, which defines the word as follows: "A disease is usually deep seated and permanent or at least prolonged, a disorder is often slight, partial and temporary." Consequently, the court held the instruction complained of correctly stated the law of the case.

The judgment in favor of the beneficiaries was affirmed.—*Pacific Mutual Life Insurance Co v McCombs (Ark.)* 64 S W (2d) 333

Traumatic Keratitis Attributed to Malpractice—A physician removed a chalazion from one of plaintiff's eyelids. After the operation, he dropped some liquid into the eye. A severe burning pain followed. The physician wiped out the eye, put something into it, and gave the plaintiff some medicine to take with him for use in the eve. He treated the plaintiff daily for four days but the eye continued to be inflamed and the pain persisted so the plaintiff went to a hospital. There a "large ulcerative area involving almost entire cornea" was found and a diagnosis of "ulcerative keratitis" was made. The plaintiff practically lost the sight of his eye. He sued the physician, charging negligence in putting into the eye the liquid that caused the burning pain. During the trial the physician died and his administrator defended. The trial judge directed a verdict in favor of the administrator and the plaintiff appealed to the Supreme Judicial Court of Massachusetts.

The burden said the Supreme Judicial Court was on the plaintiff, to establish a causal connection between his injury and the negligence of his physician. Negligence of a physician imports a failure on his part to have and to use the skill and care which members of his profession commonly possess and exercise under corresponding circumstances. The plaintiff, however introduced no testimony as to the care and skill generally possessed and commonly used or as to the methods generally employed, by physicians undertaking such an operation as was performed in this case. The record contains nothing on which to base a finding that the physician who

was charged with negligence did not possess adequate skill to undertake and perform the operation or that the growth was not removed with requisite skill and care

Statements made by the physician, said the court, did not warrant an inference of negligence. Before beginning the operation the physician assured the patient that he could perform it without the aid of an assistant, but there is nothing in the record to indicate that such an operation required the presence of an assistant or that the absence of an assistant played any part in what happened. Apparently, the physician, after applying the drops to the patient's eye, asked him if "caustic" had been put into his eye when similar operations were performed on him before, but that would not warrant the inference that the doctor had used a "caustic" or that the use of a caustic was improper or negligent. Two days after the operation the patient charged his physician with having ruined his eye, his life, and his business, and the physician replied, "Don't you worry. Let me worry", but such a reply to such an outburst from a suffering patient affords no basis for finding that the physician thereby admitted that his negligence was the cause of his patient's condition. In all this concluded the court, there could be found no admission of negligence.

A jury may draw an inference of negligence only from acts tending to show negligence, admitted by the defendant or established by the evidence including expert testimony, or from common knowledge and experience. Here there was no expert evidence other than what appeared in the hospital chart. The mere fact that pain, inflammation, and an ulcer of the eye followed the operation would not justify the inference of want of proper skill and care on the part of the physician or warrant the conclusion that the conditions complained of were the result of the physician's negligence. No evidence was introduced to show the nature of the liquid put into the eye, the purposes for which such liquid is commonly used, and its ordinary effects and characteristics, or to show whether it was or was not in general use by physicians after or in connection with such operations. The fact that an unidentified liquid placed in an organ as sensitive as an eye was followed by pain and inflammation would not of itself warrant the inference that its use was improper. There was no evidence as to the character or extent of injury which might cause an ulcer in the eye as to the ordinary origin, characteristics and development of such ulcers or as to causes which are commonly adequate to produce them. The record, in the opinion of the court, lacked elements necessary to a reasonable inference that the physician's negligence caused the conditions appearing in the eye after the operation. The common experience and knowledge of a jury of laymen could not supply the lack of such testimony, and the doctrine of *res ipsa loquitur* is not applicable where, as here, the common knowledge or experience of men is not extensive enough to permit it to be said that the plaintiff's condition would not have existed except for the negligence of the person charged.

The judgment in favor of the physician's administrator was affirmed—*Semerjian v Stetson (Mass)*, 187 N E 829

Workmen's Compensation Acts Streptococcus Meningitis Following Fall—In the course of his employment, on January 26, Williams fell down an icy stairway, striking his back and neck. He had severe pains in the injured parts was unable to sleep, and complained constantly. He had vomiting spells, and a discharge from his ear. On February 2 he became unconscious and two days later he died. An autopsy on the head showed no indication of external injury, and a diagnosis of streptococcus meningitis was made. At a hearing before the industrial accident board, on an action instituted by his widow under the workmen's compensation act of Montana, the physicians who attended the deceased gave it as their opinion that the fall had something to do with the fatal infection. The board awarded compensation, its award was affirmed by the district court, Silver Bow County, and the employer and its insurance company appealed to the Supreme Court of Montana.

The fact of the fall and of the immediate and continuing disability, said the Supreme Court, was not denied. That meningitis occurred and was the immediate cause of death was admitted. The only break in the sequence of clearly estab-

lished facts was the gap between the injury and the disease. Because the physicians did not testify positively that the disease was a direct result of the injury, the appellants contended that that matter was left open to conjecture and surmise on the part of the board. But the physicians testified, said the court, that in their opinion the injury had something to do with the disease and therefore, of course, with the death. Although there was no direct testimony that the disease was the result of the injury, the board had a right to consider not only the direct evidence but also all the circumstances of the case. In the opinion of the court the facts and pertinent circumstances in the record were sufficient to support the finding of the board, and the court accordingly affirmed the award of compensation made to the widow—*Williams v Brownfield Carty Carpet Co (Mont)*, 26 P (2d) 980

Medical Practice Acts Acquittal of Physician on Criminal Charge No Bar to Revocation Proceedings—The trial and acquittal of a physician, says the district court of appeal, second district, division 1, California, in a criminal action charging murder by abortion is no bar to a subsequent proceeding under the medical practice act to revoke his license to practice for producing or aiding or abetting a criminal abortion. Proceedings before the board of medical examiners looking toward the revocation of a license are not criminal in character. They are designed, rather, to protect the public by eliminating from the ranks of medical practitioners those who are found by members of their own profession to be dishonest, immoral or disreputable—*Bold v Board of Medical Examiners (Calif)*, 26 P (2d) 707. *Tiavler v Board of Medical Examiners (Calif)*, 26 P (2d) 710

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Recognition of Allergic State by Tissue Examination—Steinberg states that there is a distinct histopathologic picture of the mucosa of the entire respiratory tract and of the accessory nasal sinuses associated with the allergic (atopic) state. The morbid changes are of a similar nature in the atopic conditions of asthma, hay fever and rhinitis (hyper-trophic and marked secretory activity of the mucous glands, presence of a large amount of mucus in lumens eosinophils—from 15 to 90 per cent of all cells, edema of tissue thickening and hyalinization of the basement membrane and hyperplasia of the goblet cells with hypersecretory activity). In asthma, in addition to the lungs the rest of the respiratory tract including the nose and almost invariably the accessory sinuses show these morbid changes. This constant pathologic picture of the respiratory nasal and sinus mucosa permits recognition of the allergic (atopic) state involving these organs.

Differentiation of Streptococcus Toxins by the Skin Test—King and Conlin observed the results of skin tests involving the use of samples of toxins and antitoxins derived from the scarlet fever and erysipelas hemolytic streptococci and hemolytic streptococci isolated from severe cases of puerperal sepsis. The results not only confirm the conclusions which were reached by the Dicks that the soluble toxins

produced by scarlet fever and erysipelas streptococci are immunologically specific and distinct" but also suggest that the toxin produced by certain hemolytic streptococci isolated from cases of puerperal septicemia is specific and distinct.

Diuresis Produced by Injection of Dextrose—Woodward induced diuresis in two normal infants by the intravenous injection of a 20 per cent solution of dextrose. She studied the urinary and fecal excretion of nitrogen, chlorides, phosphates, sodium and potassium during the period of active diuresis and for nine succeeding days. There was a rapid loss of sodium and of chlorides in the urine during diuresis, but these losses were made up rapidly in the succeeding periods by the retention of sodium and of chlorides within the body, as indicated by the marked decrease in urinary output. Fluctuations in the urinary excretion of the remaining ions during the entire period studied were insignificant. Fecal excretion of these elements, and of calcium, showed no unusual change either during or after diuresis. In these observations the use of a hypertonic solution of dextrose as a diuretic did not cause any prolonged depletion in the body of any of the elements studied.

The Schick and the Dick Tests in New-Born Infants—Rothholz and Kuttner found the Schick and Dick tests unreliable in new-born infants. No adequate explanation has been found for the discrepancies observed between the reactions of adults and new-born infants with either of these tests. It seems possible that the failure of new-born infants to react to both the Schick and the Dick test in the absence of antitoxin may be related to a nonspecific property of the skin of the new-born, which is known to be refractory to substances of primary toxicity, such as eel serum and chemical irritants.

Effect of Epinephrine on Lipemia of Diabetic Patients

—Sullivan and Cameron selected eleven diabetic patients, all of whom were aglycosuric or nearly so, and clinically well. After a fast of fifteen hours a specimen of blood was obtained from each patient and 100 Gm of cottonseed oil was administered orally. Blood samples were taken three, six and nine hours later. Total lipoids were determined by the method of Ruckert. With the exception of two cases, which continued to show a rise even at the ninth hour, the peak of absorption was reached at the sixth hour, and by the ninth hour the lipid values were approaching the fasting values. Ten days later these eleven patients were again given 100 Gm of oil after fasting fifteen hours. Blood specimens were taken just before the oil was drunk and three, six and nine hours after. At two and one-half, five and one-half and eight and one-half hours after the ingestion of the oil, 1 mg (1 cc) of epinephrine was given subcutaneously (total dosage, 3 mg in six hours). The effect of the epinephrine on the absorption curves was striking. In all except one, who was the only patient in the group taking a high fat diet, the epinephrine caused a decided lowering of the blood lipoids as compared with the values for the lipoids when no epinephrine was given. The exception was a young woman who had lost much weight, with suspected pulmonary tuberculosis, who in the epinephrine experiment became nauseated, developed tachycardia, experienced substernal pain and vertigo and was greatly distressed. Thus she should perhaps be excluded from this group, which consisted of healthy subjects on low fat diets. Although all the other patients experienced the physiologic effects of the epinephrine and commented on a "strange feeling, nervousness, dizziness and heart consciousness," this was the only patient who was distressed.

Conservative Treatment of Peripheral Vascular Disease—Starr gives the results of applying heat, desiccation and oxygen in the treatment of thirty-five consecutive patients with advanced peripheral vascular disease. In all, there was a question whether amputation was not inevitable. The marked degree of impairment of circulation is further indicated by the fact that in only two cases did the histamine puncture test on the dorsum of the foot cause a wheal or flare. In most cases the diseased foot was first placed in an ordinary foot cradle containing an electric bulb. After twenty-four to forty-eight hours, the thermoregulated cradle was substituted. If pain was not relieved within a few days other procedures were tried. These included the vasodilator drugs, acetyl- β -methylcholine or sodium nitrite, oxygen in a few cases and nerve block. Only when conservative measures failed was

amputation performed. All the patients agreed that great comfort was secured from the use of the thermoregulated cradle than from either the unregulated or the unheated type. In two cases of diabetes toes had been amputated, but healing had not occurred under hospital treatment after two and four months, respectively, it did occur slowly after the legs had been placed in a thermoregulated cradle. In two elderly patients, in whom gangrenous areas were removed below the line of demarcation, healing of the stump occurred while the thermoregulated cradle was employed. The application of from 50 to 80 per cent oxygen, together with regulated heat, had been tested in four cases, in all of which advancing gangrene was present and intense pain was felt. In only one was there any suggestion that advance of the gangrene was delayed. There was, however, a change in color in every case, together with definite partial relief of pain. Desiccation was used whenever frank gangrene was present. In fourteen cases, the toes being kept apart, the gangrenous areas became mummified and shriveled to half their original size. Even though blebs formed, the moisture dried up so quickly that sloughing and infection did not follow.

Leukocytic Injections in Treatment of the Neutropenias—Strumia employed injections of leukocytic cream intravenously in ten cases of agranulocytosis and three cases of miscellaneous neutropenias. The results indicate that an increase in the mature granulocytic cells and considerable clinical improvement may be expected in most cases in from one to four days. The author's method for the separation of the leukocytes from the blood is as follows. Not less than 150 cc of blood is withdrawn from the vein of the donor into citrate solution, divided in large tubes and centrifuged at high speed for thirty minutes. The clear supernatant plasma is withdrawn, part of which is kept for the preparation of leukocytic emulsion later. With a pipet and a rubber bulb the buffy layer of leukocytes that has formed on the surface of the packed red cells is transferred to a Babcock cream tube. Enough of the packed red cells are added to this to bring the surface of the fluid to the neck of the tube. This is centrifuged for twenty minutes at high speed. The leukocytes will now rise to the top. There are usually three well defined layers: clear plasma, suspension of leukocytes and platelets, and leukocytes mixed with some red cells. This last layer has been found to be richer in polymorphonuclears, while the topmost layer contains more lymphocytes. This material and the top layer of the packed erythrocytes are drawn off and suspended in plasma so as to make for each hundred cubic centimeters of blood used from 5 to 10 cc of suspension. The material is used intramuscularly. As a rule, the volume of the packed leukocytes is 16 per cent of the amount of blood used, and the suspension contains about two thirds of the leukocytes present in the blood used. It is essential to separate the leukocytes from the blood as early as possible after the withdrawal of the blood from the donor. The leukocytes thus prepared remain well preserved for a period of seven days at least. The citrate solution, as anticoagulant, is prepared by dissolving 20 Gm of sodium citrate in enough sodium chloride solution to make 100 cc. The percentage of the sodium chloride solution is 0.85. This solution contains 200 mg of sodium citrate per cubic centimeter, which is sufficient to prevent the coagulation of 50 cc of blood.

Effect of Hyperpyrexia Induced by Radiation on Leukocyte Count—Bierman made hourly observations of the changes occurring in the leukocyte count of patients suffering from varied diseases in whom hyperpyrexia was induced by means of radio waves of 30 meters length. An initial reduction, about 25 to 30 per cent, in the number of leukocytes regularly occurs, usually during the first or second hour of treatment. This is constantly followed by a leukocytosis whose maximum, amounting to about 80 per cent above the initial figure, occurs at about the sixth to the ninth hour. These variations are due mainly to changes in the total number of neutrophils, of which the staff neutrophils show the greatest increase. These changes, together with the appearance of other immature forms, indicate a stimulation of the bone marrow. At a later stage the monocytes and lymphocytes also increase in number. Repeated stimulation by heat is followed by a reduction in the leukocytic response.

Fungus Infection in an Infant—Dodd and Tompkins cite a case of fungus infection (histoplasmosis of Darling) that presented a generalized parasitic invasion involving the large mononuclear cells of the blood and tissues. While there were numerous specific organic changes, they were apparently due to the great increase in large mononuclear cells called forth by the parasites and the subsequent mechanical action of these cells. The large mononuclears crowded into all areas including the bone marrow, and filled so many capillary and sinusoidal spaces that there must have been considerable interference with the supply of blood to the tissues. Further they were actively phagocytic of erythrocytes and must have ingested and destroyed great numbers of red cells daily, thereby aiding in the production of the anemia. In addition to the interference with the oxygenation of the tissues which was caused by the blocking of the capillaries and by the anemia it is probable that ventilation was further disturbed by the tremendous infiltration of the lungs with the large mononuclear cells and the collapse of great numbers of alveoli. The extreme acidosis and the necrosis of the cells of the various organs especially of the liver, may well be explained by the marked reduction of oxygenation in the tissues. It is not certain how the parasites functioned in the production of the phagocytic cells or whether the latter were produced throughout the body in general, or

from the specific endothelium only. Mitotic figures were found in the septums of the lungs, in the brain and in the connective tissue of the intestinal villi, as well as in the walls of the sinusoids of the spleen, nodes and bone marrow. Since this case occurred in an infant, the authors feel certain that the saprophytic or mold form of the fungus occurs indigenously in Tennessee.

Artificially Induced Ovulation in the Cat—Greulich induced ovulation in nine of twelve domestic cats by stimulating the distal portion of the genital tract with a glass rod. The minimal length of the interval between stimulation and ovulation was found to be no more than twenty-five hours. He shows that ovulation does not invariably follow normal coitus in the cat, even if the female is clearly in heat when the mating occurs. This is interpreted as favoring the idea that the follicular cycle and the estrous cycle do not necessarily coincide in this form. Though the exact mechanism effecting ovulation in the cat remains to be elucidated, the present investigation definitely eliminates all constituents of seminal fluid as necessary causative factors in that process.

Histamine Therapy of Rheumatic Disorders—Kling states that the alteration of the peripheral circulation is the principle underlying the treatment of rheumatic conditions and disturbances of the vasomotor system, by the application of histamine to the affected parts. The effect of this treatment consists in a dilatation of the minute vessels and smaller arterioles and in an increase of the blood flow and permeability of the vessels, which causes a hyperemia and elevation

of the skin temperature for several hours. Some evidence is given of a longer duration of the capillary dilatation after considerable treatment. The author reviews the results in 554 cases collected from the literature. A definite conclusion of the value of this method is at present possible only in myalgia (myositis). Of 361 cases, 301 were either cured or improved, recurrences were noted in twenty-six. Of the author's twenty cases of myalgia, eighteen were cured or improved and two remained unchanged. Immediate relief of pain and tenderness after the first treatment is of favorable prognostic significance in this group. Thorough examination and treatment of all affected muscles and their antagonists are decisive for the success of the treatment. The material is insufficient in the other conditions to justify a definite conclusion. Secondary myalgia, after trauma, strain and due to static unbalance was benefited in a moderate number of cases. Three cases of calcified subacromial bursa were successfully treated by the author.

Treatment of Internal Hemorrhoids—Kilbourne discusses operative removal of hemorrhoids and also injection treatment. A survey of cases treated by fifty-seven proctologists shows that in 36,648 cases treated by operation there were eleven mortalities and that in 26,262 cases treated by injection there were no mortalities that could be attributed to the treatment. Hemorrhage following operation was reported in 0.573 per cent and following injection in 0.279 per cent. Stricture following operation was estimated at about 0.22 per cent, and after injection methods this group of men had practically no strictures at all. Recurrence of the hemorrhoids was much more frequent after the use of injection methods occurring in at least 15 per cent within three years. Results from the use of phenol in olive and almond oil compared favorably with the results following the use of quinine urea hydrochloride. The double chlorhydracetate of quinine and urea proved to be less likely to cause sloughs than quinine and urea hydrochloride. It is probable that proctologists who are obtaining superior results would be more inclined to answer the questionnaire than those who are having poor results. These figures show what can be attained in proctology at its best.

Diagnosis of Phlebitis in Varicose Veins and the Sedimentation Rate—Biegeleisen states that the blood sedimentation rate has been employed to estimate the degree of inflammation present in varicose veins. Other conditions must be eliminated in order to evaluate its significance properly. A positive test indicates the presence of phlebitis only in the absence of any other infection. The test is roughly a quantitative one in that it estimates the degree of inflammation present. A time interval below one hour is indicative of fairly active inflammation. Rates of two hours or more indicate the probable absence of any activity. Inflammatory conditions, especially the arthritides, influenced the sedimentation rate. In other words a rapid sedimentation time in the presence of arthritis is of no value in the diagnosis of phlebitis. A number of noninflammatory complications do not affect the sedimentation time. These include albuminuria, traces of sugar, hemia and simple goiter. The hemoglobin percentages also had little bearing on the rates, since they ranged between 70 and 100 per cent. Every case presenting a definite active phlebitis gave a definite rapid sedimentation time. In those cases in which the warning of a latent phlebitis, as evidenced by a rapid sedimentation time, was disregarded migrating reactions occurred. In cases in which injection therapy had been given prior to the test, the sedimentation time was of more rapid rate than normally. This means that the chemical phlebitis caused by sclerosive injections influenced the sedimentation rate. To secure uniform results, this test should be made before treatment is begun.

Pustular Eruptions of the Palms and Soles—Andrews and his associates observed fifteen patients having recalcitrant pustular eruptions of the palms and soles. Their cases seem to be similar to those described by Barber and his co-workers and termed pustular psoriasis of the extremities. Bacteriologic and mycotic examinations failed to reveal a local causative organism. The patients were unresponsive to all forms of local treatment, including roentgen therapy. In almost every case there were evident foci of infection. The patients whose foci of infection were removed were cured or showed marked improvement. The difference between these cases and simple dyshidrosis is pointed out. None of the patients had typical lesions of psoriasis that could be definitely diagnosed as such. A study of serial sections in six of the cases failed to show several important changes that are usually held essential for the histologic diagnosis of psoriasis. They did reveal, however, a fairly definite pathologic picture, which would suggest that this condition is an entity. None of the patients responded to therapeutic procedures that are generally effective in producing at least temporary improvement of psoriasis. There is a recalcitrant pustular condition of the palms and soles sometimes caused by focal infections, that resembles pustular psoriasis of the extremities but should not be classified as this disease.

Fatal Case of Monilia Infection of Skin—Rockwood and Greenwood report a fatal case of infection of the skin with *Monilia albicans*. There was a high percentage of lymphocytes constantly present in the blood. Save in lymphoma they do not know of any other disease of the skin giving a similar blood picture. Other features were repeated isolation of the organism from all the cutaneous and oral lesions, negative blood cultures, failure of the patient's serum to agglutinate his own organisms and failure of all treatment.

Ketogenic Diet in Treatment of Epilepsy—Notkin treated twenty institutionalized patients having cryptogenic epilepsy with a ketogenic diet for a period of from 108 to 729 days. The average duration of the diet was 341 days. The ages of the patients ranged from 22 to 47 years. Each patient showed some evidence of mental deterioration. The acetone reaction in the urine was positive in 89.5 per cent of the total number of tests for the whole group during the entire period of treatment. With the exception of two cases there was an increase in the number of convulsions during the period of the diet. No relationship could be established between the occurrence of a convulsion or the frequency of convulsions and the acetone content in the urine. There was a loss of weight during the first two weeks of treatment followed by a gradual gain during the rest of the dietary period. In ten cases basal

metabolic readings were made prior to the institution of the diet and at certain intervals during the diet. Eight patients showed a decrease of the basal metabolic rate during the diet, sometimes reaching low values. Patients with mental deterioration may respond to the ketogenic diet in a manner quite different from that of patients showing no mental deterioration.

Test for Thrombosis of Lateral Sinus—Dandy proposes a ventricular hydrodynamic test by which diagnosis of thrombosis of the lateral sinus can be made with the same degree of accuracy as that obtained with the spinal Tobey Ayer test. Unilateral jugular compression (each side is tested separately) will cause the pressure of ventricular fluid to rise (with exceptions) if the lateral sinus is patent, and the level of the fluid will promptly fall when the venous compression is released. If a rise of the ventricular pressure does not follow jugular compression on one side but follows compression on the other, the lateral sinus is probably occluded or absent on the former side. The use of this procedure instead of the spinal test is suggested only when a ventricular puncture is required to diagnose or eliminate the possibility of a tumor or an abscess of the brain by ventriculography. Under such circumstances it merely makes an additional spinal puncture unnecessary.

Surgical Treatment of Ozena—Wachsberger has used a modification of Lautenschlager's method in the surgical treatment of ozena since 1927. Borries' method is similar to his modification. It differs in the approach in that his operation is performed entirely through the nose while Borries uses the oral route. By reducing the volume of the nasal cavity and relatively enlarging its surface a smaller quantity of air passes over a larger surface. As a result oxidation and evaporation of the mucous membrane and the mucus it produces are lessened, and the mucosa stays moist. The normal change from positive to negative pressure with exhalation and inhalation, which is absent from the nose in ozena is restored and improves the circulation of the blood. The establishment of adhesions between the septum and the turbinates creates new anastomoses in the circulation of the blood.

Staphylococcal Infections in Diabetes Mellitus—Gilchrist and Wilson point out that diabetic patients in the region of Toronto treated with staphylococcal toxoid show definite improvement, in spite of adverse weather conditions, in all tests that were used as criteria. This is the first time that they have been able to observe this in the winter months. They have been able to substitute a weekly dose of staphylococcus toxoid for various daily doses of insulin. The diabetic patients on insulin have all shown a reduction of insulin dosage, the rate of fall being dependent on the amount of focal infection and dampness. The authors are convinced that in most diabetic patients they are dealing with a staphylococcal factor and that by using toxoid the cause is attacked. They have been afraid to use the antitoxin because of the tremendous alterations that may occur in the diabetic state through an increase in the basal metabolic rate.

Bacteria Isolated from Stools of Healthy Food Handlers—Kriebel isolated twenty-nine strains of gram negative non-lactose-fermenting intestinal bacteria from a group of healthy food handlers during a routine carrier examination. These strains produced non-lactose-fermenting colonies on eosin-methylene blue plates and on Russell double sugar, resembling the paratyphoid group. None of the strains fermented 1 per cent lactose solution in forty-eight hours, though they all fermented a considerable number of other carbohydrates. The organisms could be divided into seven groups by sugar fermentation reactions. Some groups showed identical strains. Twenty-five strains produced indole, and twenty-one strains were nonmotile. Agglutination reactions with serums of established pathogenic types were negative. Continued growth in 5 per cent lactose solution resulted in varying degrees of dissociation into lactose-fermenting variants, some of which produced typical colon colonies when plated on eosin-methylene blue agar. The chief importance of these bacteria lies in their confusing resemblance to the pathogenic intestinal organisms on the first differential mediums. The conclusion is drawn that these strains are closely related to the colon group, possibly as variants since they tend to dissociate into lactose-fermenting coli-like organisms.

Treatment of Osgood-Schlatter Disease with Drill Channels—Bozsan and O'Kane have applied drill channels for treatment of Legg-Calve-Perthes disease and of intra capsular fractures of the neck of the femur with the expectation that the fresh blood supply conducted to the diseased areas of bone would facilitate and hasten the process of repair. A small incision or stab wound is made over the affected tibial tubercle and one or two channels are drilled through the diseased area indicated on the roentgenogram into the cancellous upper end of the tibia. Immobilization in casts appears to be unnecessary. The patients are allowed to walk as soon as they are able to do so without pain. The authors treated six cases in this manner with prompt results. The clinical symptoms subsided within from three to four weeks and complete bony restoration has been demonstrated by roentgen examination as early as seven weeks after operation. During this time pain and swelling have disappeared, the patients have regained confidence in the extremity and have been able to assume a squatting position. The authors stress the fact that they recommend this operative procedure only for cases in which the handicap is severe and there has been long continued serious annoyance with recurrent attacks of pain over a long period of time and for instances in which one or more years elapse before the symptoms subside entirely.

Effect of Sympathectomy and Venous Stasis on Bone Repair—McMaster and Roome point out that the increased arterial hyperemia resulting from lumbar sympathectomy did not hasten the repair of bone in their experiments. In half of the experiments in which complications did not occur, healing was actually retarded as judged by comparison with the nonsympathectomized side. The results of these experiments, as well as of those of Pearse and Morton and of Key and Moore, cast doubt on the advisability of doing any type of sympathectomy in an attempt to hasten bone repair. The results of the authors' experiments, in which venous stasis hastened the repair of bone, confirm similar observations made by Pearse and Morton. In clinical synovial tuberculosis, hemangioma of the leg, Brodie's abscess of the upper end of the tibia, giant cell tumor of the tibia, femoral and iliac thrombosis, recurring hemarthrosis of the knee in cases of hemophilia, chronic osteomyelitis of the femur, severe trauma to soft parts with resultant and prolonged infection and ulceration, and fracture of the femur, as well as in the experimental work there occur all stages of congestion from a sluggish circulation to a marked venous stasis. Hence it appears that bones grow more rapidly and heal more promptly in the presence of venous congestion. Following lumbar sympathectomy there is present an arterial hyperemia with an increased blood flow. Consequently this operation would not be expected to stimulate bone growth or repair.

Internal Fixation of Transcervical Fractures of Femur—Wescott states that in cases of transcervical fracture of the femur immediately on admission to the hospital a Buck's extension is applied to prevent muscle spasm and overriding of fragments and to lessen shock. The forward angle, or angle of anteversion, is determined by means of a portable x-ray machine. The exact length of the nail necessary to fix the fragments is ascertained. The point of the blades must penetrate the proximal fragment deep enough to give stability without encroaching on the cartilage. The head of the nail should extend one-fourth inch beyond the cortex to facilitate the extraction of the nail at a later date. From twenty-four to forty-eight hours later, without releasing the pull of the Buck's extension, the patient is removed to the operating room. A flat Buck's diaphragm or tunnel is placed under the fractured hip and the x-ray tube is centered over the hip. Under an anesthetic the Buck's extension is removed and the fracture is reduced by internal rotation and gentle flexion of the femur at the hip. This manipulation is repeated two or three times. During flexion, sufficient traction is made to counterbalance the weight of the thigh. The leg is extended in internal rotation. Stereoscopic roentgenograms are made to prove reduction. If reduction is complete, an incision from $2\frac{1}{2}$ to 3 inches long, is made over and below the trochanter. One-half inch below the vastus muscle, a small hole is bored into the bone and narrow slits are made with an osteotome to receive the blades of the nail. The roentgenogram protractor is placed over the roentgenogram taken after reduction, with its base along the shaft, one-half inch below the vastus muscle and the lever is made to correspond with the center of the neck of the femur. The reading of the number of degrees of angulation of the neck with the shaft is made and the bone protractor is set at a like angle and clamped. The nail is driven into the flattened neck of the femur at the angle indicated by the lever of the bone protractor. The fracture is impacted and the wound is closed. Stereoscopic roentgenograms may be made if desired to check the course of the nail. The author used this procedure in twelve cases irrespective of age or general condition. In spite of the fact that several of the patients were poor surgical risks, there were no deaths that could be attributed to the operation or its after-effects.

Calcification in Fat Pads About the Joints—Ferguson cites four cases of calcification in fat pads about the joints in which roentgen examination revealed a flaky, calcareous mass. The calcareous particles appeared as short rods or dashes, which are believed to be characteristic of calcification in fat pads at the joints. The particles later became nodular and less rodlike in form. In two cases the calcareous mass was demonstrated by roentgenograms to be altered in shape and in relation to the bones by pressure and by change of position.

The fat pad was removed at operation in two cases. In one, of short duration the calcareous material dissolved in the fixing solution (formaldehyde) and the specimen was fat. In the case of longer duration the fat pad was extensively converted into masses of cartilage, with small areas of ossification. In three of the cases the onset of symptoms was preceded by trauma. In the fourth case the patient was not examined until one year after onset and she did not remember any injury. In each case only one joint was affected and the symptoms were mild, consisting of slight limitation of motion and moderate pain on use of the joint or on forced motion.

Culture of Sterile Maggots for Surgical Use—Robinson and Simmons investigated the tolerance of the egg, maggot prepupa and pupa to various periods of retardation in the production of surgical maggots. Eggs may be kept in a closed container in a refrigerator at from 40 to 43 F for twenty-eight hours with a mortality only slightly greater than normal, but continued storage is unfavorable and in three days results in almost complete destruction. The age of the egg when stored affects the degree of injury. The lowest mortality occurred when eggs were allowed to remain in the warm incubator an additional two or three hours after they were removed from the fly cages before being stored. Surgical maggots cannot be kept satisfactorily in cold storage. After a retardation of twenty-four hours only 40 per cent were able to resume feed-

ing, and in six days almost 100 per cent destruction occurred. The authors describe a retarding food which eliminates the need of cold storage during the sterility tests. Prepupae are best adapted to cold storage, but even in this stage the possibilities are considerably limited. They lose weight and become shrunk during cold storage. This is mostly water loss. Least unfavorable results were obtained with a relatively air tight container. In thirty-three days the mortality was from 33 to 46 per cent and in seven weeks it had increased to approximately from 38 to 55 per cent, depending on the method of storage. When prepupae were stored from three to four weeks, the females that emerged were permanently injured and their egg-laying capacity was much reduced. Pupae are unable to withstand even a moderate period of retardation. After the second week the mortality rose to about 66 per cent, and most of the eggs laid subsequently failed to hatch. Low temperature retardation of the various stages in the life cycle of the blowfly, although a convenience in cultural technique, causes such a high mortality that its use is considerably limited.

Light Filtering Index of Blood Serum—Rohdenburg and Schleussner point out that if light of differing wavelengths is passed through nonhemolyzed blood serum a definite absorption of the available light occurs. They term the rate at which the light is absorbed, when calculated for bands 100 angstrom units in width, the "light filtration index." In normal persons this index remains fairly constant over periods as long as fifteen days, minor variations occurring in consequence of simple physiologic disturbances, such as constipation and menstruation. The normal index varies between 1 and 31, with an average of 21. The index is affected by the parenteral injection of foreign proteins, by the ingestion of colloids, such as dyes, and probably by other factors. In pathologic conditions associated with fever the termination of the fever is characterized by a sharp drop in the index and convalescence by a steadily rising index. An index that remains between 22 and 26 is of good prognostic import, as is a steadily rising index. A consistently low index is of bad prognostic import. The Pulfrich photometer is employed, equipped with two filters having as their center of light filtration wavelengths (plus or minus 100 angstrom units) of 7,200 and 4,300 angstrom units. A standardized cell having a depth (thickness of serum layer) of 2.5 mm is used and this cell is so constructed that the width of the serum layer is 3 mm. The portions of the cell that are not actually the walls of the cell cavity are painted black. Blood for examination is collected in a Wright capsule after finger puncture. To give a sufficient amount of serum the body of the capsule should be 3.5 cm in length and the bore approximately 8 mm. Hemolyzed serums should be discarded. Specimens should be collected at the same relative time of day. After the serum is separated from the clot it may be examined at any time within twelve hours. The standardized cells of the photometer are filled, one with distilled water and the other with the serum to be examined. The amount of light that is passed by the serum with each of the specified filters is determined. The reading obtained with the 4,300 angstrom filter is subtracted from that obtained with the 7,200 angstrom filter. The result thus obtained indicates the amount of light of the band situated between the central points of the two chosen filters that has been blocked out. This result is then divided by the number of 100 angstrom units present in the band, i. e., 29.

Preoperative Skin Sterilization—Richardson states that the technic of preoperative skin sterilization now in use at the University Hospital is as follows. The skin is shaved the evening before the operation, scrubbed and washed with tincture of green soap for five minutes, wiped with benzene on gauze and with ether and gauze, and a sterile alcohol dressing is applied and held in place with a sterile towel and binder. On arrival in the operating room the skin is painted with two coats of 35 per cent tincture of iodine and allowed to dry. A saturated solution of sodium thiosulphate in 70 per cent alcohol is sponged liberally over the painted area and allowed to remain a few seconds. From three to four sponges liberally saturated with the solution are used. This removes practically all the iodine and leaves the skin white. The skin is then dried with sponges and is ready for incision. This method has been in use for ten years and has proved useful and has not been accompanied by bad results.

Thyroidectomy in Chronic Lymphatic Leukemia — Dameshek and his associates present the case of a woman aged 42, with the signs of aleukemic lymphatic leukemia, who had a basal metabolic rate of plus 65 per cent. It was thought that the continued loss in weight, profuse drenching sweats increasing nervous symptoms and beginning circulatory failure might be due to the markedly elevated metabolic rate. When the patient became extremely ill and failed to respond to rest in bed, compound solution of iodine and roentgen therapy, complete ablation of the thyroid was performed. Following this procedure the metabolic rate dropped strikingly and the clinical signs and symptoms of hypermetabolism disappeared, as did the signs of circulatory failure. The patient gained weight, and the lymph nodes and spleen regressed about 90 per cent from their original size. There was complete disappearance of all symptoms and the blood picture became almost normal. Improvement has continued for five months after thyroidectomy. The authors state that remissions have been frequently reported in this disease and it is possible that the improvement is due to a remission. The rapid onset of improvement after the treatment leads them to believe, however that the operation was at least partly responsible for the improvement. They do not recommend this form of treatment for other types of malignant disease.

Effect of Alum-Precipitated Ragweed Pollen Extract — Harrison found alum-precipitated ragweed pollen extract to be an effective sensitizing agent in guinea-pigs. This solid form is much more effective than the same amount of extract in aqueous solution. Guinea-pigs with the precipitated extract in the abdominal wall for ten days were sensitive to a large dose given intravenously. It is probable that the slow absorption of precipitated pollen extract more closely approaches the natural method by which human beings become sensitive to plant pollens. The addition of alum, in a concentration as high as 0.3 per cent, to ragweed pollen extract does not interfere with its desensitizing properties. It is possible that this small amount might slow the rate of absorption sufficiently to permit injection of larger doses in hypersensitive persons.

*Roentgen Therapy in Metastatic Bone Cancer Report of Four Cases J Roemer, Paterson N J —p 499

Roentgen Therapy in Metastatic Bone Cancer —Roemer reports four cases of metastatic bone cancer and states that metastatic foci may be present in bones without presenting clinical evidence; therefore routine roentgen examinations should be made of the skeleton, especially of the pelvis and spine in all cases of cancer of the breast. The author's cases responded favorably to high voltage roentgen therapy. The patients were made comfortable and were able to perform their household duties. Life can be prolonged by this method for several years. Much better results might be accomplished if such cases were subjected to roentgen radiation as soon as clinical symptoms presented themselves, in spite of negative roentgen observations. The author uses 215 kilovolts 4 milliamperes, filtered with 0.75 mm of copper and 1 mm of aluminum, at 50 cm focal skin distance. With these factors the erythema dose is eighty-six minutes when a portal of entry 20 by 20 cm is used. Daily treatments are given if possible. In most instances one half erythema dose is given to one portal of entry at each session.

Radiation Therapy of Renal Cortical Neoplasms—

Waters and his associates point out that tumors of the hypernephroma type and embryonal carcinomas are sensitive to roentgen rays. Papillary carcinomas of the renal pelvis and the malignant papillary cyst adenomas are resistant to roentgen rays. Irradiation has caused a striking reduction in the size of roentgensensitive renal tumors and produced extensive morphologic changes in sensitive tumors with extensive fibrosis, hyalinization and necrosis. In certain cases the tumor has been almost completely destroyed and replaced by fibrous tissue. Normal renal tissue has not been injured by irradiation in the dosage employed in the authors' cases. Palpitation of the tumor should be avoided as much as possible to prevent expressing tumor cells into the blood stream. Tumors that were inoperable because of their great size have been rendered operable by shrinkage following irradiation. Reduction in the size of sensitive tumors begins almost immediately after the institution of irradiation. The authors recommend operative removal of the tumor after completion of the first series of irradiation (approximately three weeks), allowing a few days for rest and transfusion if the degree of anemia justifies it. A regrowth of the tumor may occur if operation is delayed long after completion of irradiation. Preoperative irradiation has not made operation more difficult and in certain cases has simplified nephrectomy. The renal pedicle should be ligated before the tumor is freed, thus diminishing the risk of metastasis.

Anesthesia—Poe believes that open ether inductions of anesthesia should be dispensed with (except in infants), because of the dangers of acapnia, apnea, excitement and struggling. It perpetuates the dread of anesthesia and thus materially hinders the progress of surgery. The induction of anesthesia with nitrous oxide gas-oxygen, changing to ethylene after consciousness is lost, with or without the addition of ether as may be required and with proper narcotic premedication, is the safest and most useful of all general anesthetics known. With the maintenance of sufficient humidity in the bag which is not difficult, ethylene is safe from static ignition, regardless of its proportion with oxygen in the moisture filled bag. To discard the use of ethylene in surgery would be analogous to discarding gasoline in present-day transportation. Ethylene, however, should be administered only by those well instructed in its use. Surgeons and dentists should have a working knowledge of anesthetics, and modern anesthesia should be administered only by those who are specially trained.

Precancer of the Cervix Uteri—Freedman made a histologic study on sections of precancer of the cervix so as to demonstrate the points of relative similarity between it and the earliest cancers—this similarity causing a confusion in diagnosis and a lack of finality about the existence, orientation or description of precancer. The following conclusions seem warranted: 1 Evidence goes to prove that in the cervix there does exist a precursory stage of cancer, the 'precancerous' or preferably the 'carcinoid stage.' 2 Cancer is definitely present and can be diagnosed in the cervix from the altered cytology alone, even when there is not the slightest down growth and the basement membrane is intact. 3 Many of the carcinoid conditions that are found in the neck of the uterus as a result of chronic irritations show an altered cytology which is comparable to that found in the genuine cancers, consequently there is much confusion as to the proper diagnosis. 4 Although there are not to be had unassailable scientific histologic criteria for carcinoid conditions, there still is a satisfactory means of diagnosis of the condition in the cervix, viz (1) the general appearance is not suggestive of established cancer, (2) few actual cancer-like cells are present and these are single and detached, (3) these altered cells are surrounded and separated by too many normal cells usually similar in type and (4) there is little or no loss of polarity. 5 An attitude in general that cancer may be mimicked perfectly histologically and still cancer not be present is a mistake and dangerous one. There is no doubt that many such cases are really cancerous. 6 Vital stains (Schiller, Ludford) offer a suitable method of diagnosing the earliest actual cancers and of differentiating them from carcinoid conditions. 7 For the final histologic diagnosis of suspicious tissue, in addition to vital staining, there is required biopsy examination with the microscope. The biopsy should be cut transversely and sectioned serially for microscopic study, and there must be repeated removal of tissue for examination if necessary.

Anesthesia for Toxic Goiter Patients—The Bartletts have the toxic goiter patient, under the partial influence of a basal anesthesia, placed on the table and the four sites of injection marked with pen and ink. Points for injection are determined as follows. The posterior border of the sternomastoid muscle is marked the ends of which are placed on the appropriate anatomic landmarks on the skull and clavicle, the distance between these two points is determined, the anterior border of the sternomastoid is determined and marked along a 'straight edge,' and a cross mark is made at a point slightly lower than that on the posterior border of the muscle about on a level with the laryngeal tubercle and just above the lower border of the thyroid cartilage. The skin of the neck is cleansed with benzine and sterilized by spraying with sodium ethylmercurithiosalicylate (merthiolate). A light gas anesthesia is started and carried to the depth at which needle

pricks will not be noted. Then through the posterior of these two injection points the portion of the superficial cervical plexus is blocked which curves around the posterior margin of the sternomastoid at its middle, about 3 cc of a 2 per cent solution of procaine hydrochloride without epinephrine being used, thus securing approximately a one hour anesthesia of the skin and fat. It is necessary to anesthetize the three ribbon muscles as well as the fasciae covering them and connecting the two across the midline. This can be accomplished through the anterior injection point by blocking the branches of the descendens hypoglossi where the three separate. A needle can be inserted into this space through the opening in front of the sternomastoid at a little lower level than that on the posterior border, a like amount of the same drug being used. The incision is made, the mask is removed and no more gas is employed unless the patient demands it. Each upper pole is infiltrated after its exposure with a 2 per cent solution of procaine hydrochloride just before it is divided. Thus is a painless bilateral resection operation ensured after needle thrusts, four of them made prior to skin incision, and the fifth and sixth after the upper thyroid poles are exposed.

Fusion of the Tibio-Astragaloid Joint—Wescott attempted to fuse the tibio-astragaloid joint by the removal of a sufficient amount of bone in both the tibia and the astragalus to result in a better blood supply without shortening the extremity and thus producing a complete mortise from inside the joint. During the operation, the foot is held by an assistant in plantar flexion of 5 degrees for men and 15 degrees for women. Through an incision over the internal malleolus, a block of bone is removed extending through the joint, one-fourth inch in width and from one-half to three-fourths inch in height. This opening with the three-fourths inch axis in line with the shaft of the tibia, is extended through the ankle joint, its upper half in the tibia and the lower half in the astragalus. It is carried into the fibula until its inner half has been entered and the small block of bone removed. A graft is taken from the tibia of sufficient width to fill the greater diameter of the tunnel and twice the length of the depth of the tunnel through the joint. The graft is divided at the center of the length and placed cortex to cortex to double its thickness. The two pieces of graft are driven in as one, through the opening in the malleolus and through the joint into the fibula. External fixation is unnecessary, as the graft acts as a key.

Operation for Cure of Ascites—Fraser discusses an operation that was performed in an intractable case of ascites in which other treatments had failed. It was attended with

instantaneous relief. The omentum was split into halves from its free border to its root, and each half was carried between the muscles of the anterior abdominal wall and anchored there by sutures. The wound healed by first intention, but paracentesis had to be performed eleven days later in order to save the scar from bursting open from distention. This first operation was a complete failure. Throughout the following month, paracentesis had to be performed repeatedly. The author wondered whether the procedure adopted in the radical treatment of hydrocele would have the same beneficial results in ascites. So for the second operation an incision running from just above the pubes to well above the umbilicus was made and the peritoneum on each side of the wound was stripped up by gauze dissection nearly to its reflection on to the ascending and descending colons, the general oozing of blood was arrested easily by hot saline gauze swabs. The abdomen was then closed with a continuous silk suture and no drain was put in. A small dose of morphine was given prior to the operation to abolish any chance of shock. The wound healed by first intention.

Unusual Form of Tuberculosis—Goyle and his associates cite a case of tuberculosis of the liver, spleen and lymph nodes. The gross appearance of the liver at first sight suggested secondary carcinomatous growths though there was no characteristic central umbilication, but on histologic examination it was clear that the lesions were of the nature of an infective granuloma. Even though the firm, elastic, cheesy consistency of the lesions and the infrequent concentric formation of endothelial cells were suggestive of multiple gummas the absence of definite fibrous capsule and cicatrices the negative Wassermann reaction, and the presence of Langhans type of giant cells, especially in sections of glands and spleen were all in favor of tuberculosis. Definite proof of the lesions being tuberculous in nature was afforded by the demonstration of acid-fast bacilli in sections of the liver spleen and lymph nodes. The bacilli being few, they were demonstrated only after careful examination of a number of sections. Histologically, the lesions were unusual in that giant cell systems, such as are found in tuberculosis, were rare except in the lymph nodes and the spleen.

Healing of Intraduct Carcinoma of the Mamma—Muir and Aitkenhead report two cases of Paget's disease of the nipple in which the associated intraduct carcinoma has at places

undergone retrogression and disappeared. This occurs by reactive change in the connective tissue within the elastica, which undergoes hyperplasia and, as the cancer cells atrophy, produces obliteration of the lumen. The obliterated ducts ultimately are represented by hyaline material, often avascular and relatively acellular, surrounded by a ring of abundant elastic tissue. These changes have been observed mainly in the ducts in the deeper part of the nipple and in the subjacent tissue, and also in the substance of the breast.

Atheroma and Coronary Thrombosis in Diabetes—Cullinan and Graham present a case of relatively mild diabetes and widespread arterial atheroma with coronary thrombosis, with death at the age of 27. The cause of the arterial damage could not be determined. The incidence of arterial degeneration and the knowledge that the blood cholesterol was raised were two of the factors that led to the recent introduction of a diet richer in carbohydrate and poorer in fat for the treatment of diabetes. In the authors' case the cholesterol content of the blood was not estimated. Also the relationship between exogenous cholesterol and atheroma is far from clear. It is possible by cholesterol feeding to produce atheroma-like lesions in rabbits and sometimes in rats and mice but not in cats or dogs, and it is almost certain that carnivora have means of dealing with cholesterol which herbivora lack. It may even be that atherosclerosis in the human being is associated with an upset not of the exogenous but of the endogenous metabolism of cholesterol.

Giant Cell Formation and Caseation in Tubercles in Liver—Day observed the reticulum associated with miliary tubercles in the human liver to be either a new formation associated with healing or the remains of that which supported pre-existent liver cells. The presence of reticulum similar in arrangement to that of the normal liver in situations from which all trace of liver cells had disappeared is considered to indicate a previous necrosis. Such reticulum was present in 90 per cent of the lesions examined. It was best seen in caseous material, and it intimately surrounded the majority of giant cells. The author concludes that necrosis must in many cases have preceded giant cell formation and he presents evidence to show that the substance of giant cells differs from caseous material.

Fluid Factor in Treatment of Neglected Diabetic Coma—In treating dehydration of neglected diabetic coma, Byrom treats the case as one of profound shock. The patient must be kept warm. Immediately after admission he is given from 50 to 100 units of insulin intravenously, followed by 500 cc of warm physiologic solution of sodium chloride. Meanwhile, dextrose to last the patient for twenty-four hours (usually about 500 Gm) is dissolved in about 2 liters of half strength physiologic solution of sodium chloride, which is given to the patient by mouth in twenty-four equal doses, accompanied by subcutaneous injections of suitable doses of insulin. As a rule from 10 to 20 units is injected every hour until the blood sugar, which is estimated hourly, has fallen to normal. The patient is encouraged to drink freely half strength physiologic solution of sodium chloride. When this solution is used, both salt and water are almost quantitatively retained and little is excreted. The dextrose and saline mixture is well

tolerated by the patient and seems less prone to cause vomiting than dextrose dissolved in water. It should be given in small mouthfuls. If the patient cannot be roused after the first intravenous injection care should be taken if further infusions are necessary to see that the fluid is injected slowly enough to permit diffusion into the tissue spaces without burdening the heart. This routine should be suspended as soon as clinical evidence of dehydration disappears.

Value of Blood Serum in Septicemia—Lazarus-Barlow and Chamberlain gave twelve patients whose diagnosis was septicemia or sapremia an intramuscular injection of antiserum and, if no improvement took place within twenty-four hours as judged by a fall in the temperature and pulse rate, an injection of fresh human serum was given. If further antiserum was considered necessary, it was almost always given alone, and the human serum twenty-four hours later. In all cases in which streptococcus antiserum was administered, the polyvalent and antiscarlatinal antisera were used in equal proportions. In certain cases some of the serum was given intravenously—after it had been found compatible with the patient's red cells—and the remainder intramuscularly, so as to carry on the effect. In other cases the whole amount was given intramuscularly. To obtain the serum, approximately 50 cc of blood was withdrawn from the vein of a donor and centrifuged as soon as it had clotted, the separated serum was then injected into the patient at once, usually about half an hour after its withdrawal. In the series of the twelve cases there were only three deaths. In one, death was due to thrombosis of the inferior vena cava, but immediately after the administration of the human serum and up to the onset of the thrombosis there was distinct improvement. In the second case the patient was an elderly woman with, presumably, an acute staphylococcal septicemia—a condition for which there was no satisfactory antiserum at the time. The third patient died of meningitis but there was a definite improvement in the temperature after the administration of the human serum, and the complete absence of further rigors was a conspicuous feature. In some cases the second dose of antiserum produced a fall in temperature without the subsequent injection of human serum, whereas no effect had been produced by the first dose until after the addition of the human serum. In several cases one effect of the human serum appeared to be that the patients obtained longer periods of sleep. Another noticeable effect was an improvement in their general condition within twenty-four hours whether the temperature had fallen or not. The authors conclude that from the clinical point of view whole blood would be at least as effective as serum, making the method available to the general

practitioner who has not the apparatus at hand for the separation of the serum.

Systemic Poisoning by Phenylenediamine—Israels reports a fatal case of systemic poisoning by phenylenediamine in which the history, the appearances in the liver, the absence of other causes (the ascending infection in the kidney was almost certainly terminal), and the known toxicity of the dye make it a reasonable supposition that subacute atrophy of the liver was due to the use of the dye. The author believes that the use of hydrogen dioxide for removing the dye from the hands was a contributory cause in this case. It seems likely that the production of aniline is responsible, at least in part, for the toxic symptoms. The dye as used commercially is a mixture of the meta and para forms of phenylenediamine. Deamination of either of these gives aniline. Support for this hypothesis was found in the occurrence of pale blue staining material in the liver. The symptoms of Nott's case are strongly suggestive of aniline poisoning.

Red Cell Diameter and Volume—Vaughan and Goddard made forty comparative determinations of cell volume and cell diameter. In clinical practice the size of the red cell is judged by whether the estimated mean falls within, below or above the normal limits. The volume and diameter were considered to be correlated when the means of both fell within, below or above the range of means observed to be normal for volume by Wintrobe and calculated to be normal for diameter by Price-Jones. They were considered not to be correlated and one to be greater than the other when one fell outside the normal limits. In a miscellaneous group of twenty-one cases there was a correlation between the values for mean corpuscular volume and mean diameter. In a group of five cases, all of acholuric jaundice, the mean diameter was less than the mean corpuscular volume—i.e., the cells appeared to be thicker than normal. A group of six miscellaneous cases gave a greater mean diameter than the mean corpuscular volume—i.e., the cells appeared to be flatter than normal. Their results agree with the more numerous observations of others, that for clinical diagnosis volume can be taken as a measure of cell size in Addisonian pernicious anemia and in idiopathic hypochromic anemia. The series shows, however, that it cannot be so taken in all anemias. Estimation of cell volume is necessary for calculation of mean corpuscular hemoglobin and mean corpuscular hemoglobin concentration per cubic centimeter. The latter will possibly prove of diagnostic value. It is also necessary for comparison with measurements of cell diameter in order to recognize changes in the thickness of red cells. The results agree with the observations of others that in patients with acholuric jaundice the red cells are characteristically abnormally thick, the mean corpuscular volume being greater than the mean diameter. The average mean corpuscular hemoglobin concentration in acholuric jaundice patients was found to be greater than in the eight normal controls. It is suggested that this finding is associated with the discrepancy between cell volume and cell diameter.

 Contribution to Study of Tuberculous Infection in Infancy and Childhood J C Hendrie—p 264

The Platelet Count in Tuberculosis—Brock describes the behavior of the platelet count in the course of tuberculosis. In general there is a rise in the number of platelets when the disease is active, and a return to normal figures follows a subsidence in the activity of the process. The raised count is more an index of activity than of prognosis, but as a corollary it may be of value in prognosis. When the infection is particularly severe the platelet count may fall to low figures, an event of as grave significance as is a fall of the leukocyte count during an acute septic process. The rise is so constant as to be of some value in the diagnosis of doubtful cases. The author discusses the relationship of this rise to the occurrence of spontaneous venous thrombosis during the course of the disease and shows that the behavior of the platelet count after the major operation of thoracoplasty follows a different course, which is the course usually observed after any such major operation. This suggests that one must be careful before assigning undue importance to the thrombocytosis, especially in connecting it with the process of immunity. It is possible that the reaction may only be a secondary minor result of circulating toxins of any sort and be in no way connected with the more important defensive mechanisms.

Chronic Epyemas of Gallbladder and Appendix—Muir describes two cases, one of chronic epyema of the gallbladder and one of chronic epyema of the appendix. The infective process in the two cases was similar in that catarrhal inflammation of a mild degree of virulence was present, associated with obstruction to the drainage of the products of inflammation in the case of the gallbladder by an impacted calculus, and in the case of the appendix by torsion of the proximal end, which obstructed the lumen. The inflammatory material after a certain time became sterile, owing to the low virulence of the causal bacteria and their subsequent death through the accumulation of metabolic products in the inflammatory fluid. No acute symptoms arose in the first case, although almost complete destruction by ulceration of the mucous membrane of the gallbladder and atrophy of the appendicular mucous membrane with little ulceration must constitute rare pathologic phenomena in infective processes of the organ.

 Application of Rehberg's Theory to Clinical Study of Renal Disturbances and Diabetes P Cambier—p 273
 *Role of Hepatobiliary Factor in Origin of Hypertension J Daniel—p 300

Use of Bile in Treatment of Hypertension—Vasomotor substances in the body can be divided into two antagonistic groups: the hypertensive group represented by epinephrine and the hypotensive group represented by histamine, acetylcholine and adenylic acid. Daniel believes that a route of elimination of the vasomotor substances is by the hepatobiliary tract. He and his co-workers have verified the hypotensive action of bile, which they believe is simply a physiologic attribute and not an argument in favor of the toxic nature of bile. Experiments were performed on twenty dogs anesthetized with a barbitol derivative. Human bile from three sources, ox bile, bile of swine and of dogs, and sterile ox bile were used. Whether injected intravenously or intra-arterially all these substances produced a marked, immediate and lasting drop in arterial pressure. The experiments could be repeated many times on the same dog. After a drop of certain duration the arterial pressure always returned to its initial level. Slight acceleration of the pulse and slight modification of the respiratory movements occurred. The intensity and duration of the hypotensive effect were proportional to the amount of bile injected. The author feels that the factors in the bile responsible for this action are uncertain. Sodium glycocholate and sodium taurocholate have a hypotensive action, but less accentuated and lasting than that of bile. It was found further that in a gravid and hypertensive dog injection of autogenous vesicular bile caused a drop in arterial pressure. This action was less pronounced by a similar injection in a normal animal. In seventeen patients with arterial hypertension without demonstrable renal lesions, clear ox bile was administered by mouth for ten days in a dose of from 15 to 3 Gm a day. In ten of these a marked and lasting drop in tension varying from 40 to 60 mm occurred. In five others the drop was less, but the subjective effect was good. In two cases there were no results.

Disturbances from Dechloridation—Ambard and his collaborators attempted to produce dechloridation in two dogs without dehydration, other than that due directly to the change in salt concentration. The dogs were fed a soup consisting of saltless bread, potatoes and meat, and drinking water as desired. By this regimen the plasma chlorides fell to 39 per thousand. To produce a further drop in chlorides they injected from 1 to 2 mg of histamine to cause gastric secretion and a half hour later injected a few centigrams of apomorphine to produce vomiting. In this way dechloridation was produced by way of the stomach. This procedure was repeated two or three times a day for two weeks and the plasma chlorides were reduced to 25 and even 225 per thousand. The effects of dechloridation were studied in this manner over a period of eight consecutive months. The principal observations were a rise in alkali reserve, so that it was doubled as the plasma chlorides dropped from 4 to 225 per thousand; dehydration of the blood, demonstrated by an increase in plasma albumin up to 30 per cent of its normal value, no appreciable effect on the aqueous secretion of the kidney, marked disturbance of urea secretion, which in the course of a drop of blood chlorides to 225 per thousand tended to drop in maximal concentration to a third of its normal and elevate the level of blood urea to triple its normal, little modification of appetite diminished but not abolished gastric secretion (produced by histamine). There were no appreciable

modifications of the general condition even when the blood chlorides were kept between 22 and 3 per thousand for nearly two consecutive months

- Extra Articular Arthrodesis of Knee by Anterior Route in Children A. Delahaye—p. 515
- *Late Results of Nephropexy by Shortening Renal Fascia N. Kleiber—p. 521

Blood from Nipple in Ectasis of Galactophores—Generalized dilatation of the milk ducts causing bloody secretion from the nipple is rare. Moulouguet and Rousset cite seven cases, two of which were observed by them. The condition is to be recognized by hemorrhage coming from numerous duct pores and the absence of a solid or cystic mammary tumor. The discharges are usually intermittent. The authors stress the elimination of other causes before this diagnosis is made. These cases may be divided into two types. The first is associated with quiescence or even atrophy of the glandular apparatus. In this type enormous canals are seen, sometimes distended and sometimes long and tortuous, with blood or bloody coagulum in their lumens. In the second group the dilatation of the ducts is less marked and coexists with an active glandular apparatus. In neither group however, is the least sign of malignant growth apparent. Treatment, therefore, should not involve the mutilation of a radical breast removal. The authors' operation of choice is removal of the mammary gland by subcutaneous operation with the radial incision suggested by Lecene.

Results of Nephropexy—According to Kleiber, two groups of factors are responsible for retaining the kidney in its normal position. The most important are the anatomic means of fixation. Less important are the influences of abdominal pressure, full loops of intestine, the aspirating effect of the diaphragm, and intraperitoneal pressure. The renal fascia is the principal means of holding the kidney in position in the manner of a sack. In cases of floating kidney the planes of the fascia separate, allowing the kidney to sink between them. Forty nephropexies have been performed by the author. The technic involved typical lumbar incision and exposure of the renal fascia through section of the musculature and the fascia transversalis. After section of the renal fascia longitudinally the kidney is freed from adhesions and replaced in normal position. The fascial sac is closed with reefing sutures. To obtain the best possible adhesion of the kidney to the surrounding tissues, the author has practiced decapsulation before closure of the sac. In follow up studies of eighteen patients from two to seven years after the operation, subjective results were good. In none was the replaced kidney palpable. Roentgenologic control by pyelography in most of these patients showed the kidney to be well fixed and in good position.

- Syphilis and Paralysis of Dilators of Larynx M. Jacod—p. 538

Roentgen Therapy of Algeias—Haguenuau and his associates report the results of treatment of so-called essential algeias with roentgen therapy. Only ultrapenetrating roentgen rays were used since the authors had never seen a case refractory to the ultrapenetrating rays respond in later treatment to rays of less penetration. After many attempts they standardized their technic as follows: constant tension of 200,000 volts, filters of 1 mm of copper and 0.02 mm of aluminum, anticathode skin distance of 40 cm, total doses of 3,000 roentgens for each field of irradiation divided into biweekly treatments of 500 roentgens. If the results are not satisfactory,

the same treatment under the same conditions may be repeated after a rest of three or four weeks. They irradiate as wide a field as possible (while protecting the important organs) and filter the rays with a heavy metal (copper or zinc). Their results are based on patients treated more than two years ago in order to insure the durability. In sciatica (divided into high, middle and low types), which had been refractory to all other forms of treatment, roentgen therapy was quite effective. Of thirty-one cases treated by the authors, fifteen showed frank and lasting cure, seven definite amelioration and nine no results. In ten cases of cervicobrachial neuralgia there were six cures, two ameliorations and two failures. In essential neuralgia of the trigeminal, roentgen therapy gives poor results, but in facial causalgia the therapeutic effects of roentgen rays are especially favorable. In posttraumatic and postoperative algeias there are many failures, but results are better than with other forms of treatment. Roentgen therapy in talalgias, with or without calcaneal spur formation, usually gives good results. In two cases of coxalgia the authors obtained one cure and one slight amelioration. Of nine patients treated during the course of herpes zoster, there were seven cures, one amelioration and one failure. In certain other miscellaneous algeias, roentgen treatment gave inconclusive results. The authors conclude that in many refractory cases roentgen therapy is of definite benefit, though its employment is still mostly empirical.

- Stuttering Its Development and Treatment According to the School of Fröschels in Vienna Mlle. Mussafia—p. 510

Treatment of Roentgen Dermatitis—Craps and Alechinsky advocate a simple technic consisting in protecting the healthy tissues with a screen of linen, pomade or tissue paper and painting the lesion lightly with a 5 per cent aqueous solution of silver nitrate. In some cases to insure adherence of the solution and to facilitate its absorption it is advantageous first to wash the affected area with ether and it is often necessary to clear the skin of squamas or less adherent crusts before application of the solution. The area is then exposed to a quartz lamp at an optimal distance of 20 cm. The period of irradiation varies from five to ten minutes. In all cases it must be sufficient to produce complete drying of the solution and blackening of the area. If the color is not dark enough the area is repainted until it becomes a glistening black. Since drying of the lesion begins from the time of the first application, the area treated should be covered only with a sterilized gauze compress. No fatty substances should be applied in the course of treatment. The patient is treated every other day. The authors studied five patients, all of whom responded well to treatment. Pains disappeared after one or two applications. Scar formation was rapid. The period of treatment in general was shorter than that required by any other method (maximum ten months).

- New Body Extracts with Antispasmodic and Tonic Effects J. S. Schwarzwann—p. 336
- New Methods of Microscopic Examination of Biologic Fluids A. W. Hochloff—p. 338

Significance of Colloid Reactions of Cerebrospinal Fluid—Fischer and Busch give attention primarily to the colloidal gold and mastic tests. In discussing the foundations of the colloid reactions, they show that the coarsely dispersed globulins usually exert precipitating action on the colloids while the action of the finely dispersed albumins is protective. The curves that develop as the result of the reciprocity between the precipitating and the protective actions can be differentiated into the left and the right curves. In the first of these

the precipitation begins in the left half of the series of test tubes (larger quantities of cerebrospinal fluid), while in the right curves it begins in the right half of the series of test tubes (highly diluted fluid). It is incorrect to talk of paralytic or syphilitic curves, for these occur not only in syphilitic conditions but also in a large number of organic disturbances of the central nervous system. Thus the significance of the colloid reactions lies not so much in their diagnostic precision as in the sensitivity with which they indicate the presence of organic disturbances of the central nervous system. Right curves, which indicate an increase in the protein with involvement of the albumins, occur almost exclusively in meningitides, in cases of blocked cerebrospinal fluid and in tumors. The left curves occur primarily in parenchymatous or in vascular disorders of the central nervous system, such as syphilis, multiple sclerosis, poliomyelitis and encephalitis. The authors list four groups of concurring signs and show what each indicates. 1 Colloid reactions of the parenchymatous type with positive syphilitic reactions and with a more or less pronounced increase in cells and protein, indicate syphilitic disease of the central nervous system. 2 Colloid reactions of the parenchymatous type, with negative syphilitic reactions, exist in various organic diseases of the central nervous system, particularly in encephalitis, multiple sclerosis and poliomyelitis. The existence of seronegative forms of syphilis, such as tabes and congenital syphilis, is, of course, possible. 3 Colloid reactions of the meningeal type: great increase in the number of cells and in the proteins, exanthochromia and fibrin curds are found in meningitides. In the cases that are of syphilitic origin the syphilitic reactions are positive. In other types of meningitis the syphilitic reactions are negative. 4 Colloid reactions of the meningeal type: absence of increase in the number of cells, great increase in the protein content, xanthochromia, fibrin curds and negative syphilitic reactions are the signs of blocked cerebrospinal fluid and indicate an obstruction in the cerebrospinal fluid spaces.

 *Influence of Contraction of Spleen on External Function of Pancreas. O. Da Rin—p. 184

Elimination of Tetra-Iodophenolphthalein in Diabetic Patients.—Pinelli made cholecystographic studies of ten patients with diabetes mellitus and diabetes insipidus. The patient on a fasting stomach received intravenous injections of 45 mg of tetra-iodophenolphthalein, dissolved in 40 cc of distilled water, for every kilogram of body weight. The author obtained in almost all cases an early opacity of the gallbladder, which may be attributed to hyperactivity of Kupffer's cells, which fix and in a short time usually spread the iodized substance, it also may be attributed to the hepatic cells which rapidly eliminate a great amount of bile containing iodine into the gallbladder, producing the normal visibility in a short time. In eight patients presenting diabetes mellitus, the gallbladder became visible rather early. Filling began from a half to one and a half hours after injection. The maximal opacity and distention of the gallbladder were observed from two to two and a half hours after injection. The gallbladder became smaller and began to lose its opacity after from three to seven hours, after seven hours a fair concentration still could be observed, even though the organ was reduced in size. From twelve to sixteen hours after injection the roentgenograms showed no filling of the gallbladder. In seven out of eight cases the gallbladder appeared normal in form and size but of an extremely intense opacity. The rate of dextrose in the blood did not increase after injection of tetra-iodophenolphthalein. In two patients presenting diabetes insipidus, the opacity of the gallbladder appeared early and no modification of the glycemic rate was observed.

Influence of Contraction of Spleen on External Function of Pancreas.—Da Rin studied the behavior of the lipolytic and amylolytic powers of pancreatic juice in normal persons before and after excitation of the splenic region with spraying of ethyl chloride and with ether packs. The author's experiments showed an increase of these properties after

excitation of the spleen. He maintains that this increase of lipolytic and diastasic powers depends on the introduction into the circulation of large amounts of acetylcholine from the spleen which in turn stimulate the external function of the pancreas through the vagal route. Before splenic stimulation the lipolytic properties show values varying from a minimum of 145 to a maximum of 305. These lipolytic values after splenic excitation present increasingly marked and constant modifications. In fact, in some subjects the lipolytic power increases to more than double the initial value. In other cases the increase is less marked but still worthy of consideration. Favorable results were obtained in the study of the amylolytic properties. In all patients there was a minimum increase of 1 and a maximum of 13.3 amylolytic units, corresponding to a production of 1 Gm dextrose per thousand. The author does not accept as proved the opinion expressed by others that the spleen takes part in the digestive process by introducing special hormones into the circulation.

 Mucocoele of Appendix. Case. C. Tarantino—p. 206

Postoperative Hyperazotemia and Hypochloremia.—Calzolari observed the variations of the urea and the chlorides of the blood in twenty patients following surgical intervention. Toward the fifth day these substances reached their maximal concentration. After this in cases with a favorable course there was a tendency to return to normal values. Hyperazotemia always evident, fluctuated between a maximum of 0.11 Gm and a maximum of 0.5 Gm. Such an increase is well tolerated by the patient. Hypochloremia always present, becomes more evident if the entire cellular amount is estimated instead of the single chlorides of the plasma. The relation between the cellular chlorides and those of the plasma gives a more exact idea of the effective lowering of the chlorides. There does not seem to be any direct correlation between hyperazotemia and hypochloremia so far as it is possible to verify the presence of the two conditions separately and at different times, yet, as a rule, they disappear simultaneously. The return to normal values of blood chlorides in cases of marked hypochloremia greatly favors the return to normal of the blood urea. The administration of sodium chloride to all patients for a few days after operation is a good prophylactic measure.

Accidental Spontaneous Rupture of Pregnant Uterus.—Margottini states that accidental spontaneous rupture must be distinguished from inevitable ruptures in etiology, localization and time of occurrence. The accidental ruptures are the result of lesions residing exclusively in the uterine wall, which may be congenital or acquired. Multiparity, scars and infections are the usual causes of the lesions. The site of these ruptures may be in any layer of the uterine musculature. The ruptures may occur during parturition (in the period of dilatation) or during the last months of pregnancy. In the author's patient rupture occurred at the beginning of labor in the scar of a previous cesarean section and the fetus passed into the peritoneal cavity. The author states that the rupture was caused by the attachment of the placenta to the area of the uterus weakened by the scar.

 Lactic Acid as Food. Amelia Azarola and J. A. Collaza—p. 283

Benign Acute Lymphocytic Meningitis.—Lopez Albo and his collaborators state that lymphocytic meningitis is not an epiphenomenon but is a disease in itself. Provisionally, the existence of an idiopathic lymphocytic meningitis caused by an

invisible virus may be admitted. The existence of a lymphocytic meningitis of reticulo-endothelial origin is possible. In the presence of an amicrobic lymphocytic meningitis with normal or slightly diminished dextrose and chloride content of the cerebrospinal fluid, the possibility of a tuberculous origin by direct action of the tubercle bacillus should be eliminated. A meningitis ending in recovery may be considered tuberculous in cases in which the diminution of dextrose and chloride in the cerebrospinal fluid was great, in patients presenting tuberculous lesions or a positive skin reaction. In all cases that clinically suggest a meningeal reaction and show a total or preponderant lymphocytic formula, it is advisable to perform a chemical, cytologic, bacteriologic and serologic analysis of the cerebrospinal fluid. The examination should be repeated during the course of the disease. Eventually blood examinations and inoculations of the cerebrospinal fluid in animals should also be made in order to reach a more precise diagnosis. The forms of serous meningitis, meningeal states, meningeal reactions, meningism, acute aseptic meningitis, and lymphocytic and sympathetic meningitis should be differentiated. Perhaps, hysterical meningitis corresponds to benign lymphocytic meningitis. The failure to detect micro-organisms in the cerebrospinal fluid in the presence of meningitis does not mean that the case is amicrobic, because it is possible for the pathogenic organisms to be killed during the first phase of their invasion of the subarachnoid space.

Follicle Persistence with Glandular Hyperplasia of Endometrium—Tietze discusses follicle persistence with glandular hyperplasia, a condition that is sometimes designated as metropathia haemorrhagica. His discussion is based on observations in 466 cases, which were treated at the clinic in Kiel in the last ten years. The author stresses the higher incidence of the disturbance at the beginning and at the end of the period of sexual function and the fact that in most cases of glandular hyperplasia disturbances in the menstruation exist before the onset of the disease. In the differential diagnosis all acyclic hemorrhages have to be considered, namely, incomplete abortion, endometritis after abortion, true endometritis, polyps, submucous myomas and carcinoma of the neck and the body of the uterus. In connection with the clinical peculiarities of glandular hyperplasia in follicle persistence the author discusses cases that developed after pregnancy and cases with short or with prolonged hemorrhages and relapses. He describes anatomic observations on the ovaries, the endometrium, the myometrium and the tubes and states that, in all but one of the cases in which a histologic control was possible large cystic, granulosa-bearing follicles were found. The result of this is a hyperplasia of the endometrium, the myometrium and the mucous membrane of the tubes. As the source of the hemorrhage, the hyperplastic endometrium was of greatest interest.

Gonorrheal Vulvovaginitis in Small Girls—Iwanow shows that in children the gonorrheal inflammation does not have the tendency to spread superficially over the mucous membranes of the vulva and vagina but rather tends to go deeper in the connective tissue layers. Above the foci of severest inflammation, the structure of the epithelium covering is generally changed. It becomes thinner and readily permeable, and thus the fluid products of inflammation and the cellular elements of the subepithelial infiltrate (together with the gonococci) come to the surface of the mucous membrane. The vaginal mucous membrane of small girls may appear entirely normal at the sites of gonorrheal inflammation. The primary

location of the gonorrheal vulvovaginitis in small girls is the vulva. As a rule, however, the inflammation exists only in spots, particularly in the recesses and folds immediately underneath the epithelium. The inflammation is severest where the secretion stagnates, that is, in the vaults, in which the gonococci can invade the tissues. In treating gonorrheal vaginitis of small children it is therefore necessary to remove the secretion by irrigation. The mucous membrane of the cervical canal always remains free from inflammation. The occurrence of gonococci in the rectal secretion does not indicate the presence of a gonorrheal inflammation.

Extrapleural Filling of Lung—Schmidt experimented with several substances consisting of a gelatin base with various fillers, such as wax, stearin, starch or cellulose. An addition of wool fat was necessary to obtain a soft consistency. He tested the various substances in animal experiments. In parallel animal experiments, the histologic changes caused by paraffin fillings were studied. The latter, in addition to good encapsulation, frequently showed complete organization, particularly in case of the smaller fillings. In a patient in whom a filling of 1,000 Gm had been introduced to effect pleural adhesions in bronchiectasis, an invasion of connective tissue into the filling could be observed. The new substances were tried in the hope that they would prove superior to paraffin because of their greater ease of preparation and use and because of their better organization. It was found that the wax-gelatin filling fulfilled these requirements, for it healed into the organism without disturbances and became firmly fixed by encapsulation and organization. Reduction of the size of the filling by resorption was never observed. Consequently the wax-gelatin filling is suitable for operations in which the filling is to remain. The wax-gelatin is not so suitable, however, if a filling is made only for the purpose of producing pleural adhesions, because the organization makes the later removal of the filling difficult. The animal experiments indicate that the wax-gelatin filling may be employed also in the plastic repair of tissue defects. The substances containing stearin, starch or cellulose proved unsuitable for fillings, because they caused irritation and disintegration.

- *Treatment of Extensive Burns of First Second and Third Degree with Cod Liver Oil W. Löhr—p. 263

Treatment of Burns with Cod Liver Oil—Löhr states that the cod liver oil treatment of burns does not influence the primary shock but is remarkably effective in controlling the secondary infection of large areas. A rapid cleansing of the wound follows its application, and epithelization is stimulated to a degree not seen in any other form of treatment. It is superior to the tannic acid method in that it can be used on the face and in such difficult regions as the buttocks, scrotum and anus. The cod liver oil was used as a salve or in combination with the cod liver oil plaster-of-paris cast. Attention is called to the fact that commercial cod liver oil is sterile. Under the influence of the oil and the rest secured by the cast, extensive and deep ulcerations in most difficult

locations heal in the surprisingly short period of from eight to fourteen days. The closed method of treatment with the cod liver oil plaster-of-paris cast is particularly applicable in second degree burns of the extremities. Secretions may be copious in the first few days and make it advisable to replace the original cast. As a rule, the cast is kept on for two weeks. Third degree burns of the extremities are treated by enfolding the extremity in sterile towels thickly covered with the cod liver oil salve. After a few days a cast may be applied, especially when contractures about the joints are feared. The author was particularly impressed with the remarkable regeneration of epithelium over large surfaces, such as the entire back.

Cultivation of *Spirochaeta Pallida*—On the basis of extensive studies, Jahnelt states that there exists no method which permits the cultivation of *Spirochaeta pallida*. He studied so-called pallida cultures prepared by other investigators and found that they were not identical with *Spirochaeta pallida* in their staining characteristics or in their biologic properties. In all respects they were identical with the saprophytic spirochetes of the human genital region.

Inhibition of "Dopa Reaction" by Vitamin C—Schroeder, after reviewing the so called dopa reaction (also called Bloch's reaction), directs attention to the presence of depots of vitamin C in organs, which either participate in the pigment metabolism or are located near pigment depots. He studied the action of ascorbic acid on epinephrine, which is chemically related to dioxyphenylalanine (so called dopa). He observed that vitamin C inhibits the oxidation of epinephrine. This inhibition of the oxidation showed itself through lack of discoloration but was demonstrated also in the blood pressure test and in the modification of the blood sugar curve of rabbits. The author thinks it probable that the stabilization of the epinephrine action observable in metabolic experiments is the result of the vitamin C content of the suprarenal cortex. In other experiments he studied the influence of pure crystallized ascorbic acid on Bloch's reaction. He found that ascorbic acid really prevents pigment formation in the tissue sections. He calls attention to a report in the English literature according to which vitamin C reduced the pigmentation of the skin in a case of Addison's disease.

- Progress in Knowledge of Sympathetic Nervous System and Its Clinical Particularly Neurosurgical Significance P Sunder Plassmann — p 432
- *Clinical Aspects of Corpus Luteum Hemorrhages H Markus — p 435

Is Iodoform Superfluous?—According to Leusden this question is answered in the affirmative by many physicians, who either have an aversion against the strong odor of the substance or have an idiosyncrasy against it. He however, has a different point of view and states that he would not do without iodoform in the treatment of surgical tuberculosis (amputations in cases of tuberculosis of bones and joints) of sanious processes and of conditions in which sanious conditions are likely to develop. He recommends iodoform also as an antiseptic following excision of contaminated wounds. He

wants iodoform kept in the therapeutic armamentarium, because the various substitutes, particularly for iodoform gauze, do not give such satisfactory results.

Corpus Luteum Hemorrhages—Markus points out that corpus luteum hemorrhages formerly were considered primarily the result of ovarian pregnancy. However, later observations revealed that the number of cases without pregnancy far exceeded those with pregnancy. In the majority of cases of ovarian hematoma, the other parts of the genitalia show pathologic changes such as myomas, retroflexion, carcinoma or adnexitis. Moreover, intra-uterine pregnancy may play a part and the so called small cystic degeneration has been considered an etiologic factor. The hemorrhage may develop without unusual cause, but in many cases a trauma (bimanual examination, overexertion in gymnastics, excessive abdominal pressure) precedes. As a rule the hemorrhages occur shortly before menstruation or at the time of the rupture of the follicle, but it may set in at any time. The hemorrhage may be slight and take the form of a retro uterine hematocoele, but a slight initial hemorrhage eventually may be repeated in a more severe form. The symptoms differ. Many cases are diagnosed as appendicitis and their true nature is recognized only in the course of laparotomy. The more profuse corpus luteum hemorrhages often present the symptomatology of those occurring in extra-uterine pregnancy. If the intra-abdominal hemorrhage is recognized the following considerations may permit the diagnosis of corpus luteum hemorrhage: (1) The amenorrhea characteristic for extra-uterine pregnancy is absent, (2) frequently there is no vaginal discharge of blood, (3) the intra-abdominal hemorrhage begins near the time of menstruation or of follicle rupture, (4) the presence of an intact hymen gives almost complete certainty. Since corpus luteum hemorrhages occur often at an early age, a virginal hymen is found in a considerable percentage of cases. Once the condition has been recognized, laparotomy should be performed immediately, but the intervention should be as conservative as possible. The ovary should not be removed unless it is absolutely necessary. The author thinks that in most cases the suturing of the bleeding cyst is sufficient. He gives the histories of two cases.

Serotherapy of Weil's Disease—Uhlenhuth and Zimmermann describe a laboratory infection with Weil's disease. In the process of inoculating guinea-pigs with the ictrogenous spirochete, some of the highly virulent material was squirted into the face of a laboratory assistant but not, as she maintained into her eyes. The face was immediately disinfected with alcohol, but Weil's disease developed in spite of this. The symptomatology was atypical, and only the demonstration of the spirochetes made the correct diagnosis possible. As soon as the spirochetes had been detected, the patient was given an intramuscular injection of convalescent serum. Because the effect of this measure was favorable, the authors recommend early serotherapy of Weil's disease by means of convalescent serum or of rabbit serum. For the laboratory personnel working with the ictrogenous spirochete they recommend immunization.

- *Seroreaction Valuable for Diagnosis of Glandular Fever H Lehndorff — p 447
- Is Suppression of Hemorrhoidal and Menstrual Hemorrhages Significant? B Aschner — p 450

Treatment of Arterial Embolism—Denk advises that, as soon as the diagnosis of arterial embolism has been established the patient should be given an intravenous injection

of one or two ampules (0.03 or 0.06) of synthetic papaverine. If after half an hour the circulation improves and the pains are lessened, the injection may be repeated two or three hours later. After that the injections are repeated after suitable intervals until the circulation has been restored, which may require from one to four days. On the second and third day the intervals between the injections may be lengthened. However, if after the first or second injection no effect is noticeable, embolectomy should be resorted to as quickly as possible. The injections of synthetic papaverine were ineffective in old cases, that is, when the first injection was made after the embolism had existed for twenty-four hours or longer, and also in patients with severe sclerotic changes in the vascular system. But even in such cases the injection treatment may be tried first, since if all preparations for an embolectomy are made there is no loss of valuable time. The author employed the injections in ten cases, in eight of them a lower extremity and in two an upper extremity was involved. In six cases the embolism could be counteracted by the injections alone. The failures were due in two cases to belated treatment and in one to severe sclerosis. The fourth failure could not be accounted for. In a supplement to his paper, the author states that the injection of synthetic papaverine may be tried even in pulmonary embolism, for not only did he find it effective in one case but he also cites another author who has recommended it.

Seroreaction for Diagnosis of Glandular Fever—Lehndorff calls attention to a peculiar reaction in the serum of patients with glandular fever. It is the 'heterophile antibody reaction,' also designated as the Hanganatzu-Deicher test, which is demonstrable by nonspecific agglutination of the corpuscles of sheep's blood. The technic of the test is simple. The serum of the patient is inactivated by exposing it for thirty minutes to a temperature of 58°C. Then a series of dilutions of serum with physiologic solution of sodium chloride is set up in the usual manner (1:4, 1:8, 1:16 and so on up to 1:4,096). To each 0.5 cc of serum dilution, 0.5 cc of a 2 per cent suspension of washed corpuscles of sheep's blood and then 1 cc of sodium chloride solution is added. The tubes are put in the incubator for two hours and then in the icebox over night. The number of cases of glandular fever tested in this manner is not large, but the outcome of the antibody reaction is so clear in all cases that its clinical value cannot be questioned. In glandular fever, infectious mononucleosis and lymphoid cell angina there is a thick clotted conglobation of the corpuscles of the sheep's blood up into the high dilutions, while in healthy persons agglutination is either entirely absent or extremely weak in the 1:4, 1:8 and in exceptional cases, the 1:16 tubes. Thus a strongly positive reaction is seen only in the various forms of glandular fever, and the test becomes a reliable diagnostic aid. In case of septic toxic symptoms and of lymphatic reaction in the blood, a strongly positive heterophile antibody reaction indicates glandular fever, infectious mononucleosis or monocytic angina and militates against leukemia.

Outis of Nurslings L. Hofmann —p. 434

Late Injuries Following Abortion—Zacherl and Richter show that the late sequelae of abortion are more severe than the immediate results. The menstruation was disturbed in approximately half the cases, amenorrhea occurring in many. A number of the women became sterile and anatomic changes

of the genitalia existed in many. Later pregnancies and deliveries showed a greater incidence of complications in women who had had an abortion than in those who had not. Frequent complications in these women were placenta praevia, weak labor pains, prolongation and disturbances of the placental delivery, fever during delivery, death of the fetus and habitual abortion. These late sequelae were especially frequent in primiparas. The fact that some of the late bad results of abortion are caused by the technic shows that it is necessary to adopt a method which is less injurious and takes the physiologic conditions into consideration. The author asks for a vigorous campaign against unnecessary abortions on the ground that they are dangerous even if done in the proper manner.

Vasomotor Neurosis of Mamilla and Mammary Carcinoma—Beck found that of 234 women with cancer of the breast more than half gave a typical description of the vasomotor neurosis of the mamilla, one third described similar symptoms, and only 15 per cent stated that they had not had symptoms of this nature. The author observed that the greatest number of women who admitted a vasomotor neurosis of the mamilla were of the light type (blond or brown hair), while those who denied this symptom were nearly all dark. He summarizes these observations as follows: 1. Vasomotor neurosis of the mamilla is most frequent in blond women and predisposes to medullary cancer. 2. Symptoms resembling the vasomotor neurosis of the mamilla are most often found in brown haired women, and in this type scirrhous of the breast is most frequent. 3. Women without vasomotor neurosis of the mamilla are mostly of the dark type and develop the comparatively rare colloid cancer in the highest percentage of cases. A comparatively high percentage of women with the vasomotor neurosis of the mamilla show neuropathic symptoms. The author shows on genealogical tables that a predisposition to cancer is hereditary and that the vasomotor neurosis of the mamilla is a hereditary factor, on the basis of which there develops in the majority of cases a carcinoma of the breast, usually of a definite anatomic type.

*Surgical Treatment of Gastroduodenal Ulcer H. von Haberer —p. 903

Surgical Treatment of Gastroduodenal Ulcer—Von Haberer has returned to the first operation of Billroth which he modified by diminishing the size of the gastric stump through ligation of the individual blood vessels in the submucosal layer. A new duodenal bulb develops some time after this operation, which, together with the anastomotic ring, insures a rhythmic emptying of the stomach. No stenosis of the anastomotic ring was ever noted. Fine catgut sutures are employed for all the layers. Comparison of large statistics, such as his own, with those of Enderlen show certain agreement in their point of view. Both practice extensive resection and regard the gastro-enterostomy as only a palliative procedure. In both clinics, excision of the ulcer was abandoned some time ago. Their incidence of recurrence amounted to about 1 per cent. In the treatment of acute perforation, Enderlen prefers a simple suture without the gastro-enterostomy, while the author's preference is for partial gastric resection. That a perforation favors the healing of an ulcer is not in accordance with his experience. The possibility of a malignant degeneration of the gastric ulcer has assumed importance in recent years. In his own experience it amounted to about 9 per cent. In the author's clinic, malignant degeneration was noted with greatest frequency on the lesser curvature. He performed a gastric resection for a large duodenal ulcer penetrating into the pancreas in a boy aged 8 years and in a girl aged 14. The symptoms in both had existed for six years. He prefers the combination of local with splanchnic anesthesia to inhalation anesthesia. While the inci-

dence of postoperative pulmonary complications is not less with the former than with the latter, the damage to the heart, the circulation and the parenchymatous organs is obviated. Among the postoperative measures the author stresses the use of the duodenal tube in cases of atonic or bleeding stomach. The tube may be left in for twenty-four hours and will serve as a means of emptying the stomach and supplying the fluids. He believes that the picture of gastroduodenal ulcer in the United States presents a milder aspect and that the cases come earlier to operation. This accounts for good results with less radical procedures than those practiced in Germany.

*Diagnosis of Trichomonads W Bender and O Hettehe—p 930

Diagnosis of Trichomonads—After trying various methods of staining, Bender and Hettehe found a method that makes it possible to detect within a short time even old cases of trichomoniasis. The basic principle of the method is the readiness with which the leukocytes and other elements of the leukorrheal discharge are stained by an aqueous suspension of brilliant cresyl blue. The trichomonads remain unstained and can be recognized by their property of reflecting strong light. There are two types of trichomonads, the flagellate form and the cystic form. The flagellate forms are about twice the size of lymphocytes, have an oval body and are highly motile. Through the influence of medicaments they gradually lose their motility and their flagella and assume a roundish, cystic and smaller form. The authors assume that the cystic form undergoes division and that this in turn explains the rapid relapse after treatment is interrupted. In order to be able to determine the therapeutic effects of various remedies, they devised a method that permits the counting of the trichomonads. Pus is thinned out with formaldehyde treated physiologic solution of sodium chloride and stained by the method described. Then the trichomonads are counted in the Thoma-Zeiss chamber. The values fluctuate between 120 and 800 in 1 cc. In cases that had undergone treatment there were rarely more than from 100 to 150 nonmotile and small trichomonads. The authors are convinced that their easy and rapid method will reveal trichomonads in many cases of leukorrhea in which otherwise they would not be detected.

Posterior Flap Approach to Talocrural Articulation in Cadaver Experiment A Lurje—p 90

First Stages of Coxa Plana—Waldenström proves by his bilateral cases that coxa plana develops in a hip joint previously normal. A case may show incipient coxa plana in the right hip joint, while the left hip joint is normal, the left hip joint may still be normal sixteen months later, and after another eighteen months typical coxa plana may be demonstrated in a previously normal joint. The clinical symptoms, a slight limp and a trifling reduction of the mobility, probably make their appearance before any evidence of the change becomes visible in the roentgenogram. The most important diagnostic indication of coxa plana in its earliest stages is the flattening of the epiphysis, which may be observed when the clinical symptoms have been present only a month. This flattening of the epiphysis is seen most clearly in the roentgenograms in lateral projection (flexion-abduction position) because

the aplation chiefly concerns the anterosuperior part. In all cases of coxa plana, the distance between the epiphysis and the bottom of the acetabulum is greater than normal from the beginning of the disease. This distance is measured best from the medial part of the epiphysis to the bottom of the socket, that is, to the lateral leg of the U-shaped figure. It increases steadily with the progression of the disease. Its cause is the flattening of the femoral head and the resulting displacement of the latter to the side and upward in the acetabulum. At first there is no change in the shape of the acetabulum. The change in the latter takes place secondarily, as an adaptation of the socket to the deformed head, and only after some time. When the head has assumed its final shape the adaptation of the socket is completed and, as a consequence, the distance from the epiphysis to the bottom of the acetabulum is again normal and the head fits into the socket.

*Contribution to Knowledge of Postoperative Changes in Blood P Windfeld—p 82

Climacteric Keratoderma—Havthausen describes post climacteric hyperkeratoses limited mainly to the palm of the hand and the sole of the foot. They appear in the earliest stages as scattered, sharply defined elements of regular, round or oval form from the size of a lentil to a pea. Hyperemia and itching are absent. When the disturbance has continued for a time it is often complicated with eczema, especially in the palm of the hand, and itching may occur. The elements become more indistinct in contour and irregular, hyperkeratotic parts with milium vesicles and deep fissures form in the middle of the palm. The disorder is frequently accompanied by adiposity, hypertension, and arthritis of the knees (Gram's triad) and is assumed to be, like these, a result of endocrine disturbances following the menopause. The eczema on the hands usually yields to treatment with ointment, but the use of thyroidin and different ovarian preparations has not in any case effected complete disappearance of the keratoses.

Postoperative Changes in Blood—In Windfeld's material of eighty-one patients with afebrile disorders, nine had fractures and seventy-two were operated on. Examinations of the blood were made to determine the cell volume, thrombocyte count, sedimentation reaction, amount of fibrinogen, serum albumin, serum viscosity, amount of calcium in plasma and serum, and time of coagulation. He says that neither marked changes nor the absence of changes in the blood factors after operation afford evidence of a supervening complication and that examinations of this kind cannot be expected to aid in the early recognition of a beginning thrombosis.

Schönlein-Henoch Disease—In the first of Schetelig's patients, a girl aged 4½ years, the disorder set in with pronounced abdominal pain, diarrhea and vomiting and was followed by repeated eruptions of purpura, subcutaneous edema, pain in muscles and extremities, and finally by a hemorrhagic nephritis. There were violent reactions against proteins and animal albumin, both on parenteral and on oral administration. The second instance, in a boy of 16 years, presented a far milder form of the disease, with typical outbreaks of purpuric patches. The third case, in a man aged 24, was characterized by a long-continued hemorrhagic nephritis. Treatment with a diet deficient in albumin and with papavarine-atropine methyl nitrate preparations gave good results.

THE FAMILY DOCTOR AND THE CHANGING ORDER

PRESIDENT'S ADDRESS

WALTER L. BIERRING, M.D.
DES MOINES, IOWA

In assuming the office of President I feel a deep sense of humility and keen appreciation of the responsibility entailed in following the distinguished teacher and surgeon who preceded me as well as the long roll of noted leaders in American medicine who have graced this high station.

I have been impressed with the wisdom of having a year of training as president-elect and the opportunity offered of gaining a closer familiarity with the administrative affairs of our great association. I wish it were possible to give a vivid portrayal of the extent and the comprehensive character of its activities.

The Board of Trustees has prepared this year a motion picture, which will serve to illustrate the magnitude of the physical plant and likewise permit a wider conception by the membership of the loyalty, integrity and scientific ideals of the administrative and editorial officers in maintaining their stewardship. Through the medium of *THE JOURNAL*, published weekly, and eight or more special monthly publications, there are brought to the members all new discoveries pertaining to the causes, diagnosis and treatment of disease throughout the world. The Association further exercises its particular educational function in making available for the general practitioner and the specialist every phase of medical progress so essential for the continuing development of the experienced physician.

By means of the Council on Medical Education and Hospitals and the various bureaus, the members are kept conversant with the advancement in methods of medical training and the different forms of licensing procedures, as well as those changes in the social order that affect the interests of the individual physician.

As members of an age-old guild, we are governed in our rules of conduct largely by tradition. Medical knowledge as we know it today is not of recent origin but rather the assembled facts of many treasured traditions, the impress of the master on disciple and student by the written or the spoken word through succeeding generations.

As history is simply the biography of the mind of man, so is the medical knowledge of our day but the sequence of epochal events each new discovery forming the basis of a new truth to follow. Again the development and growth of this knowledge has always

been intimately related to the type of medical education and practice of the art prevailing in each particular period of organized society.

While we treasure the rich heritage that runs back into the sources of the past, we have come to recognize that much of the old has passed away. A changing order is bringing new problems into the practice of medicine such as it has not encountered before. Therefore the time has come to look forward and try to read the days ahead in the light of what has happened in the past.

Since the turn of the century man's environment has changed, largely as the result of the expansion of his control over physical forces, as in the growth of speed, the elimination of time and space, and the enlargement of the dominion of man's skill and knowledge. This new environment has however not produced a new society, and in some respects the individual units of society have not kept pace with the changing world. Nevertheless the thoughts and interests of society are closely concerned with the striking changes that are taking place in the forms of medical and nursing service, particularly as to its availability and cost.

The increasing interest in matters medical on the part of modern society is the result of a long process of public education by various agencies, in which our association has taken a leading part.

Through the medium of radio broadcasting, special publications, public lectures, the efforts of various speakers' bureaus, operating through national, state and affiliated medical organizations in conjunction with various governmental agencies, interwoven with boards of education, public health services, children's bureaus, hospitals and scores of other units, there has become fixed in the public mind such things as the importance of well being, why and when to call a doctor, child health and the rearing of children, preventive medicine in its several forms, the control of tuberculosis, heart disease and cancer, as well as much sound advice as to diet, and general rules of hygiene.

As a consequence of this form of public instruction society is thinking about medicine, particularly in the field of constructive health, as it has never thought before, which has resulted in a fast enlarging body of well informed people of better discernment as to what is required in the way of medical service.

THE FAMILY DOCTOR OF THE FUTURE

A new sort of clientele is emerging for the doctor of the future that will call for all the social and intellectual adaptability at his command. In this new order of society there is a call for a different type of family doctor or general practitioner than was required a generation ago. Although of somewhat different mold, he will be the central figure in the field of medical prac-

President's address before the American Medical Association at the Eighty-Fifth Annual Session, Cleveland, June 12, 1934.

tice as in the ages past. He is the basic doctor of tomorrow and of the new order. It is for him that medical faculties will be enlarged, courses of study extended and physical equipment utilized to the highest degree. He will approach the threshold of medicine with a broad cultural training in the natural sciences and the humanities, so that he can read aright the faults of heredity and the laws of eugenics, to interpret more readily the problems underlying the biologic delinquencies which constitute the greatest burden of modern society.

For further training in the basic medical sciences and the clinical art of diagnosis and treatment of disease, this country affords ample facilities in medical schools and teaching hospitals. The future curriculum will however place special emphasis on clinical instruction in preparation for the broad field of general practice. For him diagnosis will constitute an intellectual accomplishment rather than the application of numerous instrumental aids or laboratory conclusions. The thorough preparation of the family doctor will therefore entail an added responsibility on the medical faculties of the future. Aside from his higher medical attainments, he will be a man of broad vision, calm judgment with the human touch, and a full appreciation of the needs of the individual patient.

In the general field of preventive medicine there will be ample opportunity for his art. Governmental health agencies are concerned largely with the community control of infectious diseases as they occur in smaller or larger epidemic form, but the family doctor will have his opportunity as individual health adviser, particularly in connection with the various preventive and immunizing procedures to protect the child and the adult from the different diseases of infectious nature.

A much wider field of service is encompassed in the early recognition and possible control of the organic disorders, such as the diseases of the blood, heart and blood vessels, the kidneys, the digestive tract and the nervous system.

The symptoms of fatigue, loss of weight, shortness of breath, pain with ordinary physical effort, impaired appetite, backache, moderate disturbances in kidney function, cough, dizziness and headache will have a special meaning to the family medical adviser with his knowledge of personal habits, familial tendencies and environmental conditions, and the further ability to investigate thoroughly the significance of such minor symptoms. It must be equally manifest that in any campaign for the control of cancer the family doctor will have a very important function. The intelligent advice that he will be able to give in acute or chronic conditions requiring surgical treatment, as well as faithful association with the operating surgeon in the further care of the patient, will be of inestimable service and comfort to all concerned.

The constant increase of mental disease is one of the major economic and social problems of this day. Some idea of the magnitude of the problem may be gained when it is stated that the number of new commitments to institutions for mental disease has almost paralleled the increase in matriculation in the colleges of the country. Most mental patients have a long history with symptoms appearing years before the real condition is manifest. The hope of dealing with the problem lies in early diagnosis in general practice and appropriate direction and treatment of each condition.

One of the important functions of the future family doctor will be concerned with the maintenance of health of his people, thus serving them as a faithful adviser during the state of well being as well as when they are ill. Periodic health examinations will be an important part of his practice, although the initial stage of enthusiasm for such examinations seems to have waned some in recent years. Quite recently the Massachusetts State Medical Society challenged the necessity for annual examinations, characterizing them as a luxury and maintaining that "universal investigation of recently acquired trivial signs and symptoms by the family doctor would be more profitable than the periodic health examination." We all appreciate that the individual with a backache or a headache will probably seek a medical examination more readily than when no such complaint is manifest.

The liberal qualifications prescribed for the family doctor of the new order would seem to correspond to the well trained internist or pediatrician and to a certain extent such a comparison is well applied. Emergency surgical treatment may also be a part of his function.

Although the family doctor or general practitioner will maintain a slightly different rôle from what he had in the past, he will continue to occupy the center of the medical stage and by reason of his broad medical training will be perfectly competent to take care of 85 per cent of general medical practice, besides being equally competent to know when, where and how to seek advice and aid in the other 15 per cent. He will likewise be the integrating force, the coordinator in establishing relations with the specialist in the best interest of the patient.

SPECIALISM IN THE FUTURE

The number of specialists may be somewhat more limited in the future, but they will be distinctly of a higher order. The specialist in any particular field from now on must furnish qualifications that have passed the scrutiny of his peers.

Special boards of examiners are established in the specialties of ophthalmology, otorhinolaryngology, obstetrics and gynecology, dermatology, pediatrics and radiology. A number of other specialties will probably organize similar boards in the near future. Last February a national advisory board of the medical specialties was formed, having for its purpose to coordinate and unify the qualifying methods of the constituent specialty boards. Hereafter the names of qualified specialists who have been properly certified by their respective examining board will be submitted to the Council on Medical Education and Hospitals for endorsement and publication as such in the Directory of the American Medical Association. The value of such certification for the public welfare and the profession will be generally recognized.

The family doctor as he has been portrayed, and the highly qualified specialist will be the medical pioneers of tomorrow and are destined to preserve the highest traditions of our guild. As we view with some satisfaction the outlook for the practice of medicine in the changing order, we are faced at the threshold with the same problem that is giving so much concern to the medical economists of this day. Thoughtful observers have recognized that doctors are being trained without any consideration of possible consumer requirements and beyond the limit that society can adequately support.

NEW PROBLEMS

Changing social and economic conditions will continue to influence the practice of medicine, and aside from those previously mentioned there are further factors that will have an important bearing on the medical practice of the future.

There are now no more frontiers. Country life is disappearing, and the existence of our people is changing from a rural life to essentially a city and suburban existence. The general population is not increasing as formerly, in fact there is every indication that by the year 1960 the birth rate and death rate will have reached a balance. As a result fewer children will be born and fewer will die in childhood. Furthermore a greater number of persons will live beyond former limits and succumb to those diseases incident to the aging process and the degenerative changes of later life. Certain diseases, as typhoid, malaria, smallpox and diphtheria, are much less frequent than formerly and are likely to become less so in the future. It may logically be assumed that during the next generation the family doctor or general practitioner is going to be mainly concerned with problems of nutrition and infectious diseases in the young, the metabolic disorders and hazards of industry in the adult, and the degenerative diseases peculiar to the old.

During the past year and a half the Bureau of Medical Economics of the Association has conducted a careful survey with regard to the distribution of physicians in the United States. When this is completed a more definite determination as to the actual ratio of physicians to population in different areas will be available. Nevertheless, when considered in the light of present acute problems of the practitioner and the facts concerned with the future practice of medicine one is forced to the conviction that more doctors are being turned out than society needs and can comfortably reward. In the recent State Board number of *THE JOURNAL* an editorial statement was made that, in 1933, 5,012 new members were added to the medical profession in the United States through licensure, while the losses by death for the same period were approximately 3,500. The net gain of 1,500 is about 1 per cent of the number of physicians actually practicing in the United States.

The census of 1930 shows an increase in population during the preceding decade of 6 per cent, or an annual rate of increase in population of something less than 0.6 per cent.

With the pendulum swinging toward a balanced population, it will be clearly evident that the time is coming, and not far distant when the principal function of medical service can be effectively furnished by half the number of medical graduates that we now have.

According to the report of the Commission on Medical Education, the United States has more physicians per unit of population than any other country in the world, and twice as many as the leading countries of Europe. With a total of 156,440 licensed physicians in the United States at the present time, there is one for every 780 persons. England has one doctor for 1,490 persons. France has one for 1,690, and Sweden has one for 2,890.

It is estimated that a reasonably complete medical care can be provided in this country on the basis of one physician to about 1,200 persons—that an adequate medical service for the United States could probably be provided by about 120,000 active physicians.

According to these figures there are at present a surplus of approximately 35,000 physicians.

"If the present rate of supply is continued, the number of physicians in excess of indicated needs will increase. By actuarial calculations it is estimated that by 1940 there will be in round numbers 171,700 physicians, and in 1980 about 211,800. The number of persons per physician in 1940 will be 760, in 1960 about 730, and in 1980 about 690."

It requires no special actuarial philosophy to forecast what such a state will mean to the economic welfare of the future practitioner.

It is only natural to place the responsibility with the medical schools, in that they hold in their hands the power to control the supply of physicians for the future, but the time has arrived for the American Medical Association to take the initiative and point the way. During the coming year the Association, through the Council on Medical Education and Hospitals, will institute a resurvey of the medical schools of this country. Whether the problems of this new day in medicine will be met by a limitation in the number of existing institutions or the number of students admitted cannot be foretold, but it will require real courage and tenacity to bend the educational processes to the urgent social and economic needs of the changing order. A fine piece of educational work could well be done if we were to use only one half of the seventy-odd medical schools in the United States.

It will be claimed that to close educational doors of any kind to ambitious youth is undemocratic and un-American, that, if a young man or woman wants to study medicine and can pass the necessary examinations, he or she should be free to do so. Yet, if I read the signs aright, the truly democratic process will be to take thought about the good of the whole, and less about the special satisfaction of the few. In one of the enlightened democracies of the old world, Sweden, this is being successfully accomplished. It will also be argued that in a democracy of forty-eight states the control of the number of physicians to be licensed is the prerogative of the individual state. A precedent has however been established by our neighbor to the north in the province of Alberta, where legislation was recently adopted that no more physicians will be registered in the province until the proportion has risen to 1 for 1,200 of population.

The present system opens the responsibilities of medical service not only to a larger number than can support themselves properly but to many who have not the basic qualifications for the study and practice of medicine.

The wise selection of fewer students can well be left to the educational faculties. It is now well recognized that the yardstick of basic qualifications is not confined to academic grades, for it is more important and fundamental that the prospective medical student have those attributes of personality characterized by an alert imaginative mind, physical and moral vitality, honesty, loyalty, resourcefulness and adaptability. He must be the kind of person who can deal effectively with sick lives as well as damaged organs or impaired physiology.

Much of the present unrest and anxious emotion about state and socialized medicine is the result of economic fear and uncertainty and in large part due to the social dangers that have developed as the result of an overcrowded and ill distributed body of doctors.

At a recent Medical College Centenary occasion in the state of Ohio, a leading educator and medical school administrator made this problem of an oversupply of medical graduates the theme of his address and sounded an urgent academic appeal for concerted action to meet the challenge of the changing order.

If the educational forces will respond to this clarion call in sympathetic and active cooperation with the American Medical Association, its constituent membership and the licensing bodies of each state, we shall once more have put our own house in order and a new day will dawn in American medicine. In the spirit of this enlightened sentiment we may then approach the coming day in fullest confidence that the cultured family adviser will come again to his high estate and the idealism of medical service exemplify the labors of the doctor as in the ages past.

We may likewise entertain the hope that those who follow can justly say in the words of the old Scot, 'they caught the 'gleam' an' followed it'.

Again, if we follow the lamp that appears to light the way, it will but confirm the prophetic words of the French philosopher Rene Descartes, spoken more than three hundred years ago: "If ever the human race is lifted to its highest practicable level, intellectually, morally and physically, the medical profession will perform that service."

DURATION OF IMMUNITY FOLLOWING VACCINATION AGAINST SMALLPOX

W PALMER DEARING, M D

AND

M J ROSENAU, M D

BOSTON

It is still the traditional belief that the protective effects of vaccination last about seven years. The basis of this dictum lies in the observation that immunity to smallpox wears off in some individuals, and the magic number seven has been taken as the time to revaccinate. In the earlier studies on revaccination, results were recorded as successful, "a take," or unsuccessful, "no take." In the latter case the inference was drawn that the person was immune. This does not necessarily follow.

In the light of present knowledge, the reaction on revaccination is classed as immediate, accelerated or primary, depending on the period of incubation, the height of the reaction and the course of events. The immediate reaction indicates immunity, the accelerated reaction partial immunity, and the primary reaction that immunity has worn off. Jenner knew of the reaction now called immediate and described it as occurring when variolous matter is inserted into the skin of persons who have had a prior attack of smallpox or have been vaccinated. The immediate reaction is usually so slight, however, that it was overlooked during the greater part of the nineteenth century.

In the earlier literature on this subject many revaccinations were reported as unsuccessful which, it is now known, must have been immediate reactions. The data collected before the immediate reaction was recorded therefore need revaluation.

In our experience, all individuals properly vaccinated exhibit a take. We have seen no exception. Failure

to take indicates an inactive virus, no insertion, or some other fault in technic. In other words, the individual was not really vaccinated.

The initial vaccination results in the classic primary take with the three-day incubation period, the three-day papular, the three-day vesicular and the three-day pustular stages succeeding with great regularity. The height is reached about the twelfth day, followed by crusting and leaving a typical scar. If the individual has been vaccinated before, the reaction is usually modified. The modified reactions are classified as either immediate or accelerated and indicate that the subject has retained some immunity from his previous experience. The immediate reaction indicates a high degree of immunity whereas the accelerated reaction indicates that the immunity has in part worn off. Finally, as second attacks of smallpox occur in the rare individual, so also may a subject lose his immunity to cowpox and exhibit all the manifestations of a primary take on revaccination.

We have been struck, however, by the rarity of a primary take on revaccination. If immunity lasts only from seven to ten years, there should be many primary takes after this interval. Such is not the case. In vaccinating medical students it is rare to find a primary take for teaching purposes, even though previous vaccination was done as much as twenty years before. In short, observations suggest that in the great majority of cases immunity to vaccinia lasts a great deal longer than has been commonly thought.

In examining this point, we have studied the records of the students in the classes in preventive medicine in the Harvard Medical School and in epidemiology in the Harvard School of Public Health. As a class exercise, the students vaccinate each other under supervision with the regular stock vaccine in capillary tubes, prepared by the Antitoxin and Vaccine Laboratory of the State Department of Public Health of Massachusetts. Each student makes a written report of the course of his reaction and of his previous vaccination history.

During the last three years, in observation of more than 400 vaccinations, we have seen only five primary takes, two of these were in students who had had smallpox in childhood but had never been vaccinated. Of the remaining three, one reported four prior unsuccessful vaccinations, one had been vaccinated over twenty years previously, and the third had been vaccinated only two years before. The last is an example of the very occasional individual who seems to maintain little or no immunity to cowpox, indicating that he might have had two attacks of smallpox if exposed.

In addition to the data collected during the past three years, we have records submitted at the time by the classes of 1916, 1919, 1920 and 1924. From the individual reports of these seven classes, we have tabulated the data on the types of reaction which occurred, with relation to the time that elapsed since the last previous vaccination.

The character of the eruption and the time of reaching its height were used as criteria, because they were more definite than the period of incubation. Reactions were classed as immediate if they remained papular throughout the course, or if they reached their height within seventy-two hours. The takes were classed as accelerated if a vesicle developed and if they reached their height between the fourth and ninth days. Reactions were classed as primary if they reached their height the tenth day or later. There was little tendency

for overlapping of accelerated and primary reactions, in all but one or two cases, the height was reached on the eighth day or earlier, or else on the eleventh or twelfth day. There was slightly more tendency for merging between accelerated and immediate reactions, but again the great majority fell definitely into one or the other category.

It is of considerable interest that, even in medical students on the lookout for reactions, the small papule of the immediate reaction was often unnoticed until attention was called to it by itching. Many reactions were so slight that they were overlooked completely, and the student reported "no take" until the instructor pointed out the characteristic papule. Small wonder that the reaction was overlooked for almost a hundred years!

In tabulating the data, we have grouped the cases according to whether the last previous vaccination was less than five, from five to nine, from ten to nineteen, or twenty or more years ago. The reactions in individuals who had had only one prior vaccination are recorded in table 1. The persons who had had two or more vaccinations prior to the class exercise are tabulated in table 2. The two groups were separated thus to discover whether the number of previous vaccinations had any effect on the duration and degree of immunity following the last vaccination. In the two tables the data from each of the seven student classes are recorded separately to show both the variations that occur and the essential consistency of the observations from year to year. Table 3 summarizes the facts.

Of the 557 revaccinations, only eleven, or 2 per cent, gave primary takes. Of these primary reactions, ten appeared on the second vaccination (table 1) and only one after two or more previous vaccinations (table 2).

This distribution suggests that there is less chance of a primary take if the subject had been previously vaccinated twice or more. Seven of the ten primaries on second vaccination, however, occurred in 1920. There were five among twenty-one vaccinations in the ten to nineteen years group and two among thirteen cases twenty or more years after first vaccination. This indicates an abnormal distribution in 1920, since no other such figure appears in our series (table 1). Only one primary take appeared less than five years after initial vaccination (table 1) and the rest after ten or more years had elapsed.

With regard to the distribution of immediate and accelerated reactions, the two groups (tables 1 and 2) are entirely consistent within the limits of chance variation. Also, the percentage of immediate reactions decreases from above 90 within five years to under 70 after twenty years. Conversely, the percentage of accelerated reactions increases from below 5 to about 25 in the same time interval between vaccinations. We again call attention to the essential consistency of the figures, where the discrepancies appear large, as in table 1, class of 1924, ten to nineteen years group, the figures are small—nine cases in this instance.

Examination of the data on immediate and accelerated reactions ten years or more after prior vaccination

shows an interesting change during the period of time covered by our data (comment in tables 1 and 2). In the earlier years 1916, 1919, 1920 and 1924 the percentage of immediate reactions ten years or more after prior vaccination is definitely lower than in the later period from 1931 to 1933. Conversely, there are more accelerated reactions. For example, the earlier period in table 1, ten to nineteen years group, shows seventy-two vaccinations with only 53 per cent immediate

whereas the later years show fifty-two vaccinations with 88 per cent immediate. This confirms an impression that accelerated reactions were more frequently seen then than now. This may very well have resulted from the change in technic during this time. Extensive insertions, $1\frac{1}{2}$ inches (3.8 cm) or more in length, were formerly insisted on in the belief that large takes gave better immunity. It is now known, however, that small insertions, not over one-eighth inch

(0.32 cm) long, give satisfactory immunity with the minimum of inconvenience to the subject.

In the course of these studies we encountered nine students with a history of smallpox, attested in each case by the telltale pockmarks. These are recorded separately because the students had never been vaccinated (table 4). Only one gave an immediate reaction, and four of them gave primary takes. This confirms a similar observation made by one of us¹ at Eagle Pass in 1895, that individuals vaccinated shortly after recovery from smallpox often gave primary takes.

It is of interest for control purposes to add that in each year the potency of the virus was indicated by the occurrence of at least one primary take in the class. These do not all appear in the tables, because some individuals had never been successfully vaccinated before. This control is desirable because of the fact that "immediate" reactions can be elicited with heated or otherwise inactivated virus.²

SUMMARY AND CONCLUSIONS

The duration of immunity to smallpox as indicated by the results of vaccination was studied in 557 medical students who had previously been vaccinated and in nine who had never been vaccinated but who had had smallpox. Of 337 students vaccinated ten years or less after previous vaccination, only one gave a primary take, fifteen, or 4.7 per cent, gave accelerated takes, and 321, or 95 per cent, an immediate reaction. Of

the 168 students vaccinated from ten to nineteen years before, only six, or 4 per cent, gave primary takes, fifty, or 29 per cent, gave accelerated takes, and 112, or 67 per cent, immediate reactions. After twenty years, of fifty-two reactions, thirty-five, or 67 per cent, were immediate, thirteen, or 25 per cent, were accelerated, and 8 per cent gave primary takes.

It is welcome news that immunity conferred by a single vaccination usually lasts longer than the traditional seven to ten years, and that the benefits conferred extend for twenty years or more in most individuals. Revaccination reinforces protection and, as our records here presented show, is usually a mild experience. Certainly nothing in these facts should alter the procedure of always vaccinating when exposed or in danger of exposure to smallpox.

The situation with reference to smallpox is interesting. Vaccination of nine individuals with a history of smallpox who had never been vaccinated gave four primary takes, four accelerated takes and only one immediate reaction. Experience teaches that smallpox usually protects against itself, second attacks are rare. It does not, however, protect so well against cowpox, as our data show. On the other hand, experience in every epidemic of smallpox in which vaccinated individuals were exposed has demonstrated the powerful specific protection afforded by vaccination.

BERIBERI FOLLOWING DRASTIC VOLUNTARY DIETARY RESTRICTION

DAVID RIESMAN, M.D., Sc.D.

PHILADELPHIA

AND

HAROLD S. DAVIDSON, M.D.

ATLANTIC CITY, N. J.

Beriberi is looked on as a tropical or exotic disease but the conditions that are alleged to give rise to it may conceivably occur elsewhere. A few instances have been encountered in badly run prisons and insane asylums, but sporadic cases are on the whole sufficiently rare, in this locality at least, to justify us in placing two on record.

Beriberi is a vitamin B deficiency disease characterized by cardiovascular changes, edema and polyneuritis. Historically it is a very ancient malady. It appears in Chinese writings of the Sun and Tang dynasties at the beginning of the seventh century. A description dating back to 610 A. D. is clear enough to indicate that a moist and a dry form of the disease were then recognized just as is the case today. Under the name of kakke the malady makes its appearance in Japanese literature in the ninth century. The first indubitable descriptions are, however, not found before the seventeenth century. An early account by a European was written by Malcolmson in 1835. About the middle of the nineteenth century the publications multiplied rapidly, largely by reason of work by Europeans studying the problem in Asia both on the mainland and in Japan and on the islands of the Straits and in the Philippines. The disease was a great scourge in the armies during the Sino-Japanese War (1894-1895), occurring in 17.56 per cent of the troops, and in the Russo-Japanese War (1904-1905), in 16 per cent. One fourth of all hospitalized soldiers had the disease.

Read before the Section in General Medicine of the College of Physicians Feb. 26, 1934.

¹ Rosenau, M. J. Report of the Surgeon General U. S. Pub. Health Service 1895.
² Andervont, H. B. and Rosenau, M. J. J. Immunol. 18: 51 (Jan.) 1930.

Early writers believed that beriberi was caused by an infective agent, but in 1895 Eijkman¹ made experiments that not only resulted in clearing up the cause of beriberi but threw a flood of light on the whole subject of deficiency diseases. He fed hens nothing but polished rice and produced polyneuritis, exhaustion and death, while a diet of rice and barley or of only half polished rice prevented the disease. Between 1900 and 1910 proof was definitely brought forth that beriberi was a nutritional disease. Fraser and Stanton in 1910-1911 showed that beriberi could be prevented among the natives of the Malay peninsula by a diet of parboiled rice and that it could be prevented under the same condition even when the men also received polished rice. Similar experiments were made by Chamberlain, Vedder and their associates in the Philippine Islands. A little later Takaki² succeeded in conquering beriberi in the Japanese navy by a change of ration.

The accessory food factor that is responsible for beriberi is the soluble antineuritic or B vitamin, which in nature is usually associated with a closely related substance called the antipellagra vitamin (B_2 or G). These water-soluble vitamins are contained in vegetables, fruits, milk, yeast, kidney, liver, brain and whole grain. Recent studies seem to indicate the possible existence of seven components in the B complex.³

Clinically, beriberi presents itself in two fairly distinct forms: one in which polyneuritis predominates, the other in which edema is the outstanding feature. In the former a differential diagnosis between beriberi and polyneuritis from other causes is sometimes required. The senior author many years ago called attention to the similarity between alcoholic multiple neuritis and the deficiency diseases. It is well known that steady drinkers in whom alcoholic multiple neuritis later develops rarely partake of an adequate amount or of a proper kind of food.

Edematous cases of beriberi can be distinguished by the fact that pressure on the calf muscles produces severe pain; it has also been noticed that beriberi patients have difficulty in rising from a squatting position. If the diagnosis proves doubtful, the therapeutic test may decide. Under the specific therapy, the administration of foods that contain vitamin B, beriberi patients promptly recover.

Nutritional or war edema is allied to beriberi in that it is also a deficiency disease. It results from living on a diet containing too little protein and an excess of fluid and salt. Polyneuritis is not common in war edema. Some cases of war edema are probably due to an acute glomerulonephritis.

Patients with beriberi, as in our own first case, usually complain of dyspepsia. They seldom have spontaneous pain but they lose all appetite, acquire a loathing for food and have a sense of fullness in the stomach which in the more severe cases may pass into nausea and vomiting. The first characteristic symptom as a rule seems to be weakness in the legs, later a moderate edema, paralysis of the legs and general nervous disturbances such as irritability, headache and dizziness are added. Changes in the skin in the form of hemorrhagic exudates often appear. Fever is usually absent unless complications ensue. Palpitation on exertion and shortness of breath are present and become more

marked as the disease progresses. The heart is usually enlarged, especially toward the right, but the edema is out of all proportion to the clinical evidence of cardiac changes during life. With respect to the changes in the heart, the recent studies of Wenckebach⁴ are interesting. He found the right heart extraordinarily overfilled, the muscle being stretched and flattened out. These pathologic changes throw light on the sudden deaths that are so common in beriberi. The vascular symptoms often closely resemble those of aortic insufficiency.

E. W. Our first patient, a white man, aged 76, married, retired from business, complained of greatly swollen, painful legs, and digestive disturbances. His father, mother, two brothers and three sisters had all died of old age. The patient had typhoid in infancy. When he was 23 he had a "heat stroke", at that time he was given so many different kinds of medicine that ever since he has had stomach trouble for which he has seen many specialists in this and foreign countries. Gradually he eliminated one article of food after another, since nearly everything gave him a feeling of distress in the stomach, with belching of large amounts of gas.

About a year and a half before admission he became so ill that he discontinued all foods, except milk, of which he took about 3 quarts a day. As this caused diarrhea, he was forced to cut down the amount by one half. He grew progressively weaker and in August 1933 his legs began to swell. The swelling became more and more pronounced and eventually involved the face and hands. He was dizzy and extremely irritable and so weak that he had to be lifted from his bed to a chair. The greatly swollen legs were intensely painful and he screamed when they were touched. Eventually he became utterly helpless and could no longer leave the bed but lay with his swollen legs drawn up and supported by pillows under the knees. With difficulty he was induced to take a little milk but would take nothing else in the way of food. Somewhat later pruritus and became very annoying, and he at last consented to see a physician. A skin specialist treated him without any relief. It was at this time that he was first seen by one of us (D.) and a week later by the other (R.). There were large ecchymotic spots on the legs and buttocks. The heart was enlarged to the right, the hands, face and legs were edematous, the calf muscles were extremely tender to touch. The man was visibly emaciated, extremely pale, mentally confused and very uncooperative. A diagnosis of beriberi was made. Only the persuasion of both of us finally broke the man's resistance against going to the hospital.

The blood count on admission showed less than 7.5 Gm of hemoglobin, 2,150,000 red blood cells, 8,800 white blood cells with 82 per cent polymorphonuclears and 18 per cent small lymphocytes with a marked shift to the left. The urine was concentrated, the color of dark straw, with a specific gravity of 1.017 acid, with no albumin or casts and from 25 to 30 leukocytes per low power field.

Two blood transfusions of 250 cc each on succeeding days were given. Because of the patient's unwillingness to cooperate and to take food, a Jutte tube was introduced through the nostril into the stomach and through it large quantities of vitamin B extract, orange juice, beef juice, egg, tomato juice and cod liver oil were administered for four days. The first day his intake was 134 ounces and the output 39 ounces. Large doses of iron and ammonium citrate were also given through the tube. On the fourth day he removed the tube himself and said he would eat whatever we gave him if he was permitted to go home. He ate pureed vegetables, raw liver pulp, cooked fruit and fruit juices and took the iron without any distress. He was allowed to go home. The blood count on discharge, October 18, showed hemoglobin, 8.9 Gm, red blood cells, 2,840,000, white blood cells, 3,630, polymorphonuclears, 61 per cent, and small lymphocytes, 39 per cent with a marked shift to the left.

At home he continued to eat ravenously. A general diet was ordered: the vitamin B extract and iron and ammonium

citrate being continued. The swelling subsided within two weeks and he was then allowed to get out of bed. Though he was still very weak, the pain in the calves of the legs had almost entirely disappeared and the cecymotic spots were fading. He had no more indigestion. One month later, November 7, his blood count showed hemoglobin, 95 Gm, or 61 per cent, red blood cells, 3,500,000, white blood cells, 4,300, polymorphonuclears, 56 per cent, small lymphocytes, 43 per cent and eosinophils 10 per cent, with a marked shift to the left. He now walks outdoors unaided, is in a cheerful frame of mind and is interested in everything, for the first time in two years. He eats with relish all varieties of food without the slightest discomfort, he sleeps well and feels better than he has in years.

About a year ago Brauchle⁵ reported an interesting case which is almost a replica of the foregoing. The patient, Dr. Brauchle's own mother, aged 60, began to have pain in the left hip. After about a year other symptoms were added, such as fatigue and tension in the muscles of the legs. These complaints were at first attributed to the menopause but treatment of every sort not only was of no avail but seemed to intensify the trouble. The woman had been largely a vegetarian all her life. After a year, fever and edema appeared, the patient's weight increased from 144 to 160 pounds (65.3 to 72.6 Kg). Eventually the muscles became so weak that motion was virtually impossible and the only parts that could be moved were the mouth and eyes. One consultant attributed the symptoms to myositis, another attributed them to periarteritis nodosa but remarked casually that there was some resemblance to beriberi. It is interesting that the patient's mother had died at the age of 65 with practically identical symptoms. When she was almost moribund Dr. Birch-Benner was called in and declared at once that the disease was the wet form of beriberi. He placed the patient on a diet of raw fruit, "mush," nuts and raw vegetables, bread, milk and cooked vegetables were totally forbidden. Under this treatment the edema rapidly disappeared. Her weight dropped from 160 to 120 pounds (72.6 to 54.4 Kg), motion returned in the muscles and at the end of three years, the raw fruit being continued, the patient was able to walk any distance and to make long journeys. Dr. Brauchle and all who had seen the patient declared that her recovery was a miracle. In our case the recovery was no less striking.

An unusually interesting case is reported from the Philadelphia General Hospital by Kepler.⁶

A Negro woman, aged 28, had always been in good health. In August 1918 she had a miscarriage followed by severe vaginal bleeding. A friend recommended raw starch as a cure. Acting on this advice and later influenced by a superstition among Negroes that raw starch has cosmetic value and tends to make the skin white, she gradually ate more and more. At the end of two years this habit had increased to such an extent that she was consuming from 1 to 2 pounds daily of one of the box brands of gloss starch. Her husband had only one of his daily meals at home, and rather than cook for herself she obtained most of her nourishment from the starch. The cooked meal at night consisted of the usual staple articles of diet found on a workman's table. Under this regimen she lost her appetite and as a result she practically subsisted on laundry starch, which, so far as its vitamin content is concerned, is certainly the equivalent of decorticated rice. The hold that this habit had obtained on her can be realized from the fact that on several occasions after admission to the hospital she asked the nurses to smuggle starch to her. At the end of a little less than three years she began to have symp-

toms of polyneuritis, with a trifling edema of the buttocks. The heart was enlarged to the right and to the left and, despite the fact that there was no aortic diastolic murmur, the vascular signs were those of pronounced aortic insufficiency. As the patient also had nephritis, the primary treatment was directed toward that disease. After about ten days a diagnosis of beriberi was made and autolyzed yeast was given. A marked improvement followed. The urine became normal, various heart murmurs that had been present gradually vanished, and the pulsation of the peripheral arteries disappeared and the heart became normal in size.

A case of beriberi is reported by Swineford.⁷

A woman, aged 47, single, a native of Virginia, had a severe attack of typhoid and since then had never been entirely free from indigestion. To combat the abdominal pains she gradually reduced her diet to toast, soup, an occasional egg, corn meal, oatmeal and a rare helping of fish or chicken. She practically eliminated fruits, fresh milk, meat, peas, beets, potatoes and other vegetables from her diet. Gradually signs of polyneuritis developed, the legs became drawn up and the muscles of the calves and thigh exceedingly tender, even the bones were painful on light tapping. Alcohol could be ruled out as a cause of the symptoms. Under a high vitamin B diet the patient improved but did not fully recover.

Farnell and Yacovlev⁸ call attention to the difficulty of distinguishing at times between pellagra and beriberi.

Wohl⁹ reports a beriberi-like state in a diabetic woman, aged 32, whose diet had been improperly balanced. In considering cases of this type the thought comes to mind that perhaps the neuritis of diabetes has in it a deficiency factor.

A case of self-imposed avitaminosis partaking of the character both of scurvy and of beriberi has been reported by Bullowa.¹⁰ A man, aged 55, Irish, a hotel porter in New York, had "taken a dislike" for meat and had lived for four and a half months on tea and bread. The result was a symptom complex suggesting both the lack of the antiscorbutic and the antiberiberi vitamins.

One of us (R.) has for several years been of the belief that some of the cardiac "breaks" seen in the poor patients entering the Philadelphia General Hospital since the depression are in part due to food privation and can be corrected only by proper nutrition. It is important to inquire in much greater detail than is the usual custom into the dietetic habits of patients. One may then perhaps learn that many common diseases, infectious and others, arise largely on the basis of faulty practices in eating.

Our second case was diagnosed as beriberi by one of us (R.) through consultation with the patient's physician, who described the results of his examinations.

A young woman, much overweight, in an effort to reduce her avoirdupois had adopted a meager and monotonous diet. After a few weeks she became short of breath and had palpitation and edema of the legs. These symptoms induced the belief among her medical attendants that she was suffering from heart disease. She had no rheumatic history, never had been ill with anything that could have given her heart disease and, prior to her voluntary dietary restriction, had been athletic and in the best of health. To my mind there was in this patient no primary cardiac trouble. The symptoms were those of a deficiency disease, in other words, it was the picture of the wet form of beriberi. Under a sensible dietetic regimen and that alone, the young woman made a prompt recovery.

As long as fashion decrees the sylphlike figure, sporadic cases of beriberi are likely to occur. They may show only an incomplete picture of the disease but if the true cause of the symptoms is not recognized, the trouble may be ascribed to primary myocardial disease with inevitable failure of treatment.

The period of vitamin shortage that an individual may safely endure is variable, being influenced by several factors.¹¹ It is quite possible, although by no means proved, that the edema of wet beriberi is due to a shortage of protein. This would suggest a multiple deficiency in this type of the disease.

Of the sources of vitamin B for clinical use, yeast and wheat germ are the best. Liver, kidney and brain are richer than muscle in vitamin B. The whole grains, because of their content of germ, contain appreciable amounts in contrast to the highly milled products such as white flour and degerminated corn meal. Among the fruits and vegetables, tomatoes, raw cabbage, fresh spinach and legumes have been found to contain more than orange or lemon juice, onions, cauliflower or lettuce. The vitamin in the egg is located in the yolk. Milk, although a good source of the pellagra preventive substance, does not contain a large amount of vitamin B.

A MILK AND BANANA DIET FOR THE TREATMENT OF OBESITY

GEORGE A. HARROP, M.D.

BALTIMORE

During the course of certain studies on the comparative value of various carbohydrate foods, particularly cooked and uncooked fruits and vegetables, in the diet of patients with diabetes, it was observed that a diet of bananas and milk furnished a simple and effective method for weight reduction. The regimen has since been used by a considerable number of individuals suffering from simple obesity, and it is thought desirable to detail the method and the results obtained.

For the patient who is willing to make reasonable sacrifices to reduce excessive weight, the advantages of a simple, easily measured diet are quite obvious, provided it is well balanced from a nutritional standpoint and sufficiently palatable. Weight reduction usually involves the breaking of a habit that is firmly entrenched. Such a habit some persons find may be easily broken by a gradual process of "tapering off," as is involved in the usual curtailment of starches, sweets and fats, but many others find this very difficult. Among these, particularly, are those who are obliged to work with food, such as housewives, who prepare the family meals. For such persons, and it is believed that they constitute a large proportion of the total who seek relief, a strict regimen, resolutely adhered to over a definite period, furnishes the most practical method of attaining the desired end.

A most important requirement in a reducing diet is that it give a sense of satisfaction or "fulness." This is not always met merely by the use of bulk. What is called the satiety value of a diet is said to be furnished largely by foods high in fat content. The explanation given is that either alone or in combination with other foods they stimulate gastric secretion and prolong gastric digestion. The consequent slow emptying of the

stomach produces the satisfactory prolonged sense of fullness.¹ Be that as it may, the fact that the banana is a "filling" food is a matter of common observation. Notwithstanding this property, however, the banana has a nearly negligible fat content. Indeed, very few foods possess a satiety value for the average person comparable to that of the banana unless they contain considerable proportions of fats with the resulting high caloric value. On the other hand, the high carbohydrate content of the banana effectively counteracts any tendency to ketosis during periods of marked caloric restriction.

The use of milk for the reducing diet seems to date from Moritz,² who adapted it from the regimen of Karell.³ Used as the sole article of food, it is simple and cheap, but to many it is monotonous and flat. The use of skimmed milk in reducing diets has also been common for many years. Its caloric value is about one-half that of whole milk, while the essential nutritive constituents, with the exception of the butter fat and its vitamins, are retained.

A combination of milk and bananas is simple and palatable. The portions to be taken are readily measured, no preparation is necessary and they are universally available. Such a diet for reducing weight is very inexpensive when compared to the foods commonly used in reducing regimens, particularly the meats and salads. As a useful and practical foundation for a reducing diet, (1) the combination may be utilized for one or two meals, with moderate restriction of the third, or (2) it may be taken as the entire diet for from ten to fourteen days, then exchanged for a more varied regimen for a similar period in which the weight loss is maintained but not increased. The use of alternate periods of starvation and restricted diet was used by Folin and Denis⁴ and was considered "perfectly safe, harmless and effective."

1. When used as a continuous diet, one or two large ripe bananas may be used with one glass (250 cc.) of whole milk for both breakfast and lunch. This is followed by a restricted evening meal, consisting of clear soup, a slice of lean meat (or fish or fowl), two or three portions of 5 per cent vegetables, a slice of bread and butter, and a portion of uncooked fruit. Such a diet will contain from 1,000 to 1,200 calories and may be continued for an indefinite period with satisfactory results.

2. The second method involves the use of bananas and skimmed milk alone for periods of from ten days to two weeks, then alternating with a more liberal regimen.

BANANA DIET REGIMEN WITH ALTERNATE PERIODS OF RESTRICTED AND LESS RESTRICTED DIET

Period of Strict Diet—The strict diet consists of six large bananas and 1,000 cc. of skimmed milk, to be eaten in three or more meals, spaced according to the personal food habits of the individual. The food value of this diet is given in the accompanying table.

Only fully ripened bananas, i. e., fruit with yellow skin flecked with brown, should be used. It is easy to have such bananas available each day by purchasing in advance, when necessary, green tipped or firm yellow

fruit and allowing it to ripen fully at room temperature. The skimmed milk is obtained by pouring off the top fourth of a quart bottle, which contains the cream, and using the remainder. Buttermilk made from skimmed milk may be used in place of the plain skimmed milk if desired. A salad of one fourth of a medium sized head of lettuce, or of an equal quantity of cabbage, with a small amount of mayonnaise dressing made with liquid petrolatum,¹ is a useful and valuable addition at one meal during the period of strict diet.

Food Value of Skimmed Milk and Banana Diet

	Carbohydrate	Protein	Fat	Calories
6 large bananas	132	8	1	569
1 000 cc of skimmed milk or four ordinary glasses	50	36	3	371
Total food value	182	44	4	940

This diet is followed for from ten days to two weeks and usually produces a weight loss of from 4 to 9 pounds (1,814 to 4,082 Gm) in persons who are moderately active and carry on their usual living routine. Reduction of the diet to four bananas daily is well tolerated by many and the results are more striking. Weakness and severe physical discomfort, however, must be avoided. Fluids without food value, including tea or coffee, but without cream or sugar, are permitted freely. Salt is avoided to discourage retention of body fluid. An adequate fluid intake must be insisted on, preferably never less than 1.5 liters, or six large glasses daily, in addition to the milk. Such fluids without food value or salt do not increase the weight and are an important aid in guarding against constipation. On the banana diet the stools are much less bulky than on the usual mixed diet. If constipation occurs, it may be counteracted by the use of liquid petrolatum, but the use of saline purgatives is to be deprecated.

Period of Less Restricted Diet—At the end of from ten to fourteen days on the strict diet, alterations may be made as follows:

1 Substitution of one or two eggs, boiled, steamed or poached, salted, with one-fourth square of butter for one or two bananas, as the case may be. If the first period of strict diet is too rigorous, one egg, with one-fourth square of butter, may replace one banana from the outset. This entails larger salt intake but makes the regimen better tolerated for some persons.

2 Use of from one to four average servings of green vegetables, containing 5 per cent carbohydrate or less. One square of butter melted may be poured over these vegetables at the table, but no butter or fat of any sort should be used in the cooking.

For most persons these vegetables are most satisfying in both flavor and bulk when placed in boiling water to which a pinch of salt is added. They should be removed just as soon as tender but before the fresh flavor is lost by prolonged heating.¹ The melted butter should be added at the table directly to the food portion, where it can be seen and enjoyed. Any condiments without food value, including vinegar, may be added as desired. Provided the butter is sharply restricted to the amount mentioned, the quantity of the vegetable taken may usually be unrestricted. It is advisable to use one or more helpings of these vegetables occasionally uncooked.

3 Addition of one small portion of any lean meat, fish or poultry, except pork. No thickened gravy is to be used.

No fat-containing foods, except the portions of butter expressly mentioned, and no foods containing sugar or starch in any form are to be used.

The regimen as outlined is to be followed alternately from ten to fourteen days of the strict banana and skimmed milk diet is followed by two weeks of the less restricted diet, as just given. During the less restricted period, care is taken to avoid regaining weight, but no further loss is desirable. At the end of the less restricted period of two weeks the strict diet is again resumed for two weeks, and so on until the desired loss is made.

A small group of persons have either a distaste or an idiosyncrasy for bananas. Their use is not practicable in such cases.

The limit to which reduction may be safely undertaken is frequently placed at 1 or 2 pounds (453.6 or 907 Gm) per week, or from 5 to 10 pounds (2,268 to 4,536 Gm) per month. Each patient, however, presents an individual problem. Rapid reduction is well tolerated by some, others must reduce more slowly. The state of well being, mental and physical, is a most important guide. Some hunger and weakness during the first three or four days of the milk and banana regimen are common and must not be regarded too seriously. Such symptoms usually disappear at the end of a week and are replaced by a feeling of well being. Certain persons complain of drowsiness early in the evening on a reducing diet, adjustment of the menu to allow a light lunch late in the evening may be helpful to such persons.

Weight loss in excess of 2 or 3 pounds (907 or 1,306 Gm) a week, except when the diet is very markedly curtailed, represents an excessive loss of water. The patient should be warned that the larger losses of weight which may take place during the early days of dieting are due to loss of water and will not continue. Three fourths of the weight of the soft tissues is composed of water, and it is often stored temporarily in place of fat. The effect of this temporary storage must be explained to patients in order to dispel the common impression that it is possible to hold or even gain weight on greatly reduced diets. Low salt intake is useful in facilitating more rapid equilibrium. If the storage and excretion of body water is chiefly regulated by the storage and excretion of sodium, as it appears to be, a low salt intake should discourage retention of both sodium and water. Such appears to be the case on a diet of bananas and milk. The comparatively low sodium intake on this diet produces in most persons a more even loss of weight than is often found in diets with such a high carbohydrate moiety.

Although the nitrogen intake is much lower in this diet than in the diets described in current publications,⁶ it is noteworthy that the nitrogen balance has been attained in six cases studied when on the strict diet at the end of one week, and of two weeks. In four it was not, but the nitrogen loss in no case exceeded 2 Gm a day after the end of the tenth day. The weight losses in this entire group ranged between 4 and 11 pounds (1,814 and 4,990 Gm) for the two weeks. Rubner.⁷

observed that uncooked fruits and vegetables can reduce the protein metabolism to low levels, almost to the wear and tear quota

"It is a valuable piece of information to know that one may diet an obese patient on a food (milk) containing little protein and two-thirds the body's energy requirement, without danger of protein loss"⁸

SUMMARY

A diet having as its basis bananas and milk is proposed for the treatment of overweight, on the grounds of simplicity, low cost, ready availability, palatability, high satiety value, low salt content and demonstrated effectiveness in securing the desired aim

CONVALESCENT SCARLET FEVER SERUM AND COMMERCIAL ANTITOXIN

A COMPARISON OF THEIR PROTECTIVE VALUES

PAUL S RHOADS, M.D.

AND

BENJAMIN M GASUL, M.D.

CHICAGO

Since its introduction by Weissbecker¹ in 1897, scarlet fever convalescent serum has proved useful in the treatment of scarlet fever. The results obtained have been variable, probably because there has been much variation in the size of the doses used. Among sixteen authors² reporting results since 1912, the therapeutic dose varied from 10 to 240 cc. At present the trend is toward smaller doses.

Reports of protection of contacts by means of convalescent serum are meager. Degkwitz³ treated 509 scarlet fever contacts, using 5 or 6 cc for children up to 8 years of age and 10 cc for those from 9 to 14 years of age. All but three escaped the disease.

Neff⁴ used convalescent serum in doses of from 15 to 30 cc for prophylaxis in twenty-five contacts, with no failures. Meader⁵ of the Detroit health department reports that, of 450 contacts who were given 7.5 cc each of pooled convalescent serum from donors who had had scarlet fever within a year or a little earlier, 29 per cent contracted the disease. In similar groups that did not receive convalescent serum, 12.8 per cent of the subjects came down with scarlet fever. He concludes that about 85 per cent of those passively immunized were protected against scarlet fever.

The figures cited may be misleading because no data regarding susceptibility of those receiving convalescent serum are given. Also it is not stated whether they harbored hemolytic streptococci at the time the serum was given. Since in an average group only from 40 to 50 per cent are susceptible and only a small percentage may be carriers of hemolytic streptococci, to conclude that all who did not develop scarlet fever were protected by convalescent serum is erroneous.

Some in each group were undoubtedly immune before the convalescent serum was administered, and others were not infected with scarlet fever streptococci.

In their first publication on the skin test for susceptibility to scarlet fever, the Dicks⁶ showed that a considerable quantity of convalescent serum was required to render Dick positive persons Dick negative. In one case it was necessary to give 10 cc of convalescent serum on three different occasions, at intervals of three, seven and nine days, respectively, to render a person Dick negative. This quantitative element in the use of convalescent serum has been neglected. One example from our own experience is, perhaps, sufficient, although similar cases have been observed.

A woman, aged 33, a laboratory technician, was secured to work in the Cook County Contagious Hospital. Before going on duty she was given a Dick test, which was strongly positive. In order to give her some protection until such time as she could be actively immunized, she was given 7.5 cc of pooled scarlet fever convalescent serum, the dose being used for prophylaxis at that time by the Michael Reese Hospital Serum Center. On the same day another Dick test was performed, and the following day the test was again strongly positive. Two days later she came down with a typical attack of scarlet fever. After the rash was well developed, there was blanching at the site of the convalescent serum injection.

That prophylactic doses of regular commercial antitoxin have been uniformly successful in affording complete passive immunity under similar circumstances has also been repeatedly demonstrated.

A nurse was sent to the Contagious Disease Hospital with scarlet fever, Jan 10, 1933. Two days later her roommate, who had not been Dick tested or immunized at the Cook County Hospital, was found to have a slight sore throat, slight nausea and malaise. Her temperature was 99.2 F, the pharynx was slightly inflamed, but there was no rash. She was isolated, nose and throat cultures were made on blood agar, and a Dick test was performed. The next day the throat culture was positive for hemolytic streptococci and the Dick test was positive. A prophylactic dose (100,000 neutralizing units) of scarlet fever antitoxin, prepared by a state health department, was given intramuscularly, and at the same time another Dick test was made. Scarlet fever did not develop. When the patient was observed the next day, the Dick test was negative.

In an experience of eight years in controlling scarlet fever outbreaks in schools, orphanages and homes, one of us (P S R) has used scarlet fever antitoxin repeatedly in this way, but only when the Dick test and throat cultures were positive and there were clinical signs, such as fever, nausea or an inflamed throat, indicating that scarlet fever was imminent. Antitoxin has always prevented the development of scarlet fever.

We felt that it would be of value to determine the titer of several lots of convalescent serum in order that a more accurate comparison with commercial antitoxin might be made. At the time that this study was undertaken, pooled human convalescent scarlet fever serum was being used freely in the Contagious Disease Hospital and was being distributed throughout Chicago by the Michael Reese Serum Center. Its average titer was not known, but it was distributed in doses of from 7.5 to 10 cc for prophylaxis and from 20 to 60 cc for therapy.

Through the courtesy of Dr S A Levinson of the Michael Reese Serum Center, we obtained twelve different lots of pooled scarlet fever convalescent serum for study. Precisely the same method was used for titration as has been in use by one of us for several

⁶ Dick G F and Dick Gladys H. *A Skin Test for Susceptibility to Scarlet Fever*. *J A M A* 82 265 (Jan 26) 1924.

years in testing commercial antitoxins for the Scarlet Fever Committee.

Dilutions were made as follows:

1 A toxin control prepared by adding 5 cc of physiologic solution of sodium chloride to 5 cc of a solution of toxin ten times as strong as standard skin test solution, so that 0.1 cc (the amount injected) contained five skin doses.

2 A toxin-antitoxin mixture. Five cubic centimeters of the toxin dilution containing ten times the standard skin test strength was added to 5 cc of a known dilution of the conva-

After the discovery, by preliminary Dick tests, of a number of Dick positive individuals, all three dilutions were injected into the skin in amounts of 0.1 cc each after one and a half to two hours' incubation of the mixtures at 37°C. The tests were observed and recorded in millimeters, with some indication of the degree of pinkness and swelling, at twenty-four and forty-eight hours.

A typical titration record follows. If the toxin was neutralized for forty-eight hours in at least four of six

lescent serum to be tested. The preliminary dilution of serum was usually 1:5. One-tenth cubic centimeter of the mixture contained five skin test doses of toxin and an unknown amount of antitoxin. In a mixture thus prepared, if the serum was found to have neutralized the toxin a titer of at least 500 neutralizing units per cubic centimeter was assumed. (Each

satisfactory tests, the serum was considered acceptable in the dilution used. No persons whose toxin controls did not average 20 mm or over in both diameters were considered suitable subjects for the tests. If a positive reaction was obtained with the serum control, the test was, of course, disregarded.

Table 2 gives the results of twelve convalescent and three normal pooled adult serums tested. The average titer for the convalescent serum was about 500 neutralizing units per cubic centimeter, and, for the normal adult serum, less than 250 neutralizing units per cubic centimeter. All commercial scarlet fever antitoxins are tested in exactly the manner outlined here by one of us (P. S. R.) before they are distributed. No commercial antitoxin is allowed on the market unless it contains 15,000 or more neutralizing units per cubic centimeter. Thus, to introduce the accepted prophylactic dose of scarlet fever antitoxin (100,000 neutralizing units), one would have to give 200 cc of convalescent serum, or 7 cc of the weakest commercial antitoxin.

To obtain further evidence, Dick positive persons were given convalescent scarlet fever serum and Dick tests were performed the same day and subsequent days to observe at what speed passive immunization was accomplished. Another group was given commercial antitoxin in prophylactic doses and tested in the same way.

Table 3 shows that convalescent serum had no uniform effect on Dick tests performed the same day and subsequent days. In the majority of cases the Dick test was still positive the next day and for several days

thereafter In some cases, no effect whatever was noted

On the other hand, the Dick test was always completely negative the day after the injection of a prophylactic dose of antitoxin (table 4)

In our experience, the ordinary commercial preparation of scarlet fever antitoxin (100,000 neutralizing units for prophylaxis) has always afforded complete passive protection against scarlet fever in susceptible persons, if given before the onset of the disease

The results shown in this table demonstrate that 100 000 neutralizing units of antitoxin which is the required prophylactic dose for commercial products in the United States rendered the susceptible individuals immune within twenty four hours

SUMMARY

1 Cases have been observed in which the usual dose of scarlet fever convalescent serum administered to susceptible individuals failed to afford passive protection against scarlet fever

2 Using the same method as is used in titrating commercial antitoxins, we found that twelve lots of pooled convalescent serum had a potency of from less than 250 neutralizing units (a unit is the amount of serum required to neutralize one skin test dose of toxin) to 1,000 neutralizing units per cubic centimeter. The average potency was 500 neutralizing units per cubic centimeter

Commercial antitoxins are required to have a potency of not less than 15,000 neutralizing units per cubic centimeter. Thus, to obtain as many neutralizing units as are present in commercial antitoxins, at least thirty times as much convalescent serum is required

3 Twenty persons known to be susceptible to scarlet fever were given 10 or 20 cc of pooled scarlet fever convalescent serum and Dick tested, usually the same day and for a few days thereafter. Only three became immediately Dick negative. Two of these had very faint original tests. A large proportion had not become Dick negative several days later. One whose test remained unchanged three days after administration of convalescent serum at once became immune after a prophylactic dose of commercial scarlet fever antitoxin

COMMENT

At a time when convalescent scarlet fever serum is being so widely used it is pertinent again to call attention to the fact that there is a quantitative element in scarlet fever therapy that should not be neglected

Scarlet fever antitoxin has proved to be distinctly useful in preventing complications, in shortening the

febrile period, and in reducing the mortality rate, also in passively protecting scarlet fever contacts

Convalescent scarlet fever serum is useful if given in adequate amount and, in addition, has the advantage of not containing horse serum. That convalescent serum is very rarely given in adequate dosage is apparent from this study.

Unless an unusually potent convalescent serum is available, patients will receive more immune bodies from the therapeutic dose of scarlet fever antitoxin (300,000 neutralizing units) than from convalescent scarlet fever serum given in the dosage at present usually used. The benefit obtained varies directly with the speed with which the antitoxin is given.

While this communication does not concern itself with relative costs, it is worth mention that if convalescent serum is distributed through a serum center which must maintain personnel and equipment it inevitably costs much more per antitoxic unit than commercial antitoxin.

Gordon⁸ has advocated immunotransfusion for severe septic scarlet fever, claiming for it a distinct superiority to scarlet fever antitoxin. He says "With immunotransfusion the amount of protective substance is from five to ten times greater than is ordinarily accomplished by the injection of serum and, furthermore, is introduced into the blood stream directly rather than indirectly, as by the intramuscular route." Immunotransfusion is undoubtedly a useful procedure. However, in the light of the data given here Gordon's statement seems open to question.

THE CONGENITALLY SHORT ESOPHAGUS

LOUIS H. CLERF, M.D.
AND
WILLIS F. MANGES, M.D.
PHILADELPHIA

Atresia of the esophagus with an esophagotracheal fistula has long been considered the most common congenital anomaly of this structure. The fatal termination of all these cases and the opportunities afforded for the study of the malformations at autopsy has resulted in a more general knowledge and comprehensive literature of atresia than is available on congenital stenosis. Being compatible with life, congenital stenosis may not produce symptoms until solid food is eaten, in some cases symptoms of obstruction may not occur until adult life has been reached. Esophagoscopists are generally agreed that congenital stenosis is more common than their personal records or the reports in the literature would indicate. It is probable that a number of these are not differentiated from acquired stenosis, that others are treated by bouginage without a preliminary diagnostic esophagoscopy, and that an equally large number go through life with the knowledge that they cannot swallow normally but get on satisfactorily with careful selection and proper mastication of foods. A careful study of these groups would undoubtedly reveal many cases of congenital deformity. This was confirmed in certain of our cases.

In 1931, Findlay and Kelly¹ described an anomaly that was characterized by congenital shortening of the esophagus and by the presence of a portion of stomach in the thoracic cavity with stenosis at the junction of the esophagus and thoracic stomach. A detailed report of nine cases was presented. Similar cases had been previously recognized but these were confused with an associated diaphragmatic hernia of the stomach. By esophagoscopy it was found that the dilated food passageway between the point of stenosis and the diaphragm was lined by gastric mucosa. This was corroborated by histologic examination of tissue removed at esophagoscopy.

Coincident with the receipt of Findlay and Kelly's¹ report we observed identical changes in a patient admitted for removal of a bolus of meat from the esophagus. Similar studies carried out in several cases of esophageal ulceration with stenosis, previously diagnosed as peptic ulcer of the esophagus, indicated that these, too, presented a congenitally short esophagus and a thoracic stomach. Continued interest in this anomaly has led to the discovery of fourteen cases since 1931.

The scarcity of reports of these cases in the literature should not indicate that the condition is rare. With the exception of a report by us,³ all data pertaining to this anomaly have appeared in British medical literature. On the basis of our discovery of fourteen cases within four years, this condition would appear to be relatively common. Cases are probably overlooked because of the lack of a proper technic in the roentgen study and failure, on the part of the esophagoscopist, to investigate carefully the food passageways distal to the stenosis or to note the distance between the upper teeth and the point of transition of esophageal into stomach mucosa. Two of our cases had previously been diagnosed as acquired stricture, four were considered peptic ulcer of the esophagus. Ulceration was present, and, occurring at a point proximal to the level of the diaphragm, it was assumed to originate in the esophagus. The stenosis, considered as cicatricial in origin, was explained as resulting from the healing ulcer. The food passageway distal to the ulceration was not examined esophagoscopically. Consequently no opinion regarding its character was expressed.

AGE AND SEX

The series of cases reported by Findlay and Kelly¹ consisted of nine children—seven boys and two girls. Their ages varied from 4 weeks to 9 years and 10 months. Monkhouse and Montgomery⁴ reported a group of seven cases. All these were adults. Our group, consisting of nine females and five males, included one girl and three boys varying from 6½ to 9½ years, eight women from 28 to 64 years of age, and two men, aged 21 and 32 respectively. Two children were brother and sister.

SYMPTOMS

No classic symptom group has been suggested. One can divide the cases into two groups. In one, the out-

standing symptoms are dysphagia and regurgitation with disturbances in nutrition and growth. These were present in three children and two adults. In seven of Findlay and Kelly's¹ cases, regurgitation was present from birth, disturbances in nutrition and growth were observed in all. In the other group, distress, particularly after eating, was noted in addition to dysphagia with lodgment of food and regurgitation. These were

Fig 1—Short esophagus in a woman who while eating meat twenty four hours previously to examination had a portion lodge in the esophagus. In A the arrows point to a small quantity of barium that was retained in the esophagus proximal to the bolus of food. Examination was difficult because of constant retching and inability to retain the barium mixture in the esophagus. The obstruction caused by the food was practically complete. In B after the bolus of food was removed esophagoscopically roentgen examination showed a portion of stomach in the thoracic cavity with an esophagus too short to reach to the level of the diaphragm. Note the width of the opening through the diaphragm.

observed in one child and six women. Certain cases are symptom free until dietetic indiscretions result in the lodgment of food or the development of pathologic lesions direct attention to the esophagus. This was observed in the case of a man whose first symptom referable to the esophagus consisted of temporary lodgment of a portion of apple in the lower part of the esophagus six months before coming under our observation. No further disturbances were noted until three months later, when dysphagia for solid foods developed. The roentgenograms indicated that there was present an organic stenosis. At esophagoscopy there was found a congenitally short esophagus with a thoracic stomach, and an indurated area with ulceration. Tissue removed was reported by Dr B L Crawford as adenocarcinoma. This was subsequently corroborated.

Dysphagia—Careful investigation will often reveal that dysphagia was present since birth or more commonly, since solid food was added to the dietary. This was observed in eight cases. In five, difficulty in swallowing was present for "many years" to twenty years. Several found it necessary to take large quantities of fluid when eating to aid in swallowing. Regurgitation was commonly observed and usually occurred during mealtime. Lodgment of food was of frequent occurrence. Seven of the patients were referred to the Jefferson Hospital Bronchoscopic Clinic because of aphagia resulting from lodgment of food (fig 1).

Weight Loss—This was particularly noticeable in the children all of whom were underweight and poorly developed. In the case of a child aged 8 years, gastrostomy was performed because of extreme emaciation and marked dysphagia. A diagnosis of cicatricial

stenosis was made and the true nature of the condition was not discovered until esophagoscopy was done. The adults were generally well nourished, one weighing 250 pounds (113.4 Kg).

Distress—Symptoms varying from "indigestion" and flatulence to severe epigastric pain were present in seven adults and one child. These occurred very shortly after taking food. Severe pain was a prominent symptom in four. It was commonly referred to the epigastrium and behind the lower half of the sternum, in two it was also referred to the back. In three cases acid foods produced severe distress. Alkalis, notably sodium bicarbonate, gave prompt relief and were frequently employed by seven of the patients.

It was interesting to note that two patients experienced severe pain on assuming a dorsally recumbent posture, in fact, they slept only in a semi-sitting position. On further questioning it was found that relief was also secured by lying on the right side. Esophagoscopy in these cases revealed a large area of superficial ulceration at the gastro-esophageal junction. The pain was unquestionably due to contact of gastric juice with the area of ulceration. In the absence of a normal hiatus the gastric contents would gravitate upward to the ulcerated area when the patient assumed a recumbent posture. Alkalis gave immediate relief, but this was usually brief. The characteristic pain could be induced by touching the ulceration with a swab of silver nitrate solution, a topical application used in the esophagoscopic treatment. Preliminary cocaineization of the ulcerated area gave complete relief.

ROENTGEN EXAMINATION

The essential points in the roentgen diagnosis of congenital shortening of the esophagus are: First, a portion of the cardiac end of the stomach must be

Fig 2—This shows the rugae of the stomach at the level of the wide diaphragmatic opening also where the esophagus joins the stomach. There is marked dilatation of the esophagus above the esophagogastric junction. There was remarkably little esophagoscopic evidence of narrowing at the junction of esophagus and stomach.

shown to stay above the level of the diaphragm. Second, the esophagus must be shown to be too short to reach as low as the level of the diaphragm.

As to the first point, the only characteristic sign is the presence of multiple longitudinal rugae markings in that portion of the tube through and just above the diaphragm (fig 2). When this point is established,

the change of posture will not cause that portion of the stomach above the diaphragm to go either lower or higher, and there will be no variation in relations on repeated studies

As to the second point, when it is seen that a portion of the stomach is above the diaphragm it is necessary to visualize the entire length of the esophagus above the narrowing at the junction of the esophagus and stomach and show by

Fig 3—A woman aged 53 had dysphagia for twenty years. Food frequently lodged in the esophagus for brief periods. There was no history of swallowing a caustic or other injury. This case was however considered one of cicatricial stenosis until the substenotic food passageway was explored. The rugae of the stomach through a large opening in the diaphragm and the expanded portion of the stomach above the diaphragm shadow are clearly demonstrated. The upper esophagus is greatly dilated. The constricted portion is 7 cm in length.

views at different angles and positions that the esophagus is not tortuous or angulated but that it is a nearly straight tube and that the narrowed portion could not possibly reach the diaphragm (fig 1 B). If it is to be viewed at all in the light of a diaphragmatic hernia or hernia of the stomach through the diaphragm, the term "congenital fixed" or "congenital irreducible" should qualify the term "hernia". There are other contributory signs the most important of which is that the portion of the stomach above the diaphragm is larger than the esophagus and will show its true diameter or capacity only when that portion below the diaphragm is well filled (fig 2). This can be best accomplished when the patient is in the right oblique prone posture,⁵ previously described, in which position the hiatus is on a higher level than the upper end of the esophagus, and gravity tends to keep the barium mixture in the cardiac end of the stomach. In one of the cases we did not succeed in getting diagnostic evidence until the patient was placed in this posture. The right oblique prone posture is not practical for children too young or too uncooperative to carry out the act of drinking through a tube. In such cases the recumbent posture is essential and at times there is some advantage in tilting the table so that the upper end of the esophagus is at a lower level than the lower end. The only objection to this posture in adults is that the roentgenoscopic view and the roentgenograms are less clear because of the total thickness and density of the median line structures, particularly the thoracic vertebrae and the heart. When a lumen wider than the normal esophagus above the level of the hiatus has been demonstrated and there is no evidence of obstruction, either organic or spasmodic, at the diaphragm, the evidence is strongly contributory.

Roentgenographically, all our cases have shown some degree of narrowing where the esophagus joins the stomach. This appearance of narrowing does not differ greatly from that seen in strictures following injury, except that in the vast majority of instances the narrowing due to cicatricial tissue formation following injury is much more marked when it is first seen, the portion of the esophagus below the stricture is not dilated, the history is that the difficulty in swallowing has been progressive following an accident, and there is apt to be more or less emaciation (fig 3), while in the congenitally short cases the difficulty in swallowing a large bolus of solid food has always been present. The narrowing at times causes so little inconvenience that the diagnosis is overlooked entirely or is only by chance brought to light in adult life. On the other hand, the lumen has been rather small in a few cases. In two, the condition was brought to light only after complete obstruction by a bolus of food. The narrowing has been rather uniform as to location, at about the level of the seventh to the ninth dorsal vertebra.

As reported by Findlay and Kelly,¹ we found no collection of air or gas in the stomach either above or below the diaphragm. In none did we find any appreciable evidence of delay of the barium mixture at the diaphragm level, and in all of them the opening in the diaphragm was appreciably larger than normal.

As mentioned previously two of our group were of one family, brother and sister, but two other sisters and three brothers showed no abnormality.

In all our cases it was evident that the esophagus proximal to its junction with the thoracic portion of stomach was not long enough to reach the diaphragm in any posture or any state of filling with any consistency of barium mixture. A few of them showed evidence of dilatation proximal to the narrowing. Roentgenoscopic views in anteroposterior and lateral projections with the patient both standing and lying down have shown an entire absence of tortuosity of the esophagus.

Fig 4—A schematic illustration indicating the impressions gained from esophagoscopy in cicatricial stenosis and in two of the more common forms of narrowing observed in the congenitally short esophagus. In cicatricial stricture (A) the lumen is commonly eccentric with some distortion. In the congenital form of stenosis the lumen is concentrically placed and may consist of a weblike narrowing (B) or it may present a funnel like appearance of variable length (C).

CHANGES SEEN AT ESOPHAGOSCOPY

There were commonly found moderate evidences of chronic esophagitis and some dilatation of the thoracic esophagus. In three cases the suprastenotic dilatation was marked. In all the cases but one there was found a maximum point of narrowing of the esophageal lumen, which was approximately opposite the fourth rib or fourth interspace along the left border of the sternum. The stenotic lumen varied in size from one admitting a 9 mm standard esophagoscope to one that was not more than 4 mm in diameter. Resistance offered to the tip of the esophagoscope suggested an

acquired stricture. The lumen was practically always concentrically placed and lacked the distorted appearances commonly noted in cicatricial stenosis (fig 4A). The general appearances, however, were not unlike those noted in acquired strictures, although there was lacking the customary evidence of scarring of the esophageal wall. The absence of visible scarring could be readily explained by the masking effects of chronic inflammatory changes.

Fig 5—Glandular mucosa gastric type that was removed from the food passageway above the level of the diaphragm as shown in figure 6. The surface of the tissue is covered by columnar epithelial cells which are continuous with the underlying gland structure. (Histologic study by Dr B L Crawford slightly reduced from a photomicrograph with a magnification of 100 diameters.)

In two cases the stenosis was weblike, in a third the narrowing was abrupt, the lumen being about 4 mm in diameter (fig 4B). In nine cases the narrowing was funnel-like in appearance, varying from 2 to 7 cm in length (fig 4C). In one there appeared several points of narrowing within several centimeters, suggesting multiple strictures. In the remaining case there was no demonstrable point of narrowing at the esophago-gastric junction.

The appearances of the stenosed lumen, which do not resemble the normal hiatus esophageus and the resistance offered to the tip of the esophagoscope should clearly indicate that the narrowing is not of spincteric or of pinchcock origin. No opinion can be given concerning the histologic components. The resistance to dilation should indicate that it contains considerable connective tissue elements. The only available data on the histologic study of a congenitally short esophagus is reported by Jacob, Tweedie and Negus⁶ who recorded the changes observed in the case of a child aged 1 year and 7 months which came to autopsy. They found the narrowing of the esophagus beginning a short distance below the bifurcation of the trachea. It extended for a distance of 2 cm. Below this the food passage opened again and presented appearances of stomach mucosa. The lumen of the narrowed portion showed a superficially ulcerated surface. Histologic examination of the esophagus above

the stenosis exhibited a fairly normal esophageal wall with thickening of the epithelial layer and muscularis mucosae. A study of the walls below the stenosis exhibited stomach mucosa. It was difficult to identify the wall of the stricture, as the epithelium was ulcerated and no surviving fragments could be found for identification. Marked inflammatory changes were present in the submucosa and muscularis coat.

Ulceration varying from a small area at the point of stenosis to extensive changes involving the funnel-like narrowing and entire zone of stenosis was observed in eight cases. The ulceration appeared superficial, the areas were covered by a thin grayish exudate and sharply demarcated by a narrow inflammatory zone. Granulations, when present, were commonly flat. In the four cases in which severe epigastric pain associated with taking of food was complained of, the ulceration was extensive.

Immediately on traversing the stenosis, the esophagoscope entered into what appeared to be stomach, although anatomically the tip of the tube remained proximal to the level of the diaphragm. This fact might be readily overlooked unless accurate routine comparative measurements were made. Failure to traverse the normal hiatus before the stomach is entered should be suggestive of a congenital anomaly unless the stenosis involves the hiatal level of the esophagus. In no case was it possible esophagoscopically to observe a narrowing in the stomach which would correspond to the level of the diaphragm, normally the hiatal level. From an esophagoscopic standpoint one gained the impression that as soon as the stenosis was passed one entered the stomach. The patient with a gastrostomy fistula was examined by retrograde gastroscopy several times to determine this point. Through the retrograde gastroscope one could not differentiate between the appearance in this case and that in the normal except that the esophagogastric junction offered resistance to the gastroscope and could not be traversed, in addition, this point was found at a higher level than is normal.

Fig 6—Roentgenogram made in the lateral plane with the esophagoscope in situ. The tip of the tube is below the esophago-gastric junction and is in contact with the stomach wall. Tissue removed from this level proved to be normal gastric mucosa. Note that the tip of the esophagoscope and the point of tissue removal are well above the level of the diaphragm the dome of which is barely visible. The case examined in this study is shown in figure 3.

In nine of the cases, tests were made with litmus paper after the stenosis was passed to ascertain the reaction of the fluids.

It was invariably acid. This in itself is of little importance for it is a known fact that regurgitation of gastric content is not uncommon when an esophagos-

⁶ Jacob F H, Tweedie A and Negus V E. Congenital Shortening of the Esophagus. *J Laryngol & Otol* 48: 486 (July) 1933.

copy is performed on a conscious patient. To corroborate the esophagoscopic opinion that gastric mucosa was observed at a point above the level of the diaphragm, specimens of tissue were removed in eight cases. In all these histologic examination indicated the presence of normal or ulcerated gastric mucosa (fig 5). For accurate localization of the anatomic site from which mucosa was removed for biopsy, esophagoscopy was performed on a double plane roentgenoscopic table. The position of the tip of the esophagoscope at the point where the tissue was removed was recorded roentgenographically in the lateral view (fig 6).

The esophagoscopist, unaided by an accurate report from the roentgenologist regarding the condition of the food passage immediately beyond the stenosis, is often confronted with the question whether these are cases of acquired stenosis. If the point of stenosis cannot be traversed esophagoscopically, no opinion can be given regarding the presence or absence of a congenital anomaly. A negative history of injury to the esophagus cannot be accepted as conclusive evidence that a stenotic lesion is congenital, since caustics may be swallowed during the first few years of life and the accident not remembered. If the stenosis can be passed esophagoscopically, inspection of the substenotic food passageway, anatomic localization of the level of the stenosis and the presence or absence of the normal hiatal pinchcock will afford adequate evidence. The roentgenographic evidences and the esophagoscopic observations should be conclusive.

TREATMENT

The chief problems to be considered are those of providing an adequate food supply and the relief of pain. Practically all the adults observed were well nourished. Dietetic indiscretions and hasty eating were usually responsible for disturbances in swallowing. The children, however, were undernourished and poorly developed.

In the cases of web stenosis, prompt improvement in swallowing was observed following esophagoscopic dilation, since the web offered little resistance to the bougie and the tip of the esophagoscope. Satisfactory results were secured in the nonulcerated cases by proper selection of food, thorough mastication and occasional esophagoscopic dilation.

Patients with ulceration at the junction of the esophagus and thoracic stomach presented a difficult problem in treatment. Pain was the outstanding symptom. Various combinations of alkalis and bismuth subnitrate afforded temporary relief. Topical applications of silver nitrate, 10 per cent, to the ulcer seemed to be helpful. Dietetic treatment along the lines indicated in gastric ulcer is recommended. In certain of these, esophagoscopic dilation afforded relief. In one case dilation of the stenosis was followed by complete relief of pain, although ulceration persisted.

SUMMARY

Among fourteen cases of congenital shortening of the esophagus with stenosis and the presence of a portion of stomach in the thoracic cavity there were four children and ten adults. Two children, brother and sister, are of one family. Two groups of symptoms were noted, one consisting of those resulting from esophageal obstruction and malnutrition, in the other, symptoms due to ulceration were prominent, although there was some mechanical obstruction. The roentgenographic and esophagoscopic changes were those of narrowing of the lumen at the esophagogastric junc-

tion, a point above the normal hiatal level with a portion of stomach above the diaphragm. In several, superficial ulceration of the mucosa was observed at the level of the stenosis. In eight cases mucosa was removed from the food passage above the diaphragm level for histologic examination. This proved to be gastric mucosa.

MENINGOCOCCEMIA

REPORT OF TWO CASES WITH RECOVERY

ARTHUR B. RICHTER, MD

BOSTON

Meningococcemia, unaccompanied by meningitis or with meningitis occurring as a late complication, has been reported infrequently in the American literature. Cases reported in the foreign journals outnumber those in America in the proportion of six to one. Four cases have been diagnosed at the Peter Bent Brigham Hospital. The first one was reported in 1924 by Dock,¹ and the second by Marlow² in 1929. My purpose in this paper is to report two additional cases. A repetition of the description of the disease, which has been so comprehensively presented in numerous papers, especially those of Chaler, Giraud and Morel,³ Bloedorn,⁴ Dock,¹ Jacono⁵ and Binns and Fothergill,⁶ seems no longer desirable in a communication of this kind.

REPORT OF CASES

CASE 1—E. H., a white woman, aged 31, single, referred to the hospital, March 9, 1930, complained of intermittent chills, fever and skin eruptions of nine weeks' duration. A diagnosis of meningococcic septicemia had been made during the fifth week, but the administration of polyvalent antimeningococcus serum over a period of four weeks had been without beneficial effects.

The family and past histories were irrelevant. While at work and in apparently good health, the patient had had a shaking chill followed by a profuse sweat. For the following ten days she complained of weakness and migratory joint pains but continued at work. From the eleventh day until admission there was a daily rise in temperature to 104 or 105 F., usually following a chill. The rise in temperature was never sustained more than eight hours. Between the bouts of fever the patient felt fairly well. There were no abnormal physical manifestations until the intermittent appearance of a rash, first observed during the sixth week and occurring thereafter during the febrile periods. The eruption consisted of crops of deep red maculopapules and purpuric spots varying from 2 mm to 1 cm in diameter. These lesions appeared in greatest numbers on the lower extremities, but occasionally on the arms, trunk and face. The white blood cells averaged 14,000 per cubic millimeter during the afebrile periods. Three blood cultures taken during the fourth week were positive and produced a gram-negative diplococcus with the cultural characteristics of the meningococcus. The organism was agglutinated by Massachusetts and New York State polyvalent antimeningococcus serum in a dilution of 1 to 100. A brief outline of

7 I am indebted to Dr. J. M. Salles of New Bedford, Mass., for his permission to report this case. Dr. Salles was responsible for the care of the patient during the greater part of her illness.

serum therapy before admission was as follows 40 cc of Massachusetts State polyvalent antimeningococcus serum intravenously on the thirty-sixth day, with a severe reaction during the injection, from the thirty-sixth to the fifty-sixth day, 190 cc of Lilly's concentrated polyvalent antimeningococcus serum and 848 cc of Massachusetts serum subcutaneously in from 10 to 45 cc doses, on the fifty-seventh day 51 cc of New York State serum intravenously in seven doses, on the fifty-eighth day 16 cc of a special lot of serum made at the Massachusetts State laboratory, subcutaneously in divided doses, followed by 90 cc of the same kind of serum intravenously in doses of from 5 to 10 cc during the next eight days.

Though there had been no appreciable effect on the temperature, an afebrile period of twenty-four hours the longest observed, had occurred three days prior to admission. A few hours before entry the patient suddenly developed headache and pain in the back and neck. It was feared that meningitis had developed, and the patient was sent to the hospital.

On admission the patient was well developed but slightly undernourished and fairly alert and cooperative. Except for a definite tachycardia, a soft precordial systolic murmur, and small fading, red-brown macular areas on the trunk, thighs and legs the physical examination was not remarkable. The temperature was 102 F. Examination of the blood showed hemoglobin (Tallqvist), 75 per cent, red blood cells, 4,800,000, and white blood cells, 11,300 per cubic millimeter, differential polymorphonuclear leukocytes, 55 per cent, lymphocytes, 26 per cent, mononuclears, 13 per cent, eosinophils, 5 per cent, and basophils, 1 per cent. The platelets appeared normal but the red blood cells were slightly hypochromic. A blood culture on enriched mediums was sterile. Lumbar puncture was not performed. Massachusetts State polyvalent antimeningococcus serum was given intravenously as follows 10 cc shortly after admission followed by slight pain in the lumbosacral region and flushing of the face, two doses of 15 and 20 cc during the next twenty-four hours, 5 cc on the second hospital day, 15 cc on the third day, 5 cc on the fifth day, and 8 cc on the seventh day. The patient did not develop signs of meningitis or serum sickness. The temperature gradually receded to normal by the second day, and, except for an occasional rise to 99.5 F during the next five days, remained at a normal level. The patient was allowed up on the thirteenth day and she has remained well since her discharge from the hospital on the twenty-second day.

CASE 2—H. F., a girl, aged 17 years, admitted to the hospital, Aug. 29, 1933, complained of sore throat, painful joints and skin lesions.

The family history was unimportant and previous hygiene was good. At the age of 16 months the patient had acute poliomyelitis with residual paralysis of the left lower extremity. At the age of 9 years a tendon transplant operation was done. For several years she had worn a brace. In early childhood she had uncomplicated whooping cough, measles, mumps, chickenpox, and frequent spontaneous epistaxis. Menstruation began at 14 years and continued regularly with slight dysmenorrhea for three years. For one year prior to admission there had been metrorrhagia and recurring attacks of pain in the right side of the lower part of the abdomen. There was no history of venereal infection. The first attacks of tonsillitis occurred at 14 years with frequently recurring attacks usually associated with a cold. Five weeks before entry there developed a blister on the left heel with slight infection, but it was completely well before the onset of her presenting illness.

One week before admission a cold and sore throat with cervical adenitis developed. This condition had partially subsided when, in the evening, twenty-four hours before entry, there was a slight chill followed by fever and a profuse sweat. All the joints seemed to be stiff. The following morning in addition to malaise, headache, sore throat and stiffness of the joints numerous small, discrete maculopapular lesions were noted in the skin of the upper extremities. Some of these areas were painful.

The patient was well developed and nourished and appeared acutely ill. There were numerous red maculopapular lesions varying from 5 to 20 mm in diameter on the arms and dorsum

of both forearms. Some of these lesions were slightly nodular and did not fade on pressure. There were four petechiae, each approximately 2 mm in diameter in which, over the course of the next twenty-four hours, gray centers rapidly developed, as shown in the accompanying illustrations. The petechiae were located over the right olecranon process, on the dorsum of the interphalangeal joint of the right thumb, on the ulnar side of the base of the right little finger, and on the dorsum of the left ring finger. These four lesions were considered to be definitely embolic in origin and were painful. Skin lesions were found only on the upper extremities, and the maculopapular lesions disappeared within twenty-four hours of admission without residual discoloration. No petechiae were seen in the conjunctivae, mucous membrane of the mouth, or under the nails. Smears of the petechia on the right thumb showed numerous pus cells but no organisms, and cultures on enriched mediums remained sterile. No new skin lesions developed. The four petechiae healed in five days with slight bluish discoloration.

Fig. 1—On the dorsolateral surface of the left ring finger, a dark red petechia developed a gray center forming a pustule similar to that on the right thumb.

Examination also showed swelling and tenderness of the left index finger, and pain on flexion of the fingers of the right hand and on movement of the right wrist and left shoulder. The tonsils were large and acutely injected, but there was no exudate on the tonsils or posterior pharyngeal wall. The anterior cervical lymph nodes were enlarged and tender. The lungs were clear. The heart was normal except for an increased rate and a faint systolic murmur heard best at the left sternal margin in the fourth interspace. The spleen was not felt, nor was the area of splenic dullness increased. Pressure deep in the right lower abdominal quadrant caused slight pain. On bimanual pelvic examination there was tenderness in the right adnexal region, and a small mass regarded as the tube and ovary was palpated. The cervix was poorly visualized but there was a large amount of mucopurulent discharge from the vagina. Smears were negative for typical intracellular gram-negative diplococci, and culture of the pus grew only staphylococci. The gonococcus complement fixation test of the patient's blood was twice positive. These manifestations, in addition to the history of metrorrhagia and pain,

suggested pelvic inflammatory disease of gonococcic origin. There was atrophy, partial paralysis and shortening of the left lower extremity, with resultant scoliosis and deformity of the pelvis.

The temperature on admission was 101.4 F (rectal). Hemoglobin (Sahli) was 85 per cent, red blood cells numbered 4,460,000 and white blood cells, 21,000 per cubic millimeter. The differential count showed polymorphonuclear leukocytes, 81 per cent, lymphocytes, 13 per cent and mononuclears, 6 per cent. The platelets and red blood cells were normal in appearance. On four examinations of uncatheterized urine specimens a slightest possible trace of albumin, by the nitric acid ring test, and a small number of white blood cells were found. When the patient was admitted, a tentative diagnosis of septicemia was made. A blood culture taken at that time on beef infusion, dextrose broth and blood agar produced a growth of a gram-negative diplococcus in all four flasks of the liquid medium at the end of ninety-six hours. The solid medium remained sterile at the end of fourteen days. The organism from the first subculture was agglutinated by both the New York and the Massachusetts State polyvalent antimeningococcus serum in a dilution of 1 to 80. In a dilution of 1 to 160 there was slight agglutination with New York State

Fig. 2—A dark red petechia on the dorsum of the interphalangeal joint of the right thumb became raised, rounded and developed a gray center forming a pustule.

serum. Controls with normal horse serum and Parke Davis polyvalent antigenococcus serum showed no agglutination. Incubation was maintained for one hour at a temperature of 50 C. A control with the patient's serum against a known culture of meningococcus was not carried out. The isolated organism showed other characteristics of the meningococcus. It did not grow at room temperature, it grew poorly in subcultures and only on enriched mediums; it fermented both dextrose and maltose but did not ferment saccharose and lactose.

About twenty-four hours after admission the patient complained of pain in the right thigh. There developed a diffuse swelling with induration, redness, and tenderness on the lateral aspect of the right thigh. There was no fluctuation, and roentgen examination showed no soft tissue destruction or abnormalities of the femur. This condition subsided in four days. The temperature rose to 102 F on the fourth day, having reached normal on the morning of the third day. On the fifth day the temperature was 101 F but for the following eleven days ranged between 98 and 100 F. From the third to the eighth day 8 Gm of sodium salicylate was given daily. There were migratory joint pains in the fingers and knees and migratory swelling, redness and tenderness of the fingers persisted for several days. On numerous occasions pain and tenderness over the long bones was noted. On the twelfth

day the patient developed nonprojectile vomiting, unaccompanied by nausea or headache. Fluids were given subcutaneously, and gastric lavage was done with slight improvement. Repeated examinations showed no positive neurologic signs, excepting the old paralysis of the left lower extremity. Anti-meningococcus serum therapy was deliberately withheld because the temperature was practically normal, the white blood cell count was only slightly elevated, and there were no longer definite signs of blood stream infection. A blood culture taken on the twelfth day was sterile. The cause of the vomiting could not be determined. On the morning of the seventeenth day the patient noticed diplopia. A thorough neurologic examination showed no changes. The temperature was only 100 F, but the white blood cell count had increased from 13,000 to 21,000 per cubic millimeter. With the possibility that the diplopia and vomiting were signs of early meningitis, a lumbar puncture was performed, with completely negative spinal fluid examination. However, 20 cc of New York State antimeningococcus serum was given intrathecally, 40 cc intravenously, and 20 cc intramuscularly. Two days later 65 cc was given intravenously and 15 cc intramuscularly. On the three following days 20, 60 and 60 cc, respectively, was given intravenously. The day following the last injection of serum moderately severe serum sickness developed, lasting about twelve days. The diplopia and vomiting disappeared in two days after serum therapy was instituted. After recovery from serum sickness the patient was considered to be well. However there was vomiting on two occasions following dietary indiscretion shortly before her discharge from the hospital forty-three days after admission.

The patient was readmitted to the hospital three weeks later with another attack of acute tonsillitis. She had been fairly well during the interim but had occasionally vomited after meals. Except for the absence of skin lesions, joint involvement and evidence of pelvic inflammatory disease, the physical examination was the same as on the first admission. The temperature was 102 F (oral) but returned to normal in eighteen hours. The white blood cell count was 15,000 per cubic millimeter and the hemoglobin and red blood cell count were unchanged. Lumbar puncture gave normal results. Blood culture and the gonococcus complement fixation test were negative. Throat and nose cultures showed no significant organisms. A smear from the cervix uteri was negative for intracellular gram-negative diplococci. The sore throat quickly subsided, and the patient was discharged from the hospital in one week.

There were at least three subsequent mild attacks of tonsillitis until tonsillectomy was performed, Dec. 28, 1933, under local anesthesia. The patient is being followed in the outdoor department and has remained well, except for occasional vomiting after meals, unaccompanied by nausea or pain. Gastric analysis and roentgen examination of the gastro-intestinal tract by barium meal and enema were normal. The cause of the vomiting is believed to be psychic.

COMMENT

The first case is a classic example of chronic meningococcemia with the triad of intermittent chills and fever, arthralgia and skin eruptions. A total of 1,275 cc of specific polyvalent antimeningococcus serum was administered intravenously and subcutaneously, with ultimate recovery of the patient. In view of the tendency of many patients with meningococcemia to recover spontaneously, failure to obtain immediate improvement with serum therapy in this case prevents one from concluding that there was any beneficial effect.

In the second case the onset of a chill fever, joint pains and petechiae accompanying an acute infection of the upper respiratory tract suggested a septicemia. This opinion was confirmed by growing the meningococcus in the blood culture taken twenty-four hours after the onset of symptoms. Subsidence of the acute symptoms suggested beginning spontaneous recovery before serum therapy was instituted. However, in the early stages of chronic meningococcemia there may be

afebrile asymptomatic periods of several days' duration. It is therefore possible that fever and chills of chronic meningococcemia would have developed had serum been withheld longer. Serum therapy that appears successful may fail to eradicate the infection completely. Specific serum was administered in one reported case¹ but fulminating meningitis developed nine months after apparent recovery from a meningococcemia with intermittent fever of two months' duration.

The one death in our four cases was due to terminal meningitis, which developed after seven months of intermittent fever. Antimeningococcus serum was not given, because the isolated organism was thought to be a gonococcus.

Although beneficial effects of specific serum therapy in meningococcemia are not always demonstrable, it is believed that intensive intravenous treatment with polyvalent antimeningococcus serum should be given, regardless of the course of the symptoms or the inability to isolate or agglutinate the organism.

TOXIC CIRRHOSIS OF THE LIVER

REPORT OF A CASE DUE TO LONG CONTINUED
EXPOSURE TO CARBON TETRACHLORIDE

CHARLES A. POINDEXTER, M.D.

Harriet Weil Fellow in Medicine

AND

CARL H. GREENE, M.D.

NEW YORK

Many chlorinated hydrocarbons have a toxic action on the liver. Of these, chloroform (CHCl_3) is the best known. Carbon tetrachloride (CCl_4) is closely related chemically to chloroform and likewise is a hepatic poison. Because of its noninflammable character and because it is an excellent solvent for fats and greases, it is extensively used in industry.¹ It has been introduced into the home as a fire extinguisher and a dry cleaner under the trade names of "Pyrene" and "Carbona." It is sometimes used by hairdressers as a dry shampoo. It has supplanted such inflammable liquids as naphtha and gasoline in many commercial dry-cleaning plants. It is widely used in medicine as a vermifuge in the treatment of hookworm disease.

Many cases of acute poisoning have now been recorded following the inhalation of the fumes of carbon tetrachloride.² This may produce only a slight dizziness or nausea, but in severe cases death ensues. Occasionally after oral administration as a vermifuge a lethal quantity has been absorbed from the bowel.³ In many of these fatal cases death is due to an acute toxic necrosis of the liver with the clinical picture of acute yellow atrophy. Several investigators, among them Gardner, Lamson and their co-workers,⁴ have reported the experimental production in animals of acute hepatic injury by the administration of carbon tetrachloride, either orally, intravenously or by inhalation, so that

the substantial identity of the clinical and the experimental lesions is accepted.

In addition to this acute injury, Bollman and Mann⁵ have shown that hepatic cirrhosis can be produced in dogs by the repeated administration of small doses of carbon tetrachloride over a prolonged period of time. This observation of Bollman and Mann has since been confirmed by Lacquet,⁶ Higgins⁷ and Hartman.⁸ The clinical counterpart of the latter condition, that is, chronic carbon tetrachloride poisoning with hepatic cirrhosis, has not previously been reported so far as we have been able to determine. Butsch⁹ has described a case in which ascites developed in a man after he was exposed, over a period of six months, to the fumes of carbon tetrachloride while cleaning telephone parts. In addition to the ascites there was a definite lipemia and a great increase in the cholesterol content of the serum, such as Rosenthal and Lillie¹⁰ and McMahon and Weiss¹¹ found associated with acute carbon tetrachloride poisoning in experimental animals and in human beings. There were no other clinical manifestations, and various tests for hepatic function gave normal responses. The observations in the case of

Fig 1—Gross specimen showing nodular surface and lobulations of cut surface.

Butsch are suggestive of cirrhosis but not conclusive, for the possibility of a subacute toxic injury of the liver cannot be entirely excluded.

In the present case the history, the physical signs and the laboratory observations were sufficient to permit the diagnosis of cirrhosis of the liver, this diagnosis being confirmed at necropsy. The history in reference to carbon tetrachloride is highly significant.

REPORT OF CASE

History—A man aged 46, an Italian, presented himself at the hospital, May 10, 1933, because of "swelling of the stomach" of three months' duration.

For the past eleven years the patient's occupation had been that of a cleaner of clothes. His work consisted of washing

clothes in an open receptacle in a small, poorly ventilated room. The cleaning fluid used since 1928 was a mixture of 55 per cent of carbon tetrachloride and 45 per cent of naphtha and benzine. During this period many other men had attempted to work with him, but none could continue because they soon became ill, with loss of appetite, diarrhea and vomiting. One worker, according to the patient, had "turned yellow." Many times during this period the patient had had spells of nausea and vomiting and had had severe vertigo when he worked with the cleaning fluid for any period of time. He insisted that although he occasionally had wine to drink with his meals, he

Fig 2—Cross section under low power showing lobulations and infiltration of connective tissue

never drank spirituous liquors. The rest of the past history was unimportant.

He had had difficulty for three years with what he termed "gas on the stomach." Flatulence and a sensation of epigastric fulness and distention followed the ingestion of food and was temporarily relieved by catharsis and occasionally by sodium bicarbonate. He had had dull aching pains, localized in the right upper quadrant of the abdomen for a year. This usually appeared after a heavy meal or after eating greasy food. Three months before admission this pain had been more severe and he noticed that there was considerable tenderness over the area of pain. Coincident with the onset of tenderness and increase in pain, the abdomen began gradually to increase in size. He had occasional epistaxis. Constipation and gas formation were marked. He also noted that while his weight had remained stationary, his arms, face and chest had become thinner. He felt tired all the time and did not have enough strength to work.

Physical Examination—The patient was dark complexioned and had a quite sallow appearance, he was 5 feet 5 inches (165 cm) tall and weighed 151 pounds (68.5 Kg) (standard weight for height and age is 139 pounds, or 63 Kg). The sclerae were slightly but definitely icteric in tint. The lips and mucous membranes were slightly cyanotic. The face and arms were thin and contrasted markedly with the distended abdomen. The latter was flat on percussion throughout and had a marked fluid wave. The liver was palpable four fingerbreadths below the costal margin and was very firm. The spleen was palpable by ballottement three fingerbreadths below the costal margin. There was some venous enlargement in the superficial veins of the abdominal wall both anteriorly and posteriorly. The abdominal circumference was 39 inches (99.5 cm). The blood pressure was 110 systolic, 70 diastolic. The rest of the examination was normal.

Laboratory Examination—The fluid intake was limited to about 1,000 cc, the actual intake varying from 880 to 1,240 cc. Under these conditions the daily output of urine varied from 500 to 900 cc, with a specific gravity varying between 1.020 and 1.027. Individual urine specimens contained traces of protein and urobilin but were otherwise normal. Bile was not present.

There was a moderate degree of anemia, the hemoglobin being 73 per cent (Sahli), the erythrocytes numbered 3,810,000, and the leukocytes 7,300 with a normal differential count.

The chemical analysis of the blood revealed a blood urea nitrogen of 121 mg, sugar 82 mg, cholesterol 167 mg and cholesterol esters 77 mg per hundred cubic centimeters. The icterus index was 15 but the serum bilirubin was less than 20 mg. The van den Bergh reaction was indirect.

The galactose tolerance test, May 16, with 40 Gm. of galactose, gave a urinary excretion of 17 Gm. June 3, the excretion was 23 Gm. The bromsulphalein test, May 11, showed a retention of 30 per cent at the end of half an hour.

Gastric analysis showed the presence of free hydrochloric acid. Biliary drainage was done on several occasions. Concentrated specimens of bile were obtained each time, no crystals were in the sediment, and cultures of the bile were sterile.

Progress—The patient was placed on a high carbohydrate, salt-free diet with limitation of the intake of fat and protein. Because of the work of Minot and Cutler¹² showing the beneficial effects of calcium administration in dogs with carbon tetrachloride poisoning, 60 grains (4 Gm) of calcium lactate was given twice a day. Before mersalyl was given, ammonium chloride was administered in daily doses of 9 Gm. May 31, a dose of 1 cc of mersalyl (salyrgan) was given intravenously. The urinary output was 1,500 cc that day and 1,200 cc on each of the two succeeding days. June 3 a second injection of mersalyl was given with a diuresis of 2,000 cc during the following twenty-four hours.

There was marked improvement while the patient was in the hospital. He felt much stronger. The girth of the abdomen decreased to 33 inches (84 cm). The weight decreased from 151 pounds to 134 pounds (61 Kg). With the disappearance of the ascites, the liver and spleen could be palpated with ease, the apparent size being the same as on admission. The patient was discharged from the hospital in good condition after twenty-five days.

The patient continued to improve in strength for several months and was free from edema and was able to do light work. Examination in September indicated that the liver was palpable at the costal margin, while the spleen could no longer be felt. September 20 a bromsulphalein test showed a retention of 50 per cent of the dye at the end of thirty minutes, suggesting that the hepatic lesion was progressive. About this time and contrary to medical advice, he returned to work at cleaning

Fig 1—Cross section under high power showing swollen liver cells, leukocytic infiltration and cutting off of cell groups by invading fibrous tissues

clothes and was again exposed to fumes of carbon tetrachloride. A few weeks later he began to have "gas" and abdominal distress after eating, and the abdomen became progressively larger. November 7 his weight was 144 pounds (65 Kg) and examination showed the presence of a moderate degree of ascites. He was again given ammonium chloride and a series of injections of mersalyl. The diuretic response was unsatisfactory, and the ascites became progressively more marked. November 23 he was readmitted to the hospital. His

12 Cutler J T The Influence of Diet on Carbon Tetrachloride Intoxication in Dogs J Pharmacol & Exper Therap 45 209 226 (June) 1932 Minot A S and Cutler J T Guanidine Retention and Calcium Reserve as Antagonistic Factors in Carbon Tetrachloride and Chloroform Poisoning J Clin Investigation 6 369 (Dec) 1928

weight was 145 pounds (65.8 Kg). Abdominal paracentesis of 9,000 cc of clear, straw-colored fluid was done. When discharged the following day his weight was 136 pounds (61.7 kg). The paracentesis gave temporary relief but the ascites recurred within a few days and could no longer be controlled by medical means. He was readmitted to the hospital and a second paracentesis was done, December 12, 3,500 cc of fluid being removed. Following paracentesis, 2 cc of mersalyl was given intravenously. The fluid intake the succeeding twenty-four hours was 1,000 cc and the urine output 2,000 cc. In spite of frequent injections of mersalyl following his discharge from the hospital, the ascites recurred. The patient was readmitted to the hospital and a paracentesis of 6,000 cc was done, December 28.

Because of the inability to control the ascites further by medical therapy, an exploratory laparotomy was decided on. It was performed by Dr. Erdmann, December 29. A large amount of ascitic fluid was present in the peritoneal cavity; the liver was markedly cirrhotic, and the spleen was hypertrophic. A splenectomy was done and the omentum implanted into the abdominal wall.

Following the operation the patient did not rally. The pulse and temperature became progressively elevated and he died three days after operation.

At necropsy, advanced hepatic cirrhosis, postoperative hemorrhage and old infarcts of the right kidney, with compensatory hypertrophy of the left kidney, were found.

Pathologic Examination.—The spleen weighed 600 Gm and measured 205 by 100 by 51 mm. It appeared to be slightly firmer than normal. On section the pulp was bright red with a few gray streaks. The follicles were not conspicuous.

Microscopic examination showed the splenic follicles to be 1 to 2 mm in diameter and rather inconspicuous in the hypertrophied spleen. The enlargement of the spleen was due chiefly to dilatation of the venous sinuses and an increase of reticulum in the walls of these sinuses. They were rather stiff so that they remained distended in the fixed specimen. There was also an increase of fibrous tissue and apparently of smooth muscle in the capsule of the spleen and in the trabeculae that extended into its substance. The cellular structure appeared not to be disturbed qualitatively. Our pathologic diagnosis was splenomegaly of chronic passive congestion.

The liver measured 15 by 21 by 7 cm and weighed 1,135 Gm (fig. 1). Its surface was irregularly nodular; the individual nodules varying from 5 to 10 mm in diameter raised from 2 to 4 mm above the liver surface. They were grayish brown to reddish brown and were separated by irregular branching strands of grayish white tissue. The capsule was smooth and glistening. On section the organ cut with a well marked increase in resistance. The cut surface consisted of irregular islands of grayish brown parenchyma surrounded by diffusely branching strands of connective tissue.

Microscopic examination showed the external capsule of the liver to be about 0.5 mm in thickness with very coarse bands of connective tissue extending from it into the substance of the organ. These bands entirely surrounded small lobules of hepatic tissue in some places (fig. 2). The strands of fibrous tissue in some places were richly infiltrated by abundant lymphocytes. The bile ducts were slightly increased in number. Occasionally they contained small clumps of exfoliated epithelial cells, but on the whole the bile ducts appeared normal and there was no evidence of excessive inflammatory infiltration about them. The change in the liver appeared to be due to destruction of the hepatic cells, with a compensatory hyperplasia of the remaining hepatic elements. In this way numerous small lobules which were highly irregular in shape and which were partly or entirely surrounded by bands of connective tissue more or less richly infiltrated by lymphocytes had been formed (fig. 3). The hepatic cells themselves appeared to be larger than normal and occasionally contained giant nuclei. Our pathologic diagnosis was chronic hepatitis and cirrhosis.

COMMENT

The patient presented sufficient evidence for the clinical diagnosis of hepatic cirrhosis and this diagnosis was confirmed at necropsy. The various agents that have been suggested as possible causes of cirrhosis are

legion. The experimental production of hepatic cirrhosis in animals by chronic intoxication with carbon tetrachloride has been amply proved. The patient was exposed to the fumes of carbon tetrachloride over a prolonged period and it seems reasonable to conclude that, while the amounts inhaled were insufficient to produce a violent toxic reaction at any one time, they nevertheless caused a diffuse destruction of hepatic tissue with resultant fibrosis and cirrhosis. In view of the history and in the absence of evidence implicating other etiologic factors, we believe that this case represents the clinical counterpart of the experimental lesions previously referred to and therefore is a valid example of hepatic cirrhosis due to chronic poisoning by carbon tetrachloride.

Exposure to the fumes of carbon tetrachloride in the dry cleaning of clothes, as pointed out recently,¹³ is quite common. When this practice is carried out at home under usual conditions, only small amounts of cleaning solution are used, ventilation is adequate and the exposure is occasional and of short duration. In commercial practice, on the other hand, large quantities of carbon tetrachloride are used and, unless ventilation is adequate and care is taken to prevent inhalation of fumes by the workman, may involve frequent or continuous exposure to the fumes over prolonged periods.

The industrial hazards associated with the use of carbon tetrachloride have recently been reviewed by McCord,¹⁴ who stresses the danger of acute poisoning. The present case demonstrates that, with exposure to the fumes over a prolonged period, chronic poisoning may develop as an additional industrial hazard.

A TYPICAL HEREDITARY SYNDROME

DYSTROPHY OF THE NAILS, CONGENITAL DEFECT OF THE PATELLA AND CONGENITAL DEFECT OF THE HEAD OF THE RADIUS

BERTA ASCHNER, M.D.

VIENNA, AUSTRIA

Turner¹ has reported the very interesting history of two families in both of which "arthrodysplasia" associated with dystrophy of the nails has occurred as a dominant mendelian character through four generations. The author attempted to clarify the facts from a genetic point of view. Probably he was not familiar with the literature on the association of dystrophy of the nails with skeletal anomalies, since he suggested one pathologic hereditary factor for his first family in which all the affected members showed both anomalies. For the other family, in which several members presented only dystrophy of the nails, he postulated two different pathologic factors, one of which (the factor for arthrodysplasia) manifested itself only when the other factor was also present. Besides, the author thought there was a possibility that there existed a third factor, which, whenever it was present, inhibited the factor for arthrodysplasia, so that only the nail dystrophy would be manifested in cases of this kind.

1 Turner J W An Hereditary Arthrodysplasia Associated with Hereditary Dystrophy of the Nails J A M A 100 882 (March 25) 1933

There are two very important reasons against this hypothesis of Turner's. First, one cannot assume essentially different laws for the representation of hereditary characters in the genotype (that is, the sum of all the potential hereditary factors present in the fertilized ovum) in different families. A factor may be more prevalent in one family and less in another, this is perfectly true and may often be observed. However, to believe that a phenotypic hereditary attribute that is represented once by only one genotypic unit might be represented in another case by several different factors in the same species would be contrary to all hitherto known laws of experimental and human genetics. Therefore, whenever a hypothesis is constructed on the genotypic representation of phenotypic characters in human pathology, one explanation must be sought that will be satisfactory for all the observed facts.

The second reason why I cannot agree with Turner's concept is that if two factors are assumed for all the cases, the fact must be explained that usually the two anomalies are inherited together as if they were one. The author tried to explain this by the hypothesis that the factor for the skeletal condition would be manifested only when the factor for the nail anomaly was also present. This assumption is not consistent with a large number of observations in analogous cases in the literature.

When Turner stated that the deformity he described had "never been reported previously," he was right as far as the specific joint anomalies with their different details were concerned. He overlooked, however, several cases in the literature, which I shall refer to later. As a matter of fact, a number of very similar observations have been known. The striking characteristics of Turner's cases are (1) disorders of the nails varying from the total absence of the nail to one that is only a little thinner than normal, always affecting more severely the thumb nail and becoming less marked toward the little finger, (2) defect or at least severe hypoplasia of the patella and large internal condyle of the femur, (3) deformities of the elbow, large prominent internal condyle and other more trivial anomalies of the humerus. In regard to the head of the radius, the author admitted only that it was unusually small, but it is evident from the roentgenograms (fig. 4 in Turner's paper) that there was also a luxation of the head of the radius, (4) hypoplasia of the scapula and of the features of the head of the humerus, (5) slight congenital deformities of the hip joints and anomalies of the ankles, the malleoli being enlarged and the internal one being larger than the external one.

Three of these anomalies and the three most striking ones form in themselves an already well known syndrome, that is, anonychia with congenital defect of the patella and congenital luxation of the head of the radius. The latter need not be present, as there exists also a large number of cases in which only the defect or hypoplasia of the patella is associated with the defect of the thumb nail. This association—obviously the slightest form of this syndrome—is a typical one and is usually found in several members of the same family. The two anomalies are inherited together, so that usually the affected members are afflicted by the two at the same time. Still, there are rare exceptions individuals who may show only the one or the other defect.

In 1928 in the course of a study on genetics of the human skeletal system I² was able to gather from the literature the history of eight families in which congenital defect or hypoplasia of the patella was inherited through several generations. Incidentally, I wish to mention that when I refer to the defect of the patella I mean the isolated one in which the neighboring bones are intact—a rather rare anomaly. In cases of a defect of one or more of the long bones of the leg, the patella is very often lacking too, but these cases are not of interest here. Among the eight families with hereditary isolated congenital absence of the patella there were three³ in which the bone defect was associated with a hereditary defect of the thumb nails in all the affected members of the family. As far as I could ascertain (Little's³ paper in the original was not accessible), the two anomalies always occurred together in the same individual, with one single exception. In the case described by Rubin,³ a boy whose patella was absent had perfectly well developed nails. His sister and mother were afflicted by both deformities and his maternal grandmother had had no thumb nails but there was nothing known about the patellas. At that time I was concerned only with hereditary anomalies of the bones and so I did not mention a case of Most⁴ with defect of the thumb nails and only rudimentary development of the other nails in a child, in four of his sisters and brothers, in his father, in the five paternal uncles and in the paternal grandmother. The child showed, among other deformities that do not belong to the syndrome here discussed (clubfoot on one side, talipes calcaneovalgus on the other, contracture of the hip and knee joints and so on, which probably are at least partly due to exogenous causes, being present only occasionally in the same individual), a congenital defect of the patella, which of course was not due to exogenous factors. The other members of the family with anonychia were not examined. It seems rather probable that at least in some of them the patella was also lacking. This is the more plausible as it is known that a defect of the patella may not produce any disturbances for the individual and very often he does not even know about this defect.

Since my publication I have come to recognize, in addition to this typical duality—defect of the patella and thumb nail—a somewhat broader syndrome. There exist a few more families in which is inherited not only the defect of the thumb nail but also the dystrophy or partial defect of the other nails, as shown in the case of Most. There is not only defect of the patella but also other anomalies of the joints, particularly luxation of the head of the radius and other less striking, less constant and less characteristic deformities. The first of these cases had been reported before my first paper on this subject was published. As this was the only case known at the time, the association of anomalies as a typical syndrome did not occur to me. It was Trauner and Rieger⁵ who published this pedigree with congenital luxation of the head of the radius and dystrophy of the nails in six members of four generations. One of the patients also had a hypoplasia

of the patella. In addition, there were signs of slight arthrosis deformans⁶ of the knee joints and a camptodactylia (congenital contraction of the fifth and fourth finger) which were inherited in this family. Later on, Oesterreicher⁷ observed a case in which eleven members in five generations of the same family were affected with congenital defect of the thumb nail and the patella. The latter was not quite certain in two of them. In seven members there were also to be found a deformity and congenital luxation of the head of the radius on both sides, in one individual this was present only in the right arm and in three others it was not known whether there was also a deformity of the elbow joint or not. The anomaly of the joints alone did not occur in that family, as shown in the accompanying diagram. It was only a short time ago that I learned of the two more analogous pedigrees of Turner's

Having related all the facts that it has been possible to obtain to date regarding this syndrome, I shall try to explain the genetic connections and reasons for the phenotypic facts, searching of course for a supposition that will explain satisfactorily all the observations that have been made. As I was aware of only the typical association of the defect of the patella and thumb nail in 1928, I assumed two different pathologic genotypic factors that were responsible for these two anomalies, since each of them might occur alone without the other. In my own table, previously mentioned, I quoted five families in which only a defect of the patella was inherited, the nails being perfectly normal. On the other hand I know from the literature quite a number of cases of hereditary dystrophy and defect of the nails (Tobias,⁸ Ebstein,⁹ Pires da Lima,¹⁰ Hofmann¹¹ and others), in some families associated with congenital alopecia (Nicolle and Halpre,¹² Barrett,¹³ Jeanselme and Rime,¹⁴ White,¹⁵ Jacobsen¹⁶ and others) but without any skeletal anomalies in the whole family. It is therefore obvious that there must exist at least two separate pathologic factors in the genotype, so-called genes, which produce the two anomalies.

The next problem is Why do these deformities occur so frequently together and why are they, once they are both present in a family, always inherited together with very rare exceptions, almost as if they were one factor? For the explanation of the latter fact I previously assumed a linkage between the two genes, which means that they would be situated in the same chromosome. It is known from experimental biology that genes localized in the same chromosome are inherited together like one unit, with a few exceptions, which are caused by certain irregularities in the mitotic division of cells the so-called crossing over. T. Morgan and his school have studied these relations for a great many characters of *Drosophila* with excellent success, and they were

able to plot a geographic map of the situation of many genes in the chromosomes of *Drosophila*. Of course, knowledge is still far distant from that exactitude in human pathology. Since the fundamental laws of heredity are naturally the same for all kinds of individuals whose cells undergo mitotic division, it is obvious that linkage must also play a big role in the heredity of man. This results from the very fact that the number of different genes or hereditary units in man is an enormously large one, while the number of chromosomes probably is twenty-four, or may even be only twelve, and therefore every chromosome must necessarily contain a great many different genes, which are consequently linked together. One example of linkage in man is known for sure that is, the so-called sex-linked characters. In view of this, one certainly has a right to assume a linkage between the two pathologic genes in question.

There is still another problem to be solved. It is understood why the two anomalies, once being present in an individual are inherited together. But why are they to be found so comparatively often in the same

Oesterreicher's pedigree. P defect of the patella N defect of the thumb nails R luxation of the head of the radius

family? With such rare deformities as these two, it cannot be merely chance if out of eight families with defect of the patella three are also affected by the defect of the thumb nails or, if Most's case and the others with the whole syndrome are counted, there are seven families among twelve showing both anomalies. In order to understand this better, one might ask the question. If, for example, an individual with a congenital defect of the patella contains in his genotype a gene producing this anomaly, what is to be found instead in the genotype of a normal individual? This must include somewhere the normal "allelomorph" of that pathologic unit which is a gene for the right development of the patella. In an analogous manner one must conclude of course, that a physiologic gene exists for the normal development of the nails in the genotype. If one of these factors is altered in a certain way, the pathologic gene in question occurs. Now the problem may be considered like this. Why are these two normal genes so often and easily altered at the same time? Julius Bauer had assumed that different genes have the more probability to show pathologic mutations at the same time, the closer they are localized together within the chromosome, as any damage occur-

6 This expression is now generally used in the German literature to characterize the degenerative, consumptive processes of the joints in opposition to the inflammatory ones.

ring to one of them and changing it into its pathologic allelomorph may most easily involve its nearest neighbors. So I postulated in 1928 that the genes for defect of the patella and the thumb nail were not only linked together in the same chromosome but are even very near neighbors to one another within the chromosome. This seems to me the more plausible, as it is known indeed from Morgan's studies that every gene has its own particular place within the chromosome and that linked genes, the closer they are placed together, show a less frequent tendency to be separated by crossing over. Since crossing over is very rare in my case, a very near relationship must be assumed. This hypothesis of the very close neighborhood between the two linked factors in question entered into the American literature through my chief, Julius Bauer,¹⁷ who has discussed this concept in several lectures.

There is no difficulty whatever in explaining the new facts that have been learned from the observations of Trauner and Rieger, Oesterreicher and Turner. Here is an additional third constant, hereditary symptom, the luxation of the head of the radius. This deformity has been observed occurring as a hereditary anomaly alone without the other two deformities (Hoeftmann-Weszkalnys,¹⁸ Weszkalnys,¹⁸ Servier,¹⁹ Princtau,²⁰ von Sury,²¹ Dencks,²² Sieber,²³ and others). It is obvious, therefore, that there exists a third pathologic factor causing the congenital luxation of the head of the radius. This factor is likewise closely linked to the other two, as the three symptoms are inherited together with few exceptions. Probably the neighborhood of this third gene to the others is not quite as close as the one previously mentioned, as the whole syndrome does not occur quite so often as the association of the defect of the thumb nail and the patella. The other anomalies of the joints described in these families are far too variable for one to analyze certain genes, and not much more can be said at present than that a constitutional inferiority of the joints seems to belong to this syndrome.

As the hereditary camptodactylia in the family of Trauner and Rieger is also seen only in the members affected with the syndrome, it may be assumed that this pathologic gene, which is inherited together with the others, is localized in the same chromosome but is not in an unusually close contact with them. I should not be surprised to find, occasionally, in families with such obvious anomalies in the germ plasma other signs of constitutional deviation as well. Accordingly, it has been seen that in Oesterreicher's family there are quite a number of neuropathic and psychopathic individuals.

I hope I have shown that my assumption—linkage with close neighborhood of the linked characters of several different hereditary pathologic factors—can satisfactorily explain all the clinical data and facts that are known up to the present about the pathologic condition here discussed. Turner's hypothesis could never explain either the cases with hereditary defect of the patella alone or the families with congenital luxation of the head of the radius without dystrophy of the nails. Trauner and Rieger, in discussing only their own pedigree, assume for this case a polyphenia that

means one single hereditary unit in the genotype which produces several different and disconnected signs in the phenotype. Such a polyphenic pathologic factor would certainly clarify the case of Trauner and Rieger, but it would not account for all the other observations as, in the case of polyphenia, the singular phenotypic symptoms could never occur separately. On the contrary, whenever one of them is present, the others have to be there too. I hope that I have succeeded in showing clearly that each of the symptoms may occur alone and independent as a hereditary character, as well as two or three joined together.

It is rather curious, therefore, that even Oesterreicher, who is well acquainted with the related literature, accepts the hypothesis of polyphenia. In my opinion this may be understood by the fact that this author, a neurologist, did not feel sufficiently secure in genetics to form an opinion of his own in regard to the genotypic connections of the observed symptoms. He therefore sought the advice of Paula Hertwig, the biologist. Hertwig, on the other hand, was naturally not familiar enough with the clinical facts, which would make a polyphenia impossible. She derived her theory chiefly from the striking cases presenting the whole syndrome and she argued that a linkage was not probable because that would not explain why the two linked genes should show a pathologic mutation so frequently at the same time. This difficulty is resolved by the assumption of the very close neighborhood in the chromosome. When Oesterreicher declines the linkage on account "of the impossibility of an exact proof in man," it seems rather strange, as the proof cannot be any more exact for the polyphenia than for any other genotypic connection in man. It is rather more likely that a proof can be found for the linkage, as I have already shown that the existence of linkage even in man is very plausible and quite sure for the sex-linked characters. It must not be forgotten that the scientific methods of genetics in man are quite different from those of experimental biology, and only a clinician well acquainted with clinical facts and familiar as well with the biologic laws and progresses of genetics will be able to solve the problems of human genetics.

Vienna IX, Hebragasse 5

Calmness Amid Storm—In the first place, in the physician or surgeon no quality takes rank with imperturbability, and I propose for a few minutes to direct your attention to this essential bodily virtue. Perhaps I may be able to give those of you, in whom it has not developed during the critical scenes of the past month a hint or two of its importance, possibly a suggestion for its attainment. Imperturbability means coolness and presence of mind under all circumstances, calmness amid storm, clearness of judgment in moments of grave peril, immobility, impassiveness, or, to use an old and expressive word, phlegm. It is the quality which is most appreciated by the laity though often misunderstood by them and the physician who has the misfortune to be without it, who betrays indecision and worry, and who shows that he is flustered and hurried in ordinary emergencies, loses rapidly the confidence of his patients. In full development, as we see it in some of our older colleagues, it has the nature of a divine gift, a blessing to the possessor, a comfort to all who come in contact with him. You should know it well, for there have been before you for years several striking illustrations, whose example has, I trust, made a deep impression. As imperturbability is largely a bodily endowment, I regret to say that there are those amongst you, who, owing to congenital defects may never be able to acquire it. Education, however will do much and with practice and experience the majority of you may expect to attain it to a fair measure.—Sir William Osler

Clinical Notes, Suggestions and New Instruments

PREVENTION OF SCARLET FEVER

MATTHEW MOLITCH M D JAMESBURG N J

There is still present, in the minds of many general practitioners, a doubt of the value of immunization against scarlet fever. In the New Jersey State Home for Boys, routine Dick tests are done on every boy admitted and all boys with a positive reaction are treated with *Streptococcus scarlet fever* toxin prepared according to the Dick method. Five doses, consisting of 500, 2,000, 8,000, 25,000 and 80,000 skin test doses, are given hypodermically at weekly intervals. The accompanying table gives the incidence of positive reactions in 3,025 Dick tests. All the tests during the last nine years were done by Dr G F Leonard of the Biological Laboratories of E R Squibb & Sons, which eliminates a possible source of error. An intradermal injection of 0.1 cc of standard scarlet fever toxin, containing one skin test dose, was given in each case and a reaction of 1 cm or more was considered positive.

Our percentage of positive cases (15.5) is rather low but understandable when one considers the strata of society from which our boys come. They have probably been immunized to most infections during earlier childhood. Our boys range in age from 8 to 17 years and are committed only from the state of New Jersey. Melnick,¹ in a study of the children in the St John's Orphanage in Philadelphia, found an incidence of 17 per cent positive, while Bull,² in an analysis of his private patients, found an incidence of 83 per cent positive. The latter group was described as privileged children who have been sheltered from infection.

An analysis was made of a group of patients, all of whom were treated by me and who remained in the institution long enough to be retested after treatment. One hundred and seven boys comprise this group. Eighty-five were tested once from three to seventeen months after treatment was completed, while twenty-two were tested twice from sixteen to thirty months after treatment was completed. Two boys were found to have positive reactions ten and seventeen months respectively after treatment. This gives an incidence of success in 98.2 per cent. Both were given an additional course, and one became negative while the other left the institution before he was retested.

Incidence of Positive Dick Tests

Year	Total	Negative	Positive	Positive per Cent
1925	669	444	125	21.0
1926	77	62	15	19.4
1927	312	275	37	11.8
1928	317	266	51	16.0
1929	306	260	46	15.0
1930	404	335	69	17.0
1931	302	259	43	14.2
1932	319	283	36	11.2
1933	419	371	48	11.4
Grand totals	3,025	2,500	525	15.5

There have been some slight reactions to immunization chiefly headache, fever, occasionally nausea and vomiting and rarely rheumatic pains. Scarlatinal eruptions were not noted in any of our cases but peculiarly were noted in two boys following tetanus antitoxin given for prophylactic purposes. Of the 107 boys 12 were admitted to the institution hospital an incidence of 11.2 per cent. Seven boys were admitted once during the five weekly treatments, while four were admitted twice and one boy was admitted three times. It should be stated that boys are admitted to the hospital particularly because of elevation of temperature or for any reason that temporarily handicaps their academic or vocational training.

No precautionary measures were given to decrease the incidence of reactions because of their minor character. Melnick¹

¹ Melnick Theodore. Prevention of Scarlet Fever. Arch. Pediat. 50: 158 (March) 1933.

² Bull H G. Report on a Group of Fifty Children Dick Tested Eight Years After Immunization Against Scarlet Fever. J. A. M. A. 101: 363 (July 29) 1933.

outlined a precautionary procedure which the average practitioner might not care to use, because of its resemblance to a preoperative routine. During the past three years two cases of scarlet fever occurred in the institution. One was in a boy who had a positive Dick test and was awaiting treatment, while the other was in a nurse who had not been Dick tested.

CONCLUSIONS

- 1 Three thousand and twenty-five boys were Dick tested, with an incidence of 15.5 per cent positive reactions.
- 2 An analysis was made of 107 treated cases, with an incidence of success in 98.2 per cent.
- 3 Twelve boys (11.2 per cent) were admitted to the institution hospital because of reactions, chiefly elevation of temperature.
- 4 No case of scarlet fever developed in negative Dick cases or in treated positive cases. One case developed in an untreated positive.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M D
CHICAGO

NOTE.—In their preparation these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr Bernard Fantus. The views expressed by various members are incorporated in the final draft prepared for publication. The series of articles will be continued from time to time in these columns.—Ed

THERAPY OF TETANUS

PROPHYLAXIS

1 *Medical, Surgical and Obstetric Asepsis*—Tetanus has followed infection from hypodermic injection, especially of tissue-destroying drugs (such as quinine) and if made into the lower extremity. It has occurred also after vaccination. Infection may occur from blisters on the feet, from the umbilicus in the new-born infant, from bed sores contaminated by feces, and from burns. Wound discharges of patients with tetanus are infectious, hence care must be taken to prevent inoculation of others. Even though in actual practice such transmission is rare, patients with tetanus are best treated by a special nursing and medical group, trained to give constant and adequate care.

2 *Treatment of Contaminated Wounds*—Under local or general anesthesia, as needed, the wound should be incised, if this is required, to remove all foreign bodies (dirt, clothing, bone denuded of periosteum). Cleansing with soap and water, should be followed by liberal use of solution of hydrogen dioxide. For wounds that cannot be rendered aseptic by cleansing and debridement, the Carrel-Dakin technic of wound disinfection is probably best. Cauterization should never be done, as necrotic tissue favors the growth of tetanus germs. The skin surrounding the wound should be painted with tincture of iodine to produce and maintain hyperemia.

3 *Antiserum*—In all cases in which earth or street dirt has entered the tissues, one should inject 10 cc (1,500 units) of antiserum subcutaneously near the wound as soon as possible (from 0.5 to 1 cc first and wait three or four minutes for possible reactions before injecting the remainder of the dose). If there is a large, dirty, macerated wound, the minimum initial dose should be 5,000 units. A second dose should be given within ten days, as immunity lasts for only seven

to ten days. Children are given half of the adult's dose. Should a secondary operation become necessary, the prophylactic dose should be repeated, but care should be taken first to desensitize the patient to horse serum.

TREATMENT

1 *Antispasmodic* — For patients admitted with spasms, securing of immediate and prompt relaxation is imperative. Tetanic spasms should be controlled and continuous sleep or at least complete muscular relaxation secured to avoid respiratory muscle spasms and exhausting convulsions.

(a) Chloral hydrate, from 1 to 2 Gm every four hours (up to 10 Gm daily), may be given, preferably in starch water by rectum, and the patient kept asleep until the symptoms have abated. Instead of this, amytal sodium may be used in doses of 0.2, 0.4 or 0.8 Gm by mouth, by rectum or intravenously as required to keep the patient under moderate narcosis all the time.

(b) Morphine sulphate, 8 mg, may be given hypodermically every four hours as required to allay pain. While cyanosis is no contraindication to its use, it should be given with caution so as not to depress the respiratory center.

(c) In severe cases with recurring convulsions, magnesium sulphate should be injected intrathecally under light chloroform anesthesia. The dose is 1 cc of 25 per cent solution to each 10 Kg of body weight, for children, 0.5 cc for each 10 Kg. The patient should be kept in the horizontal position with the head slightly elevated to protect the respiratory center. The dose should not be pushed to complete relaxation but merely to the point of rest and comfort. The effect sets in within half an hour and lasts up to twenty-four hours, when the dose should be repeated (0.8 cc of solution to each 10 Kg). If respirations become slow or shallow, from 2 to 5 cc of 5 per cent solution of calcium chloride should at once be injected intravenously and the spinal canal washed with physiologic solution of sodium chloride. If necessary, artificial respiration should be kept up for hours. If spinal puncture cannot be used 25 per cent solution may be given subcutaneously (from 1 to 2 cc to each 10 Kg of weight), four times in twenty-four hours.

(d) The masseter muscles should be infiltrated with procaine hydrochloride (0.5 per cent solution) against trismus resisting other treatment.

2 *Antiserum* — This must not be given until the spasms are under control. A preliminary skin test should be given. (a) Local infiltration of the tissue (muscles) should be done some distance away from the wound with 20,000 units of antiserum.

(b) Intravenous injection with 60,000 units of antiserum should be done at the same time as the local infiltration. It is best given diluted with Ringer's solution, and by the drop method.

One must be prepared to treat anaphylaxis (q.v.) with epinephrine.

(c) Intramuscular injection is the most important mode of administration. In milder cases (those with a long incubation period or with local symptoms only) it should be given instead of intravenous injection, and, in more severe cases, following the intravenous injection, 60,000 units daily for the first two days.

(d) Intrathecal injection is given only in severe cases with trismus, under very light chloroform anes-

thesia, and after permitting from 10 to 20 cc of spinal fluid to escape, 15,000 units slowly (preferably by gravity), and repeated daily until the symptoms subside. It is well to dilute the serum in the syringe with some of the spinal fluid. Cistern injection is considered best in head injuries. The advantage of intrathecal injection is questioned.

(e) Endoneural injection may be considered in desperate cases. Its advantage has not been established.

3 *General Regimen* — Continuous and special medical and nursing care is essential.

There is constant danger of tonic spasm of the respiratory muscles, even as late as the fourteenth to the twenty-first day, which may produce fatal asphyxia. These spasms are best detected by frequent gentle palpation of the abdomen and watching the respirations as soon as the abdomen becomes rigid. The occurrence of this rigidity indicates immediate administration of more sedative even if the patient is asleep.

(a) Absolute rest and quiet in a dark room are necessary—no talking, no switching on of lights, no slamming of doors. The patient should be given an adequate sedative before being disturbed for any treatment, such as an enema or catheterization.

(b) The diet should consist entirely of liquids, as solids may cause spasm of the muscles of deglutition. If swallowing is impossible, retention enemas of 5 per cent dextrose solution should be given. Milk may be fed by gavage, later, from a bulb or a nursing bottle with large holed nipple. Intravenous or intramuscular injections of 5 per cent dextrose solution must be used, in addition, to a sufficient extent to maintain an adequate fluid income.

(c) Frequent aspiration of the nasopharynx is required in patients unconscious from large doses of sedative.

(d) A laxative, such as liquid petrolatum or castor oil, is required, as constipation is the rule.

(e) Catheterization may be demanded. The bladder must be watched for distention in all cases.

(f) The patient should be kept as comfortable as possible, as discomfort causes restlessness and even convulsions and increases the amount of sedative medication required, and with this the danger from the sedative. Sponge baths may be demanded if the patient is hot and perspiring, mentholated calamine lotion and epinephrine injections, for serum reactions.

4 *Surgical Treatment* — Here opinion is divided. Some believe that operation is not indicated after the onset of the disease excepting in rare cases. Others consider acute tetanus a surgical emergency indicating, if possible, complete excision of the focus without entering infected tissue and, if this is not feasible, wide exploration under general anesthesia for debris and foreign bodies in all cases in which the severity of the disease increases while the patient is in the hospital. At any rate, no surgery should be undertaken until after sedative and antitoxin treatment has been established.

5 *Artificial Respiration* — If enfeeblement of respirations and cyanosis manifest themselves, artificial respiration, preferably by means of a respirator, should be instituted. Asphyxia from spasm of the respiratory muscles should be prevented by adequate antispasmodic therapy, it is not amenable to the respirator. Patients kept alive for nine days have at least a 90 per cent chance of recovery.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
H A CARTER Secretary

EVEREADY PROFESSIONAL MODEL CARBON ARC LAMP REACCEPTED

In a report published in *THE JOURNAL*, Aug 15, 1931 page 462, the Council accepted for a period of one year the Eveready Professional Model Carbon Arc Lamp manufactured by the National Carbon Company, Inc., Cleveland. This lamp is designed for general radiation therapy in physicians' offices, hospitals or clinics.

The unit operates on 110-115 volts, 60 cycles, alternating circuit, and the current drawn from the line does not exceed 15 amperes. The carbons are brought into contact, separated and held at proper arc length when burning by means of a motor operated constant current arc control. The feeding of the arc is entirely automatic and the feeding mechanism is started merely by turning on the switch. The carbons are drawn together and, when the arc strikes, they separate to the correct arc length. When the carbons have burned to the minimum permissible length, the arc is automatically extinguished. The transformer mounted on the rugged stand, permits a current of 25 amperes to flow through the arc while but 15 amperes is drawn from the line.

The company claims that the unit will provide sufficient ultraviolet, visible and infra-red radiations to supply the demands of physicians practicing artificial radiation therapy. The claims in the advertising matter and descriptive literature examined by the Council conform with the Council's adopted statement "Regulations to Govern Advertising of Ultraviolet Generators to the Medical Profession." The Eveready Professional Model Carbon Arc Lamp therefore, is reaccepted and included in the list of accepted devices for the regular period of three years.

VICTOR MODEL "B" THERMO-SPECTRAL LAMP ACCEPTABLE

The General Electric X-Ray Corporation manufactures a therapeutic radiant heat lamp called the Model "B" Thermo-Spectral Lamp. It is furnished with two types of radiant energy generators—a nitrogen-filled tungsten filament bulb and a resistance (infra-red) unit. The socket in the chromium plated reflector is standard and the resistance unit can be exchanged for the bulb or vice versa in accordance with technic employed by the physician.

Victor Model "B" Thermo-Spectral Lamp

The stand is equipped with a flexible extension arm, which may be bent at any angle and retain the position given it. The arm is mounted on a sliding vertical rod, which may be adjusted for height, the over-all extension (approximately 7 feet) giving a wide range of adjustments. The shipping weight is 55 pounds.

The unit was investigated in a clinic acceptable to the Council. With the infra-red unit, the distance for comfort on the average skin was found to be 24 inches. At 18 inches the heat was intolerable. The Council believes that the lamp will render satisfactory service to a physician who desires to practice infra-red radiation therapy.

The firm gives the following values:

	Spectral Range Angstrom Units	Dominant in Region of (Angstrom Units)	Wattage
Incandescent bulb	4 000-25 000	9 000-11 000	500 watts
Infra red unit	7 600-150 000	20 000-30 000	600 watts

The Victor Model "B" Thermo-Spectral Lamp, therefore, is placed on the Council's list of accepted devices.

HANOVIA GROUP IRRADIATION LAMP ACCEPTABLE

The Hanovia Chemical and Manufacturing Company offers for sale to the profession the following four models of group irradiation lamps:

- No 2135 A four burner unit for alternating current (60 or 25 cycles)
- No 2133 A two burner unit for alternating current (60 or 25 cycles)
- No 2134 A four burner unit for direct current 220 volts
- No 2132 A two-burner unit for direct current 220 volts

Aside from the number of burners, the construction of these lamps is practically the same. The burners themselves are similar in type to those used in the Super Alpine Sun Lamp which has been accepted by the Council on Physical Therapy and reported on in *THE JOURNAL*, July 30 1932 page 389.

The burner consists of an evacuated tubular vessel constructed of transparent fused quartz containing mercury pools, which function as electrodes and supply mercury vapor for arc operation. The group irradiation unit itself is ordinarily mounted in the ceiling, hence a remote-controlled lighting arrangement is required. The burners are lighted by establishing a momentary contact between the enclosed mercury pools. This is accomplished, first, by tilting the burner in such a manner that the mercury flows from one end to the other, second, by restoring the burner to its normal level so that the mercury flows back to its original position. Lighting is accomplished in the alternating current lamp by a motor-operated tilting device and is controlled by the operator stationed at the control cabinet. Establishment of the arc automatically returns the burner to its proper position and stops the motor.

Hanovia Group Irradiation Lamp Acceptable

The physical and clinical claims in the descriptive literature and advertising matter for this unit conform with the Council's statement "Regulations to Govern Advertising of Ultraviolet Radiation Generators to the Medical Profession."

The Hanovia Group Irradiation Lamp, therefore, is included on the list of accepted devices for physical therapy.

EVEREADY SOLARIUM TYPE CARBON ARC LAMP REACCEPTED

In a report published in *THE JOURNAL*, Aug 22, 1931, page 541, the Council accepted for one year the Eveready Solarium Type Carbon Arc Lamp, manufactured by the National Carbon Company Inc., Cleveland. It is designed to administer therapeutic light treatment simultaneously to groups of patients.

The length of the lamp is approximately 3 feet and the width depends on the number of units included in each lamp. One, two or four units can be housed in a complete solarium lamp. Canopy, reflectors, exhaust fan and remote control cabinet are supplied with each unit. Suitable ammeters for measuring the current at each arc are supplied and placed in a convenient position on each control cabinet. Each unit is designed to accommodate two pairs of carbons. The arc burns between only one pair of carbons at a time. As these burn the arc shifts to the other pair without interruption. The carbons are brought into contact, separated and held at proper arc distance by means of a motor operated, constant current, arc control. The feeding of the arc is entirely automatic and the feeding mechanism is started merely by pushing a switch on the remote control cabinet. The carbons are drawn together and when the arc strikes they separate to the correct arc length. When the carbons have burned to the minimum permissible length, the arc is automatically extinguished. The firm claims that Eveready Carbons will operate the generator for ten hours without attention.

The standard therapeutic solarium unit is built for operation on 220 volt, 60 cycle alternating current, at 60 amperes arc current. The arc potential is approximately 50 volts and each arc requires an input of 3,100 watts at 205 amperes line current.

The claims made for this lamp in the advertising matter examined by the Council comply with the published statement "Regulations to Govern Advertising of Ultraviolet Generators to the Medical Profession." The Eveready Solarium Type Carbon Arc Lamp, therefore, is accepted and included in the accepted list of devices for physical therapy for the regular period of three years.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

NEO-SYNEPHRIN HYDROCHLORIDE—laevo α -hydroxy- β -methyl-amino-3-hydroxy ethylbenzene hydrochloride.—The hydrochloride of the laevo isomer of a synthetically prepared derivative of phenylethylamine having the formula $C_6H_5OH \cdot CHOHCH \cdot NHCH_2 \cdot HCl$. Neo-synephrin hydrochloride differs from synephrin tartrate in that (1) neo-synephrin hydrochloride is a salt of hydrochloric acid—synephrin tartrate is a salt of tartaric acid, (2) neo-synephrin hydrochloride is a laevo compound—synephrin tartrate is a dextro compound, and (3) the hydroxyl of the nucleus in neo-synephrin hydrochloride is in the *meta* position—in synephrin tartrate it is in the *para* position.

Actions and Uses—Neo-synephrin hydrochloride is a vasoconstrictor which is active when administered orally. It is more powerful in vasoconstrictive ability than synephrin tartrate, and possesses a relatively low toxicity. Applied to mucous membranes it causes contraction of the small blood vessels, thus reducing swelling and congestion of such membranes. Neo-synephrin hydrochloride may be useful in the symptomatic treatment of the nasal congestion accompanying disorders of the upper respiratory tract such as sinusitis, vasomotor rhinitis and hay fever. It may also be employed in combination with a local anesthetic, for surgical or dental use.

Dosage—For topical application to the nasal mucous membrane the 0.25 per cent solution is ordinarily used. The 1 per cent solution, diluted with an equal volume of physiologic solution of sodium chloride or Ringer's solution, may be used when a stronger preparation is desired. For surgical and dental anesthesia, it may be diluted in the proportion of three to four drops of the 1 per cent solution to 10 cc of a 2 per cent procaine hydrochloride solution. Neo-synephrin hydrochloride is relatively stable in alkaline solutions, it may be sterilized by boiling.

Manufactured by Frederick Stearns & Company, Detroit. U. S. patent 1,680,055 (Aug. 7, 1928; expires 1945). U. S. trademark 90,142.

Solution Neo-Synephrin Hydrochloride 0.25 Per Cent—Neo-synephrin hydrochloride 0.25 per cent, sodium benzoate 0.1 per cent, and sodium chloride 0.8 per cent, in distilled water.

Solution Neo-Synephrin Hydrochloride 1 Per Cent—Neo-synephrin hydrochloride 1 per cent, sodium benzoate 0.1 per cent, and sodium chloride 0.8 per cent, in distilled water.

Neo-synephrin hydrochloride occurs as white odorless nonhygroscopic crystals possessing a bitter taste. It is readily soluble in water and alcohol. The aqueous solution is neutral to litmus paper. It melts between 139-141°C. The specific rotation $[\alpha]_D^{25}$ ranges between -46.2 and -47.2.

Transfer 0.3 Gm of neo-synephrin hydrochloride to a glass container, dissolve in 3 cc of water, add 15 drops of ammonia water and rub the glass container with a glass rod the base that separates when washed with cold water and dried melts at 170-171°C without decomposition. Determine the nitrogen content of the base by the micro Dumas method; the nitrogen found is not less than 8.2 per cent nor more than 8.5 per cent. Dissolve 0.010 Gm of neo-synephrin hydrochloride in 1 cc of water and add 1 cc of copper sulphate solution (10 per cent) followed by 1 cc of sodium hydroxide solution (20 per cent); a reddish purple color forms that is not extracted by ether. Dissolve 0.01 Gm of neo-synephrin hydrochloride in 1 cc of water and add 1 drop of ferric chloride (10 per cent); a permanent amethyst purple color develops. Dissolve 0.02 Gm of neo-synephrin hydrochloride in 3 cc of alcoholic potassium hydroxide solution, add 3 drops of chloroform and boil; there is no odor of carbamine (absence of primary amines). Dissolve 0.05 Gm of neo-synephrin hydrochloride in 30-40 cc of distilled water, add 1 cc of diluted hydrochloric acid in

1 cc of barium chloride solution; no turbidity should result (absence of sulphate). Dissolve 0.2 Gm of neo-synephrin hydrochloride in 10 cc of distilled water; the solution yields a negative test for heavy metals when tested according to the U. S. P. X method (see U. S. P. X, page 439). To 1 cc of a solution containing 0.02 Gm of neo-synephrin hydrochloride add 2 drops of a freshly prepared solution of sodium nitroprusside 1 per cent, then 1 cc of sodium hydroxide solution followed by 0.6 cc (10 drops) of glacial acetic acid; the final solution should not be a deeper yellow than the same reagents without the neo-synephrin hydrochloride (absence of corresponding ketone).

Dissolve about 0.2 Gm of neo-synephrin hydrochloride accurately weighed in 200 cc of water, heat to boiling, add 4 cc of diluted nitric acid, followed by silver nitrate solution in slight excess, allow the container and mixture to stand for six hours; transfer to a Gooch crucible, wash well with diluted nitric acid (10 cc of diluted nitric acid diluted to 100 cc), dry at 100°C, cool in a desiccator and weigh the chloride (Cl^-) calculated from the silver chloride weighed is not less than 17.20 per cent nor more than 17.60 per cent. Heat about 0.2 Gm of neo-synephrin hydrochloride accurately weighed for twenty-four hours in an oven at 100°C; the loss is not more than 0.1 per cent. Determine the nitrogen content by the micro Dumas method; the nitrogen found is not less than 6.7 per cent nor more than 7.0 per cent. Transfer about 0.5 Gm of neo-synephrin hydrochloride accurately weighed to a platinum dish, ignite until constant weight is attained; the ash is less than 0.1 per cent.

Neo-Synephrin Hydrochloride 1 Per Cent Solution

Transfer 10 cc of the solution to a beaker, evaporate the solution to dryness on a boiling water bath, extract the residue with three 15 cc portions of boiling absolute isopropyl alcohol, evaporate the isopropyl alcohol to dryness on a boiling water bath, dry the extract in an oven at 100°C to constant weight; the residue is equal to not less than 0.95 per cent nor more than 1.05 per cent. The melting point ranges between 138 and 140°C.

Dissolve the residue in 3 cc of water, add 10 drops of ammonia water, rub the glass container with a glass rod, filter the precipitate, wash with cold water on a porous plate; the melting point is 169-171°C.

Neo-Synephrin Hydrochloride 1/4 Per Cent Solution

Follow the standards as described for the 1 per cent solution except use a 25 cc sample.

DILAUDID—Dihydro-morphine hydrochloride— $C_{17}H_{19}O_3 \cdot N \cdot HCl$. Dilaudid differs essentially from morphine hydrochloride in that one of the hydroxyl groups of the latter has been replaced by a ketone group.

Actions and Uses—Dilaudid is closely allied both chemically and pharmacologically to morphine, having the analgesic property of morphine as well as its action on the respiratory system. Its action on the intestine is probably less marked than is that of morphine. It is more toxic than morphine and is clinically effective in doses which are considerably smaller than are necessary with that alkaloid. It has been shown experimentally and clinically that dilaudid is powerfully analgesic and that, like morphine, it can depress the respiratory mechanism profoundly. At the same time, the experimentally established ratio between effective doses of morphine and dilaudid for the production of desirable effects is not materially different from the ratio between their toxic doses. Clinical trial has not shown that dilaudid is free from tolerance and addiction evoking properties, and, while side actions such as nausea, vomiting and constipation seem to occur less frequently than with morphine, the prolonged administration of dilaudid should be undertaken with as much caution as would be exercised with morphine itself. Dilaudid comes within the scope of the federal narcotic regulations.

Dosage—As a sedative and for the relief of pain, the usual oral dose is 2.5 mg ($\frac{1}{80}$ grain) in mild pain or cough, 13 mg ($\frac{1}{8}$ grain) may be given orally. The customary hypodermic dose is 2 mg ($\frac{1}{32}$ grain). Clinically the dose of dilaudid necessary to produce analgesia is about one-fifth that of morphine.

Manufactured by E. Bilbuer, Inc., Jersey City, N. J. (Bilbuer Knoll Corporation, Jersey City, N. J., distributor). No U. S. patent. German patent 380,919 (1923). U. S. trademark 298,197.

Ampules Solution Dilaudid 2 mg ($\frac{1}{32}$ grain) 11 cc. Each cubic centimeter contains dilaudid 2 mg, in physiologic solution of sodium chloride.

Hypodermic Tablets Dilaudid 2 mg ($\frac{1}{32}$ grain)

Hypodermic Tablets Dilaudid 3.2 mg ($\frac{1}{10}$ grain)

Hypodermic Tablets Dilaudid 4 mg ($\frac{1}{8}$ grain)

Tablets Dilaudid 2.5 mg ($\frac{1}{16}$ grain)

Dilaudid occurs as a fine white crystalline, odorless powder freely soluble in water, about 1 in 3, soluble in alcohol, insoluble in ether. Its aqueous solution is neutral to litmus. From aqueous solution ammonia water and sodium hydroxide precipitate the free base dihydromorphine as fine white crystals soluble in an excess of sodium hydroxide.

Dissolve about 0.5 Gm of dilaudid in 25 cc of water, add sufficient ammonia water to make distinctly alkaline and let stand overnight; collect the precipitate of dihydromorphine on a filter paper, wash with cold water, dry at 100°C; it melts with decomposition at 257 to 262°C. To 10 cc of the foregoing filtrate add an excess of diluted nitric acid and 2 cc of silver nitrate solution; a curdy white precipitate results soluble in an excess of ammonia water. Add 0.5 Gm of dilaudid previously dissolved in 2 cc of water to an aqueous solution containing 1 Gm of hydroxylamine hydrochloride, warm followed by the addition of an excess of ammonia water and set aside overnight; collect the precipitate of oxime on a filter paper, wash with a diluted ammonia water (1 part ammonia water with 99 parts of water) and water, dry at 100°C; it melts with decomposition at 230 to 235°C.

Dissolve 0.02 Gm of dilaudid in 5 cc of sulphuric acid and add 1 drop of ferric chloride solution and heat gently no blue coloration results. Dissolve 0.01 Gm of dilaudid in 1 cc of water and mix 10 cc of a freshly prepared potassium ferricyanide solution to which previously has been added 0.1 cc of ferric chloride solution a blue color results (*difference from codeine*). Boil about 0.2 Gm of dilaudid with 5 cc of sodium hydroxide solution the odor of ammonia is not noticeable (*ammonium salts*). Dissolve about 0.5 Gm of dilaudid in 15 cc of water separate portions of 5 cc each yield no red coloration on dilution with an equal volume of diluted hydrochloric acid and 0.2 cc of ferric chloride solution (*meconate*) no turbidity with 1 cc of diluted hydrochloric acid and 1 cc of barium chloride solution (*sulphate*) no coloration or precipitation on saturation with hydrogen sulphide (*salts of heavy metals*).

Dry about 0.5 Gm of dilaudid at 100 C for six hours the loss in weight does not exceed 15 per cent. Incinerate about 0.5 Gm of dilaudid accurately weighed the residue is not more than 0.1 per cent. Transfer about 0.3 Gm of dilaudid accurately weighed to a suitable Kjeldahl flask and determine the nitrogen content according to the official method described in Official and Tentative Methods of Analysis of the Association of Official Agricultural Chemists third edition page 20 chapter 2 paragraph 22 the percentage of nitrogen corresponds to not less than 4.25 per cent nor more than 4.5 per cent when calculated to the dried substance. Transfer about 0.3 Gm of dilaudid accurately weighed to a suitable beaker add 100 cc of water followed by the addition of 25 cc of silver nitrate solution and 10 cc of nitric acid boil with continuous stirring and allow to cool in a dark place. Collect the precipitate of silver chloride on a Gooch crucible wash with a diluted nitric acid and water followed by alcohol and ether finally dry to constant weight at 100 C the amount of hydrogen chloride calculated from the silver chloride found corresponds to not less than 11.25 per cent nor more than 11.5 per cent when calculated to the dried substance.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ADDITION TO THE RULES AND REGULATIONS

RAYMOND HERTWIG Secretary

SPECIAL PURPOSE FOODS

"Special Purpose Foods" with usefulness restricted to specific purposes such as inclusion in diets for obesity or morbid conditions, shall display on the labels and in the advertising in easily legible type and in close proximity to the trade name the designation 'Special Purpose Food' and a statement listing all ingredients in the order of their decreasing proportions by weight in the food.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

IRRADIATED VITAMIN D PASTEURIZED MILK

- (1) CLOVER LEAF DAIRY COMPANY S
- (2) DETROIT CREAMERY COMPANY S
- (3) EBLING CREAMERY COMPANY S
- (4) H P HOOD & SONS, INC
- (5) THE MITCHELL DAIRY COMPANY INC
- (6) OHIO CLOVER LEAF DAIRY COMPANY S
- (7) PRODUCERS MILK COMPANY S
- (8) QUALITY MILK PRODUCTS COMPANY S SELECT
- (9) QUALITY MILK PRODUCTS COMPANY S JERSEY
- (10) ROSZELL'S
- (11) SIDNEY WANZER & SONS, INC
- (12) ST LOUIS DAIRY COMPANY S

Distributors—(1) Clover Leaf Dairy Company Gary Ind, (2) Detroit Creamery Company, Detroit, (3) Ebling Creamery Company Detroit (4) H P Hood & Sons Inc, Boston, (5) The Mitchell Dairy Company, Inc., Bridgeport Conn (6) Ohio Clover Leaf Dairy Company, Toledo, Ohio, (7) The Producers Milk Company, Cleveland (8) and (9) Quality Milk Products Company Tulsa Okla (10) J D Roszell Company Peoria, Ill, (11) Sidney Wanzer & Sons, Inc, Chicago (12) St Louis Dairy Company St Louis

Description—Bottled pasteurized vitamin D milk irradiated with ultraviolet rays (patent No 1 680 818)

Preparation—The milk complies with legal requirements and is pasteurized by the standard holding method. For description of irradiation, see THE JOURNAL, Oct 7, 1933, page 1155

Vitamins—Clinical investigation shows this milk to be a reliable antirachitic agent if proper amount is used. Contains 135 U S P X (Revised, 1934) vitamin D units per quart.

Claims of Distributors—Irradiated antirachitic pasteurized milk having otherwise the flavor and food values of usual pasteurized milk.

SAVOY STRAINED VEGETABLES FOR INFANTS BEETS, CARROTS, GREEN BEANS, PEAS, PRUNES FLAVORED WITH LEMON JUICE, SPINACH, AND STRAINED VEGETABLES WITH CEREAL AND BEEF BROTH

UNSEASONED

Distributor—Steele-Weddes Company, Chicago

Packer—The Larsen Company, Green Bay, Wis

Description—Respectively sieved beets, carrots, green beans, peas, prunes flavored with lemon juice, spinach and vegetables (carrots, potatoes, tomatoes, celery, peas, beans, spinach) with pearl barley and beef extract prepared by efficient methods for retention in high degree of the natural mineral and vitamin values. No added sugar or salt. These products are the same as the respective accepted Larsen's vegetables and fruits (THE JOURNAL, July 8, 1933, p 125, July 22, 1933, p 282, July 29, 1933, p 366, Aug 12, 1933, p 525, Aug 19, 1933, p 605, Aug 26, 1933, p 675)

SUNKIST CAKE FLOUR

BLEACHED

Distributor—Maney Milling Co, Omaha

Manufacturer—Philip H Postel Milling Co, Mascoutah, Ill

Description—Soft winter wheat short patent flour, bleached

Manufacture—Soft winter wheat is washed, tempered and milled by essentially the same procedures as described in THE JOURNAL June 18, 1932, page 2210. Chosen flour streams are blended and bleached with nitrogen trichloride (4 Gm per barrel)

WINTERS PURINA 100% WHOLE WHEAT BREAD

Manufacturer—Southern California Baking Company, San Diego, Calif

Description—A whole wheat bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932 p 817) prepared from whole wheat flour, water, sweetened condensed skim milk, invert sugar, lard, sucrose, yeast, salt, malt syrup, and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

Analysis (submitted by manufacturer) —

	per cent
Moisture (entire loaf)	37.7
Ash	0.8
Fat (ether extraction method)	2.0
Protein (N X 6.25)	10.1
Crude fiber	1.2
Carbohydrates other than crude fiber (by difference)	48.2

Calories—25 per gram 71 per ounce

Claims of Manufacturer—Conforms to the United States Department of Agriculture definition and standard for whole wheat bread

ARMOUR'S STERILIZED UNSWEETENED EVAPORATED MILK

Manufacturer—Armour and Company, Chicago

Description—Unsweetered sterilized evaporated milk

Manufacture—The procedure of evaporation and canning, and the analysis are essentially the same as for the usual evaporated milk (THE JOURNAL, April 16 1932 p 1367)

Claims of Manufacturer—See announcement on the advertising of the Evaporated Milk Association (THE JOURNAL, Dec 19, 1931, p 1890)

PLASMA MAGNESIUM

Until recently, consideration of the physiologic role of the mineral nutrients tended to be overshadowed by an enthusiastic interest in certain organic factors potent in nutrition, namely, the vitamins. There is a rapidly growing tendency at present, however, to consider the possible relations of inorganic elements to the bodily functions. Surprisingly enough, this trend has been directed into the field of the nutritional significance of some mineral elements that occur as traces in the organism.¹ Thus, fluorine, aluminum, zinc, copper and manganese have been added to a list that has long included iron and iodine. One might assume from all this that the part played by the more familiar constituents, notably calcium, magnesium, sodium, potassium, chlorine and phosphorus, was now adequately understood.

This is certainly not the case for some of these elements. The significance of magnesium, for example, has remained vague indeed, despite the fact that its occurrence in notable amounts in both the blood and the body tissues has long been recognized. Most textbooks of biochemistry present at best a vague story of magnesium in the body. One writer,² who may be selected as representative, records that magnesium occurs in small amounts in all animal and plant cells. In vertebrates the body's chief store is in bone. Bone contains but one-eighth as much magnesium as calcium, muscle and nerve tissues, on the other hand, contain twice as much. The blood content is 3 mg per hundred cubic centimeters. Magnesium deficiencies do not occur on the average diet. Human milk contains little, indicating, he concludes, that but little is required, even by the growing organism.

Salts of magnesium have perhaps been better understood as pharmacologic agents. The use of magnesium sulphate (epsom salt) and of magnesium citrate as laxatives has a long and respectable tradition. Con-

siderable investigation has been devoted in the past to the explanation of the laxative effects. Soluble magnesium compounds have also become known, particularly through the studies of the late S. J. Meltzer, as substances that can induce narcosis when they are introduced in adequate doses parenterally into the body. How important magnesium may be in the routine of the physiologic processes has been made clear by McCollum and his co-workers³ at Johns Hopkins University. When experimental animals are restricted to a diet containing less than two parts per million of magnesium, they fail to grow and quickly become abnormal. Within three days all exposed skin areas show vasodilatation, which becomes intensified until about the tenth day. During this time the animals are nervous and easily startled, and by the end of the period (eleventh day) they may be so unstable as to go into convulsions in response to any disturbance, with fatal results in 80 per cent of the cases. There is loss of hair on the ears, jaws and neck, and the salivary and tear glands are hyperactive. After two or three weeks of magnesium deprivation, the teeth are affected and later the tissues around the teeth. Finally there is decalcification of the entire skeleton.

This is of course an extreme illustration, but it presents the possibility that cases showing convulsions or other conditions of increased neuromuscular activity would be encountered clinically in which the plasma magnesium is low. According to studies of Hirschfelder⁴ of the University of Minnesota, both hypomagnesemia and hypermagnesemia are clinical entities. The normal or average concentration of magnesium in the blood in health is about 2 mg per hundred cubic centimeters of the plasma, ranging from 1.8 to 2.5 mg. When healthy persons take epsom salt by mouth they excrete about 40 per cent of the ingested magnesium in the urine in twenty-four hours, but the concentration of magnesium in the blood plasma does not rise appreciably. However, when the kidneys are injured, administration of one or more purgative doses of epsom salt may lead to hypermagnesemia with its expected consequences. At a level of 11 mg of magnesium per hundred cubic centimeters, plasma drowsiness is likely to occur, a content of 17 mg was attended by coma.

Hirschfelder believes, from his clinical observations and blood chemistry studies, that many cases of coma in nephritic patients, diagnosed uremic coma, may be simply magnesium coma induced by epsom salt purgation. He remarks that since a single ordinary dose of epsom salt by mouth can raise the concentration of magnesium in the blood of nephritic patients to two thirds of the concentration at which coma sets in, and since with larger doses it is easy to induce coma in

¹ An interesting review of this subject is given by Rose Mary S. The Nutritional Significance of Some Mineral Elements Occurring as Traces in the Animal Body. Yale J. Biol. & Med. Mendel Anniversary Number 4: 499 (March) 1932.
² Cameron A. T. A Textbook of Biochemistry. New York: Macmillan Company 1933.

⁴ Hirschfelder A. D. Clinical Manifestations of High and Low Plasma Magnesium. J. A. M. A. 102: 1138 (April 7) 1934.

nephritic animals, it seems probable that a few repeated doses of epsom salt would induce coma in the patients. It is therefore most probable that there are every year in the United States many cases of coma occurring in nephritic patients which are diagnosed uremic coma but which in reality are magnesium coma caused by the use of epsom salt as a purgative. Since experimental animals could be brought out of this coma instantly and their lives prolonged by the intravenous injection of calcium chloride, the intravenous injection of calcium chloride would probably restore such patients to consciousness. The story of epsom salt probably applies comparably to magnesium citrate. Hirschfelder has also described a clinical syndrome associated with low plasma magnesium accompanied by a condition of hyperirritability of the neuromuscular system, often associated with muscular twitchings or convulsions. These cases are probably more common than has been realized. At least in the patient whose kidneys are pathologic the twitchings or convulsions can be relieved by the administration of a purgative dose of epsom salt by mouth. Apparently new chapters in the history of magnesium in the body are being written.

THE FUEL FOR STRENUOUS EXERCISE

The problem of the source of energy in vigorous muscular work has become increasingly complicated as new methods of investigation have been applied. The fuel of exercise may be investigated by analyses of the inspired and expired air during and after work. Information may also be obtained by studies of the change in composition of the blood and urine produced by the exercise. These studies have shown that sugars are the principal but not the only fuel used. There is no depletion of sugar as a result of short periods of strenuous exercise,¹ and no good effects can be expected from its administration. The fact that sugar is used in large amounts during muscular exercise does not indicate that the carbohydrate should be increased in the diet of athletes. The body is able to form sufficient sugar from any adequate diet except during prolonged violent exertion. In the latter case the carbohydrate reserve may be reduced to low levels.

The available observations on the blood sugar levels in exercise seem to be extremely contradictory. A partial explanation, at least, has been found in the degree to which excitement or emotional factors enter into the situation. During severe exercise in the laboratory, little variation is ordinarily observed. This steadiness is not equally true on the football field. Edwards, Richards and Dill² of the Fatigue Laboratory at Harvard University have observed that hyperglycemia is uncommon in exercise with little or no emotional stress but common in exercise with emotional stress

on the football field. In football players it is not much influenced by age within the range of 16 to 22 years, by diet, or by the mass of spectators. Before the game begins blood sugar is normal, and it appears to reach a peak when the game is half over. At the end of the game blood sugar may be normal while urine sugar is high, indicating that blood sugar has passed through a maximum. Inferentially, if exercise should continue (as in marathon races) hypoglycemia might result.

In the latest observations by Edwards, Margaria and Dill³ there is no evidence that carbohydrate is essential for strenuous exercise or that it is more essential in work than in rest. A study was made of exercise of sufficient duration and intensity to reduce the carbohydrate reserve to low levels. Altering the rate of work each half hour alters the proportion of energy derived from carbohydrate but not the blood sugar. With a plethora of carbohydrate some fat is used in exercise and, as carbohydrate reserve diminishes, the proportion of energy derived from fat may increase from 8 per cent to 77 per cent in actual cases. The Harvard physiologists believe that, while the choice of fuel is determined with precision, blood sugar concentration is not the governor. Thus, when dextrose is ingested during work and after depletion of carbohydrate reserves, the blood sugar may reach a maximum before there is a response of the respiratory quotient. It has often been assumed that the principal cause of fatigue is carbohydrate depletion. According to the Harvard investigations in man the accumulation of acetone bodies in exercise of long duration without food may be a primary source of breakdown.

MATERNAL MORTALITY

The United States Children's Bureau of the Department of Labor, with the assistance of an obstetric advisory committee, has presented an analytic report¹ of maternal deaths that occurred in thirteen states in 1927 and in the same states and two others in 1928. The states contributing the material for the study are fairly well distributed geographically and are typical of the sections in which they are located. In these fifteen states during the years of the study the deaths of 7,537 women were assigned to puerperal causes by the United States Bureau of Census. This number constituted 26 per cent of the deaths from puerperal sepsis in the entire birth registration area for these two years. In this study, 18 per cent of the deaths were of Negro women, with a rate nearly twice that for white women. The maternal mortality rate was 64 per 10,000 live births, as compared with a rate of 67 per 10,000 in the birth registration area for these two years. Of the total number studied it was found as

¹ Maternal Mortality in Fifteen States. Children's Bureau, Department of Labor, Bureau Publication 223. Maternal Deaths. Children's Bureau, Department of Labor, Bureau Publication 221 (abstract of complete report).

a result of interviews that 7,380 deaths had been actually puerperal in the meaning of the international classification, the detailed analyses are therefore based on these figures

Nine per cent of all the deaths were of women who had had no medical care or care only when dying. Of the women included in the study, more than half were hospitalized some time during their final illness. The deaths of 4,066 occurred in hospitals, but the deliveries or abortions of only 2,629 occurred in hospitals. Relatively few of these patients who died in hospitals had planned hospitalization. About one third of the women died before they reached the last trimester of pregnancy. For more than half the women who died in hospitals after reaching the last trimester, hospitalization was an emergency measure. Of these women, 83 per cent were attended by physicians, interns or medical students, 11 per cent by midwives and 4 per cent by nonmedical attendants, 2 per cent of the women had no attendant at the delivery or at death if the patient died undelivered. Puerperal septicemia was the most important cause of death prior to the seventh month and accounted for 59 per cent of the deaths in this period. The deaths of 509 unmarried women were included in the study. Approximately one half of the deaths in this group as compared with 39 per cent of the deaths of married women were from puerperal septicemia. The maternal mortality rate in the states included in the study (except one) was 143 per 10,000 illegitimate live births and 60 per 10,000 legitimate live births.

An attempt was made to estimate the quality of prenatal care by grading this care in three groups. Of the 1,478 women who first consulted the physician before or during the fifth month of pregnancy, 49 per cent received grade I care, 16 per cent grade II care and 34 per cent grade III care.

More than half of the women had had some operative procedure before death. In 26 per cent of the deaths following forceps deliveries and 19 per cent of the deaths following versions the fatal outcome was assigned to sepsis. Seven per cent of the deaths included in the study followed cesarean section. The advisory committee comments on this fact as follows: "The fact that cesarean section was done on one fourth of all the women who died following operation for delivery suggests that there had been unwise selection of cases for the operation—as cesarean sections constitute only a small percentage of all operative deliveries in general."

Abortion as used in this study may be defined as the termination of a previable uterine pregnancy. Puerperal septicemia was the cause of the deaths of 73 per cent of the 1,825 women who died following abortions. These deaths constituted 45 per cent of the total number of deaths from puerperal septicemia in this study. Puerperal septicemia accounted for 40 per cent of the 7,380 deaths included in the study. Thirty

per cent of all the deaths were preceded by some presumably toxic condition as the chief cause or chief contributory cause. The great majority of toxic deaths were of women who lacked some or all of the ordinary safeguards.

As a result of these studies, which should be read in full by all those dealing with any aspect of pregnancy, the advisory committee made certain recommendations to the medical profession and the public. Physicians should assume leadership in maternal care, should obtain more accurate information relative to the cause and prevention of maternal deaths, and should evolve methods for acquiring better and more up-to-date knowledge of the fundamentals of obstetric care. Widespread education of the public as to the importance of securing and dangers of not securing adequate obstetric care also is recommended.

Current Comment

FACTORS INFLUENCING THE DEXTROSE TOLERANCE TEST

The dextrose tolerance test is of importance in diagnosis and investigation, yet the results obtained are frequently of little significance because of inadequate control of various factors. Studies in this field have made increasingly evident the fact that carbohydrate tolerance tests on the same individual, conducted at different times, may yield widely divergent results. An interesting analysis of some of the causes of these variations has been reported by Malmros¹ from the clinic of internal medicine at the University of Lund, Sweden. This investigator has studied the effect of previous diet, of age, and of renal threshold on the results obtained from dextrose tolerance tests on non-diabetic patients in the university clinic. The observations with respect to previous diet are of particular interest, since they involve the relation of acidosis to carbohydrate tolerance, a relationship recently considered in these columns.² Malmros reports that a low carbohydrate diet preceding a dextrose tolerance test produced an acidosis in most cases studied, and these persons exhibited a decreased carbohydrate tolerance. However, the acidosis is apparently not the sole factor responsible for this result. Although ingestion of ammonium chloride did produce a considerable acidosis and a somewhat diminished tolerance to dextrose, in harmony with observations of other investigators,³ Malmros observed that a hypersensitiveness to carbohydrate could be shown also in instances in which no acidosis was present or in which the acidosis due to previous low carbohydrate ingestion was compensated by the administration of sodium bicarbonate. In fact, the carbohydrate tolerance after the ingestion of 20 Gm of ammonium chloride daily for four days appeared to be better than that observed following a period of restricted carbohydrate intake. This interesting hyper-

¹ Malmros, Hagvin. *Acta med. Scandinav.* supp. xxvii, 1928.

² Acid-Base Balance and Carbohydrate Tolerance, editorial, *J. A. M. A.* 102:620 (Feb. 24) 1934.

sensitiveness to carbohydrate after a regimen poor in carbohydrate and protein and rich in fat, appeared in patients as early as one day after the diet had been begun and was fully pronounced after three days, it remained for a short time after the subject was returned to an ordinary mixed diet. On the other hand, previous high carbohydrate feeding did not affect the dextrose tolerance test. These results are of considerable interest from a practical point of view. It appears that a dextrose tolerance determination following a low carbohydrate diet may yield a blood sugar curve resembling perfectly a diabetes curve in the absence of this disease. Not infrequently, persons in whom glycosuria has been demonstrated have been given limited amounts of carbohydrate, a subsequent tolerance test might readily result in a wrong diagnosis and unpleasant consequences for the patient.

Association News

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45 Central daylight saving time. The next three broadcasts will be as follows:

June 21 Mischiefous Misconceptions W. W. Bauer M.D.
June 28 Motor Touring and Camping, W. W. Bauer M.D.
July 5 Death Angel W. W. Bauer M.D.

National Broadcasting Company

The National Broadcasting Company talks have been discontinued for the summer.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Plague Infected Squirrels—Seven plague-infected ground squirrels were found in Tulare County, near Fountain Springs, May 9, according to *Public Health Reports*.

Society News—Dr. Frederick G. Novy, among others, addressed the Alameda County Medical Association, May 21 on "Lymphogranuloma Inguinale."—Dr. Noel F. Shambaugh, Long Beach, addressed the San Diego County Medical Society, June 12, on "Degenerative Liver Diseases."

Outbreak of Acute Anterior Poliomyelitis—The California State Department of Public Health recently reported a steadily mounting incidence of acute anterior poliomyelitis. Statistics on the incidence of this disease during January, February, March, April and the first four weeks of May of 1934 shows that 269 cases were reported. Analysis of the age groupings in the group of cases reported in May indicates that approximately 83 per cent of the patients are under the age of 15 years (from 1 to 4 years, 28 per cent; from 5 to 9 years, 38 per cent; from 10 to 14 years, 17 per cent) but the impression is had also that cases reported during the fifth week involve the older age groups. As is well known, this disease manifests itself ordinarily in the late summer and fall and increased incidence in the early summer is generally accepted as an epidemiologic indication that the disease will reach epidemic proportions. It is interesting to note that about 70 per cent of the cases were reported from the counties of southern California including Riverside, Orange, San Bernardino, San Diego and Los Angeles. If the same sequence of events should

occur in 1934 as did in 1930, the disease will undoubtedly spread throughout California. Under such conditions it is necessary that physicians scrutinize with "a high index of suspicion" any illness particularly of the respiratory or digestive tracts in individuals from the infected areas especially, for the probable incidental paralysis may not occur in many cases.

CONNECTICUT

State Laboratories Move—The bureau of laboratories of the Connecticut State Health Department, Hartford, moved from 247 Pearl Street, June 10, to new quarters in the Atlas Building.

State Medical Election—Dr. Walter R. Steiner, Hartford, was elected president of the Connecticut State Medical Society at its annual meeting, May 24, and Dr. Charles W. Comfort Jr., New Haven, was reelected secretary. The next annual session will be held in New Haven, May 22-23, 1935. In addition to various clinics, the scientific program consisted of the following:

Spondylolisthesis Dr. Robert G. Reynolds, Hartford
Concerning Certain Contacts Between Law and Medicine Dr. Daniel P. Griffin, Bridgeport
Treatment of Chronic Endocervicitis Dr. Edward J. Tracey, Norwalk
Lobar Pneumonia in Children: A Survey of Eighty-Six Cases Dr. Clifton C. Taylor, Bridgeport
Cancer of the Breast Dr. Douglas Quick, New York
Hyperparathyroidism Dr. Wilder Tileston, New Haven
Medical Aspects of the State Farm for Women Dr. Rose Howe, Jameson, Niantic
Use of Small Quantities of Radium in Malignancy of the Mouth, Uterus and Breast, Dr. George T. Pack, New York
Maternal Mortality in Connecticut Dr. Louis F. Middlebrook Jr., Hartford

Dr. Pack also conducted a symposium on cancer of the uterus. Dr. Eugene M. Blake, New Haven, opened a round table discussion on the diagnosis and treatment of paralytic squint. Dr. Dorland Smith, Bridgeport, one on treatment of chronic tear sac infections, and Dr. William T. Morrissey, New Britain, one on treatment of chronic ear infections. The Fairfield County Medical Association acted as host.

DISTRICT OF COLUMBIA

Medical Bills in Congress—H. R. 9836 introduced (by request) by Representative Lewis, Maryland, proposes to provide for the licensing of operators in beauty shops in the District of Columbia. The bill would apparently authorize cosmetologists to use electrical apparatus or appliances to remove superfluous hair, warts, or moles. S. 3479 has passed the Senate, proposing to amend the act regulating the practice of the healing art in the District of Columbia (1) by substituting the corporation counsel of the District of Columbia for the United States district attorney as a member of the Commission on Licensure to Practice the Healing Art, and (2) by transferring to the corporation counsel for the District of Columbia from the United States district attorney, the duty of instigating legal proceedings for the enforcement of the act.

FLORIDA

Society News—Dr. Nathaniel L. Spengler, Tampa, addressed the De Sota-Hardee-Highlands Counties Medical Society in Arcadia, April 10, on "Hyperthyroidism in Infants and Children."—Speakers before the quarterly meeting of the Leon-Gadsden-Liberty-Wakulla-Jefferson County Medical Society in Chattahoochee, April 19, included Drs. Robert B. McIver, Jacksonville, on "Surgical Notes on the Urinary Tract in Children," and William O. Martin Jr., Atlanta, "Management of Squint."—At a meeting of the Marion County Medical Society, April 12, Drs. Gerry R. Holden and Edward Jelks, Jacksonville, spoke on "The Physician's Responsibility in the Cancer Problem" and "Diagnosis of Malignant Conditions of the Intestinal Tract."

IDAHO

Society News—Dr. Edward L. Whitney, Walla Walla, Wash., discussed hypertension before the Nez Perce County Medical Society in Lewiston, March 21, and Dr. Carl J. Johannesson, Walla Walla, gave an illustrated address on "Cholecystography Correlated by Gastro-Intestinal X-Ray Examinations, Checked Against Surgical Findings."

Annual Registration Due July 1—All practitioners of medicine and surgery holding licenses to practice in Idaho are required by law to register annually on July 1 with the department of law enforcement and at that time to pay a fee of \$2. If a licensee has not paid the annual registration fee by October 1 his license can be cancelled and will be restored within five years thereafter on payment of the delinquent

fees and a \$10 penalty. If a license has been canceled for more than five years, it can be reinstated only on the payment of \$25 and on the licensee's passing an examination, the nature of which shall be determined by the department of law enforcement.

ILLINOIS

Society News—Dr William H. Olmsted, St. Louis, addressed a joint meeting of the Belleville and East St. Louis Medical Society and the St. Clair County Medical Society, June 7, on "Insulin Reaction in Treatment of Diabetes."

Chicago

Dr Slaymaker Honored—Dr Samuel R. Slaymaker, president of the Washington Boulevard Hospital and clinical professor of medicine, Rush Medical College, was guest of honor at a dinner given by 100 friends and colleagues at the University Club, June 7, in recognition of his twenty years' service with the hospital. An oil portrait of the guest of honor was presented to the hospital, and Dr Slaymaker was presented with a watch and chain. Dr Vincent J. O'Connor was toastmaster. Among the speakers were Dr Arthur R. Metz and Dr James B. Herrick. Photographs of the portrait were given to each one in attendance.

Ricketts Prize Awarded—The Division of Medical Sciences of the University of Chicago announces the award of the Howard Taylor Ricketts Prize for 1934 to Dr Paul E. Steiner and Thomas C. Grubb, Ph.D. Dr Steiner was given recognition for his work on "The Role of the Avian Tubercle Bacillus in the Etiology of Hodgkin's Disease" and Dr Grubb for his work on "Studies on the Coccus Forms of *Corynebacterium Diphtheriae*." The first award of this prize was made in 1913 to Dr Esmond R. Long and the late Dr George L. Kite. The announcement of the 1934 award was made on May 3, the anniversary of Dr Ricketts' death, which occurred while he was conducting research on typhus fever in Mexico.

Personal—Dr and Mrs Luther G. Bass observed their golden wedding anniversary April 22—Dr Grace Hiller, instructor in medicine in the Division of Medical Sciences, University of Chicago, has been appointed director of the student health service at Goucher College in Baltimore effective in the autumn—An illuminated parchment award of merit was presented to Matthew O. Foley, editorial director of *Hospital Management* by the trustees of the American Hospital Association. Dr Bert W. Caldwell, executive secretary of the association, made the presentation and speakers included Lewis Bernays, British consul; Dr Malcolm L. Harris, Dr Thomas Hugh Scott Hines, III, and Mr Asa S. Bacon, superintendent, Presbyterian Hospital. Mr Paul H. Fesler, superintendent, Wesley Memorial Hospital, was toastmaster.

INDIANA

Society News—Dr Robert B. Osgood, Boston, addressed the Terre Haute Academy of Medicine, the Fifth District Medical Society, the Vigo County Medical Society and the Aesculapian Society in Terre Haute, May 4, on "General Aspects of Arthritis and Its Treatment."—The Eleventh Indiana Councilor District Medical Association was addressed, May 16, in Kokomo, among others, by Dr Donald P. Abbott, Chicago, on "So-Called Indigestions—The Early Diagnosis of Gastro-Intestinal Disorders and Their Treatment," and Arthur L. Harter, D.D.S., Kokomo, "Dental and Medical Relationship."

Graduate Course—The Indiana University School of Medicine conducted a graduate course, May 21-June 2. Included on the program were Drs. Dean Lewis, professor of surgery, and Joseph C. Bloodgood, adjunct professor of surgery, Johns Hopkins University School of Medicine, Baltimore; Udo J. Wile, professor of dermatology and syphilology, University of Michigan Medical School, Ann Arbor; and Lester Dragstedt, Chicago. In addition to discussions of preventive medicine, early diagnosis and treatment of cancer and eradication and prevention of venereal diseases, a study of modern health problems as they relate to the professor of medicine as a whole was presented. A feature of the annual course was the alumni home-coming day and banquet with addresses among others, by Drs. Byrl R. Kirklin, class of 1914, head of the department of roentgenology of the Mayo Clinic; and Dr William T. Green, class of 1925, in orthopedic surgery, Harvard University Medical School, Boston. Their subjects were respectively, "Lesions of the Gastro-Intestinal Tract" and "Infections and Inflammations of the Bone."

IOWA

Summer Round Up—The summer round up of preschool children conducted each year by the Des Moines Council of Parent-Teacher Associations with the cooperation of local physicians has been assured. A special effort is being made to include in the free clinics only those children whose parents are unable to pay for the service.

Dr Thompson Honored—The Madison County Medical Society held a dinner for Dr William H. Thompson, Winter set, April 9, in recognition of his completion of fifty years in the practice of medicine. Dr Thompson was made an honorary member of the society. Dr Channing G. Smith, Granger, was toastmaster. Among those present were Drs. Walter L. Bierring, Des Moines, now President, American Medical Association, and Dr John H. Peck, former president of the National Tuberculosis Association.

MAINE

Medical Library—The Portland Medical Club recently established a medical reference library in the Portland Public Library, the nucleus of which was begun with voluntary contributions of members.

Typhoid Outbreak—Sixty-five cases and five deaths were reported in a recent outbreak of typhoid in Augusta. The disease was first diagnosed in a boy who had been ill for about ten days without medical attention, the father caring for him and also helping to milk the cows on the dairy farm. The milk was distributed to thirty-seven families and two grocery stores. Nurses and a physician were provided by the state department of health and more than 7,000 people were given antityphoid treatment at free clinics. An additional 1,500 persons were treated by private practitioners. All food handlers in the city, including milk dealers, were examined to locate possible carriers.

MARYLAND

Dohme Lectures—Donald D. Van Slyke, Ph.D., of the Rockefeller Institute for Medical Research, New York, delivered the Charles E. Dohme Memorial Lectures for 1934 at Johns Hopkins University School of Medicine, April 26-28. The lectures were entitled "Physiology of the Amino Acids" and "Factors Controlling Urea Excretion."

Dr Welch's Will Provides Endowment Fund—The needs of the Institute of History of Medicine and the Welch Medical Library will be given preference in the establishment of an endowment fund at Johns Hopkins University under the will of the late Dr. William H. Welch. After providing for the payment of several specific bequests, Dr. Welch left the residue of his estate in four parts, one of which is to establish the endowment fund for any purposes approved by the trustees, the institute and library to be given the preference. The university was also bequeathed all the physician's medical scientific and literary books, pamphlets, papers, medals and medical portraits, for the use of the medical school, including the Institute of the History of Medicine and the School of Hygiene and Public Health. Dr. Welch had been identified with Johns Hopkins University School of Medicine since 1884.

Society News—Dr George E. Bennett, Baltimore, gave an illustrated lecture before the Maryland Academy of Medicine and Surgery, April 17, on "Treatment of Fractures of the Neck of the Femur." Dr Arthur G. Barrett was installed as president of the society at this meeting, having been reelected to this position for the eighteenth time—Dr Hans Zinsser, Boston, addressed the Baltimore City Medical Society at its semiannual meeting, April 6, on "Variations of Typhus Fever."—Anna M. Baetjer, Sc.D., among others, addressed the seventh meeting of the Society of Hygiene of Johns Hopkins University, April 11, on "Relation of Potassium to the Contractions of the Mammalian Skeletal Muscle and Its Similarity to the Effect of Sympathetic Stimulation."—The Maryland Academy of Medicine and Surgery was addressed in Baltimore, May 15, by Dr Nathan B. Herman, among others, on "Diagnosis and Treatment of Hay Fever as Encountered in Maryland." Dr Lewis B. Hill, "Emotional Problems Expressed in Physical Symptoms" and Robert H. Brotman, D.D.S., "Dental Facts for the Physician."

MASSACHUSETTS

Departments Merged—The departments of botany, zoology and general physiology of the Biological Laboratories of Harvard University, Boston, have been consolidated to form a department of biology. Alfred C. Redfield, Ph.D., professor of physiology, has been appointed to the newly created position of director of the laboratories.

Society News—Dr Edward W Archibald, Montreal, addressed the semiannual meeting of the New England Medical Society in Boston May 31, on "Etiology and Treatment of Recurring Subacute Pancreatitis"—'Chronic Invalidism due to Joint Pathology' was discussed before the Massachusetts Society of Examining Physicians, May 23, by Drs Joel E Goldthwait, Howard K Thompson and Carl L Watson—The Hampden District Medical Society was addressed, April 24, by Dr Abraham Myerson, Boston, on "The Neuroses as the General Practitioner Meets Them" Dr Archibald J Douglas, Westfield, was elected president of the society

Expedition to Study Onchocerciasis—The continuation of investigations carried on by Dr Richard P Strong in Guatemala on the control and elimination of onchocerciasis and the development of scientific and medical knowledge of the Katanga region, are the objects of a six-months expedition which sailed, April 25, for Africa under the auspices of the department of tropical medicine The members include

Dr Richard P Strong director
Joseph C Bequaert Ph D entomologist
Jack H Sandground Sc D helminthologist
Mr Henry E Mallinckrodt laboratory assistant photographer
Mr R Stuyvesant Pierret Jr zoological assistant
Mr Byron L Bennett technician

MICHIGAN

Society News—Dr Walter G Maddock, Ann Arbor spoke before the Berrien and Cass County medical societies at Dowagiac, May 16, on "General Care of Peripheral Vascular Diseases"—The Houghton County Medical Society was addressed in Calumet, May 1, by Drs Alfred C LaBine, Houghton and George M Walde, Hancock, on "Thoracic Surgery in Tuberculosis"—Reuben L Kahn, D Sc, director of laboratories, University Hospitals, Ann Arbor, addressed the Oakland County Medical Society in Pontiac, May 16, on "Immunological Considerations in Connection with Vaccine Therapy" Dr Carl E Badgley, Ann Arbor, addressed the society, April 18, on lesions of the upper extremity—Dr Robert C Jamieson, Detroit was chosen president-elect of the Wayne County Medical Society at its annual session, May 21 Dr William J Cassidy was installed as president Alexander G Ruthven, president, University of Michigan, Ann Arbor, spoke among others, on "Modern Trends in Professional Education"

Physicians Honored—The regular alumni banquet of the Detroit College of Medicine and Surgery, now the Wayne University College of Medicine, June 7, served as a testimonial dinner to Drs Andrew P Biddle Don M Campbell and Angus McLean "three of the oldest and most useful graduates of the school" Dr James W Inches was toastmaster Dr Biddle, who has been professor emeritus of dermatology and syphilology at his alma mater since 1917, first became associated with the school in 1892 In addition to serving as secretary and counsellor to the state medical society Dr Biddle was president for two successive terms, from 1916 to 1918 Dr Campbell has been a member of the school's faculty for forty years, many of which have been as professor and head of the department of ophthalmology He was president of the Wayne County Medical Society from 1914 to 1915 Dr McLean was affiliated with his alma mater from 1905 to 1913 as professor of clinical surgery However, he has been more active in positions with the state and city governments, he served as city physician from 1888 to 1892 quarantine inspector for the Port of Detroit, 1893, became a member of the state board of health in 1905, and in 1911, a member of the Detroit Board of Health He is a past president of the Wayne County Medical Society and of the Michigan State Medical Society

MISSISSIPPI

State Medical Election—Dr James R Hill, Corinth, was chosen president-elect of the Mississippi State Medical Association at its annual meeting in Natchez May 10, and Dr Edward C Parker, Gulfport, was installed as president Vice presidents are Drs Altus B Harvey, Tylertown, Gilruth Darrington, Yazoo City, and Richard C Smith, Drew Blount was designated as the place for the next annual meeting, May 14-16, 1935

Medical School to Be Remodeled—An appropriation of \$75,000 by the state legislature makes possible the renovation of the old medical building of the University of Mississippi School of Medicine and also the remodeling of two floors of one of the wings of the University Hospital for the departments of physiology pathology and bacteriology It will also provide new equipment It is reported that the entrance

requirements will be raised from two to three years of college work and that the courses in physical diagnosis and clinical microscopy will be made adequate to meet the requirements of the four year schools

MISSOURI

Tuberculosis Day—Tuberculosis Day, the annual celebration of the Tuberculosis and Health Society, will be observed in St Louis June 26 A National League baseball game will be played at Sportsman's Park, following the entertainment

Society News—Speakers before the St Louis Medical Society, June 5, were Drs Bransford Lewis and Major G Seelig on 'Vocations and Avocations for the Doctor' and "History and Significance of Quackery in Medicine," respectively The society devoted its meeting, May 29, to the memory of members who had died since June, 1932

NEW JERSEY

Personal—Eugene Maier, Ph D, formerly of the staff of the Rockefeller Institute for Medical Research and of the department of pathology, Bellevue Hospital, New York, has been appointed chief bacteriologist of the Merck Institute for Therapeutic Research, Rahway—Dr Frank Overton, Patchogue, N Y, has been appointed editor of the *New Jersey Medical Journal*

State Medical Election—Dr Marcus W Newcomb, Browns Mills, was chosen president-elect of the Medical Society of New Jersey at its annual meeting in Atlantic City, June 6 Dr Lancelot Ely, Somerville, was installed as president Vice presidents are Drs Francis R Haussling, Newark, and Spencer T Snedecor, Hackensack Dr John Bennett Morrison, Newark, is secretary, and Dr Elias J Marsh, Paterson, treasurer

NEW YORK

Osteopaths Barred from Practicing Surgery—A bill designed to permit osteopaths to practice surgery with certain limitations was vetoed, May 23, by Governor Lehman According to the *New York Times*, the governor said

This bill eliminates the present requirement of the Education Law that an osteopath shall not perform surgery with the use of instruments and adds a number of provisions which seem to authorize osteopaths to engage in every form of medical practice except the giving of drugs by mouth to cure disease and the performance of certain specified surgical operations

It was further stated that, because of the ambiguous wording of the bill, it would be impossible to restrict and prevent any type of medical practice other than some types of major surgery

Health at Schenectady—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended June 2, indicate that the highest mortality rate (248) appears for Schenectady and for the group of cities as a whole, 112 The mortality rate for Schenectady for the corresponding week last year was 86 and for the group of cities, 10 The annual rate for eighty-six cities for the twenty-two weeks of 1934 was 123 as against a rate of 117 for the corresponding period of the previous year Caution should be used in the interpretation of these weekly figures, as they fluctuate widely The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate

New York City

Golden Anniversary Dinner—Eight physicians who have held membership in the Medical Society of the County of Kings for fifty years or more were guests of honor at a dinner given by the society at the Hotel St George, May 24 They were Drs William Browning, Frank E West John C MacEvitt, Lewis S Pilcher, Elias H Bartley, Charles P Gildersleeve, William Moitrier and John A Cochran Dr Dean Lewis, Baltimore, President, American Medical Association, was guest speaker The Medical Society of Kings County is 112 years old

Memorial Hospital Fifty Years Old—A dinner celebrating the fiftieth anniversary of Memorial Hospital for the Treatment of Cancer and Allied Diseases was held, May 25 at the Waldorf-Astoria Speakers were Dr James Ewing, chairman of the medical board Dr Edward C Dodds, director, the Courtauld Institute, Middlesex Hospital, London, England, Dr Livingston Farrand president of Cornell University, Mrs Robert G Mead, chairman of the finance committee, New York City Cancer Committee, and Dr George H Bigelow, superintendent of Massachusetts General Hospital and former

health commissioner of Massachusetts, Boston. At a special scientific meeting, May 24 at the New York Academy of Medicine, Dr John A. Hartwell spoke on "The Place of a Cancer Institute in Medical Organization", Dr Robert B. Greenough, Boston, on "Organization of Cancer Service in General Hospitals", Clarence C. Little, Sc D, Bar Harbor, Maine, "Heredity in Cancer," and Dr Dodds, "Cancerogenic Agents."

Society News—Dr Fred Wise addressed the American Stomatological Association, May 15, on "Buccal and Labial Lesions of Interest to Dentist and General Practitioner."—Dr Henry A. Rafsky addressed the Medical Society of the County of Queens, April 20, on diagnosis and treatment of gallbladder disease. Dr Abraham M. Rabiner spoke, May 4, on sciatica. Dr Augustus L. Harris addressed the society, May 29, on uroscopy, and Dr George L. Brodhead, maternal mortality.—Dr John H. Morris addressed the New York Surgical Society, May 9 on "Cholesterosis of the Gallbladder."—Dr Marie Pichel Levinson addressed the North Bronx Medical Society, April 5, on "Dangers of Gold Stem Pessaries."—Dr George W. Holmes, Boston, addressed the New York Roentgen Society, May 21, on "Roentgen Diagnosis of Obscure Lesions in the Upper Gastro-Intestinal Tract."—Dr Leila Charlton Knox, among others addressed the New York Pathological Society, May 24, on "Synoviomata: Report of Three Cases."

NORTH CAROLINA

State Medical Election—Dr Paul P. McCam, Sanatorium was installed as president of the Medical Society of North Carolina at its annual meeting, May 2. Dr Paul H. Runger, Asheville, was chosen president elect and Dr Lewis B. McBrayer, Southern Pines, reelected secretary. The next annual session will be held at Pinehurst, May 6-8, 1935.

New Health Department—The commissioners have approved the establishment of a full-time health department for Bertie County, effective July 1. Dr Frank H. Garriss, Lewiston, has been named county health officer. The county discontinued its health department four years ago. The new unit will be financed in part by the state board of health.

OHIO

Society News—Dr Henry B. Freiberg, Cincinnati spoke on "Prostatic Resection" before the Clinton County Medical Society in Wilmington, May 1.—At a meeting of the Warren County Medical Society at Lebanon May 1, Dr Leo S. Friedman, Cincinnati, discussed communicable diseases.—Speakers before the Greene County Medical Society May 3, were Drs Jerome Hartman and Herbert L. Brumbaugh, Dayton, on osteomyelitis and orthopedic causes of pain in the back, respectively.—Dr Arthur O. Peters, health commissioner of Dayton discussed the New Set Up in Medicine from a Public Health Standpoint" before the Montgomery County Medical Society, May 18.—At a meeting of the Logan County Medical Society, Dr Clarence A. Mills, Cincinnati, spoke on "Climate and Weather as Health Factors."—Speakers before the Wood County Medical Society, April 19, were Drs Bernhard Steinberg and J. Lester Kobacher, Toledo, on "Pathology of the Heart, Lungs and Kidneys as Concerns the General Practitioner" and "Modern Clinical and Laboratory Features of Cardiac Diagnosis," respectively.—Dr Hugh G. Beatty, Columbus considered "Sinus Infection in Children and Its Relation to Lower Respiratory Infections" before the Ashland County Medical Society, May 11.—A special meeting of the Portage County Medical Society in Ravenna, May 3, was addressed by Dr Louis J. Karnosh, Cleveland, on "Insanities of the World's Great Geniuses."—Dr Arthur S. Jones, Huntington, W. Va., discussed "Peripheral Nerve Injuries" before the Washington County Medical Society at Marietta May 9.—At a meeting of the Hempstead Academy of Medicine May 14, Dr George M. Curtis, Columbus, discussed "The Significance of Iodine in the Management of Toxic Goiter."

PENNSYLVANIA

Alumni Day Clinics—The University of Pittsburgh School of Medicine held its first annual day of clinics for the alumni and their guests June 2. At a luncheon following the clinics Dr Ralph H. Boots, New York, gave an address on arthritis.

Cancer Meeting—A public meeting on cancer constituted the meeting of the Cambria and Somerset County medical societies in Johnstown May 10. Speakers were Drs Joseph C. Bloodgood, Baltimore; Bernard P. Widmann, Philadelphia, and Samuel J. Waterworth, Clearfield.

Society News—The annual meeting of the Sixth Council District of the Medical Society of the State of Pennsylvania was held at State College, May 24. In addition to reports the program included addresses by Drs John O. Bower, Philadelphia, on "The Physician's Duty to the Public in the Appendicitis Campaign" and Harold A. Miller, Pittsburgh, "Present and Future Medical Relief in Pennsylvania." Dr Samuel P. Glover, Altoona, was the guest of honor at luncheon in recognition of his completion of fifty years of practice.—Dr Joseph A. Hepp, Pittsburgh, addressed the McKeesport Academy of Medicine, May 28, on gynecologic endocrinology.

Philadelphia

Fund to Study Convulsions—The Viola J. Lowe Memorial Research Fund has been established at the Temple University School of Medicine, it was announced May 20, by Samuel E. Lowe, president of the Whitman Publishing Company, Racine, Wis. The fund will finance the study of convulsions occurring in epilepsy and other diseases having convulsive manifestations. The work will be conducted under the direction of Drs Temple S. Fay, Frank W. Konzelmann and Omer William Wheeler.

University News—The Leffmann Biological Assay Research Laboratory at the Philadelphia College of Pharmacy and Science, named in honor of the late Dr Henry Leffmann, was dedicated, May 11. Dr Leffmann was at one time professor of general chemistry, toxicology and hygiene at the Woman's Medical College of Philadelphia, professor of clinical chemistry and hygiene, Graduate School of Medicine of the University of Pennsylvania and lecturer on research at the college of pharmacy. He died in 1930.—Surg. Gen. Hugh S. Cumming, U. S. Public Health Service, Washington, D. C., gave the commencement address of Woman's Medical College of Pennsylvania, June 6.

Portrait of Dr. Babcock—A portrait of Dr. William Wayne Babcock, for thirty-one years professor of surgery at Temple University Medical School, was presented to the school May 2 by the classes of 1933 and 1934. Dr. George W. Crile, Cleveland, delivered the principal address. Tributes were paid to Dr. Babcock by Drs. Herbert L. Northrop, Edward J. Klopp and Thomas A. Shallow. Dr. Donald W. Ingham, Lancaster, president of the class of 1933, and John William Crosson, president of the class of 1934, made the presentation and Charles E. Beury, LL.D., accepted the portrait on behalf of the university. Dr. Babcock is at present president of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons.

VIRGINIA

Society News—At a meeting of the University of Virginia Medical Society, May 7, Dr. Eugene M. K. Geising, Baltimore, talked on recent studies of the function of the posterior lobe hormone.

Graduate Clinic at University Hospital—The thirteenth graduate clinic at the University of Virginia Hospital, University, in cooperation with the department of clinical education of the Medical Society of Virginia, was held May 17. Subjects of clinics were emergency treatment of fractures, tumors and problem children. Addresses were made by Drs. Kenneth F. Marx, on public health phases of communicable diseases, William W. Waddell, Jr., treatment of communicable diseases, Oscar Swineford, Jr., management of hay fever and James C. Flippin, the physician and advances in medicine.

WASHINGTON

Society News—Physicians of Okanogan County recently organized a county medical society at a meeting in Omak with Dr. James Fred Mills, Omak, as president and Dr. Lorenzo S. Dewey, Omak, secretary.—Dr. John F. Leocog, Seattle, addressed the Kitsap County Medical Society, Bremerton, April 10, on fractures of the leg.—Dr. Howard L. Hull, Elma, addressed the Pierce County Medical Society, Lakeview, April 10, on "The Mantoux Test and Its Interpretation."—Dr. John F. Beatty, Everett, addressed the Snohomish County Medical Society, Everett, April 3, on heart failure.—Dr. Richard F. Berg, Portland, was the speaker before the Spokane County Medical Society, Spokane, April 12, on "Injuries to the Knee Joint."—Drs. Donald V. Trueblood and Brien T. King, Seattle, discussed neoplastic diseases and hyperparathyroidism respectively before the Whatcom County Medical Society, Bellingham, April 2.—At a meeting of the Yakima County Medical Society, Yakima, April 9, Drs. Lester J. Palmer and Maurice F. Dwyer, Seattle, delivered addresses on "Liver Functions in Glucose Metabolism" and "Roentgen-

ology of the Chest," respectively—Dr. Park Weed Willis, Seattle, addressed the King County Medical Society, May 7, on "The Doctor on the Witness Stand"—Drs. Homer J. Davidson and Charles Homer Wheeler, Seattle, addressed the Chelan County Medical Society, April 13, on "Treatment of Mucous Colitis" and "Low Blood Sugar," respectively

GENERAL

Study of Congenitally Malformed Children—The Gynecological Hospital Institute of Gynecologic Research of the University of Pennsylvania, Philadelphia, is conducting an intensive study of families into which congenitally malformed children have been born. Special interest centers in families in which malformations have appeared in two or more children. The objectives of the study are to determine the nature of recurrence in the same family, to study the nature of the defects and to possibly throw light on their etiology. Physicians who have knowledge of any such families are urged to communicate with Dr. Douglas P. Murphy at the institute.

Prize for Essay on Industrial Medicine—The sixth International Congress on Industrial Accidents and Diseases announces a prize of 1,000 Swiss francs to the author of the best (unpublished) original work on the subject "The Importance of Previous Physical Condition in Estimating the Sequelae of an Industrial Accident." Physicians in all countries are invited to take part. Manuscripts must be in hand by December 31. The award will be made during the next congress to be held in Brussels in July 1935. Those interested should communicate with Dr. Fred H. Albee, 57 West Fifty-Seventh Street, New York, or Dr. Emery R. Hayhurst, Ohio State Health Department, Columbus.

Regulations for Practice in Switzerland—Recent changes in regulations governing entrance to examination for the practice of medicine in Switzerland have restricted eligibility to Swiss citizens, the U. S. Treasury Department has been informed. However, a treaty may be made with any state that admits Swiss physicians to practice within its borders. The federal council also reserves the right to authorize taking of the examinations in "extraordinary cases" and "in consideration of particular circumstances." Foreign medical students who at the time the decree was promulgated were registered in a Swiss university, on the basis of a school graduation certificate conferring the right to admission to the examinations for the practice of medicine, are exempt from these changes.

Medical Study Trip to Hungary—American physicians of good standing are invited to join a study trip to Hungary, which is being arranged by a committee of New York physicians at the invitation of the Hungarian Medical Postgraduate Committee of Budapest. The party will sail from New York August 18, visiting Munich and Oberammergau en route. The return trip may be made optionally via Berlin, Paris or Italy, arriving in New York September 30. Dr. Harlow Brooks is chairman of the committee and Dr. Richard Kovacs, secretary. Other members are Drs. Charles G. Kerley, Jerome M. Lynch, Wendell C. Phillips and Ervin Torok, all of New York. Dr. Emile de Grosz is president of the Hungarian Medical Postgraduate Committee of Budapest.

Health Projects in CWA Program—A total of 75,763 men were employed in health projects during the existence of the Civil Works Administration. The estimated total cost was \$12,242,886. In the improvement of sanitary conditions in rural communities, 32,010 men were employed at a cost of about \$5,000,000. Malaria control, consisting of the elimination of mosquito breeding places, occupied 29,779 men at an estimated cost of \$4,500,000. Similarly typhus fever control was pursued with 7,033 men at a cost of \$1,143,636. The U. S. Public Health Service directed most of these services, the last in cooperation with the Bureau of Biological Survey and in addition directed the work of sealing abandoned coal mines to prevent chemical reactions which have been making treatment of drinking water difficult. The Bureau of Entomology also employed 369 men in spotted fever control work which consisted of clearing and burning undergrowth in areas where ticks are abundant. The cost of this project was \$79,500.

Medical Bills in Congress—*Changes in Status*. S. 1286 has passed the Senate, providing that for the purposes of promotion, longevity pay and retirement there shall be credited to officers of the Veterinary Corps and former officers of the Veterinary Corps now on the retired list all full-time service rendered by them as veterinarians in the Quartermaster Department, Cavalry or Field Artillery. S. 527 has passed the Senate, directing the Secretary of the Treasury to pay to Lillian Morden the sum of \$2462.20 in full settlement of all claims against the Government for medical expenses incurred

as a result of contracting influenza while employed as a student nurse in the Medical Department of the Army at Fort Dodge, Des Moines, Iowa, and providing that Lillian Morden shall be admitted to such army hospital as may be directed by the Surgeon General of the United States Army for necessary care and treatment. S. 2892 has passed the Senate, amending existing laws prohibiting the introduction of intoxicating liquors within the Indian country to permit their use as medicine by practicing physicians for patients of Indian blood. H. R. 3768 has passed the Senate, changing the name of the retail liquor dealers' stamp tax in the case of retail drug stores or pharmacies to "medicinal spirits stamp tax." S. 2800, the Copeland food and drug bill, has been reprinted to include various amendments submitted by Senator Copeland, on behalf of the Senate Committee on Commerce, June 8.

ALASKA

Personal—Dr. Walter W. Council, Juneau, has been appointed secretary-treasurer of the Alaska Board of Medical Examiners. He is also territorial commissioner of health.

Government Services

Health of the Army

The general death rate in the United States Army during 1933 was 41 per thousand of strength, as computed from weekly reports to the surgeon general. The rate for 1932 was 42 and for 1931 it was 45. The admission rate was 612 per thousand, as compared with 668 for 1932. The rate would have been still lower, the report points out, had it not been for an epidemic of respiratory diseases which carried over from the latter part of 1932 into January 1933. The total respiratory group accounted for an admission rate of 148 per thousand, as compared with 205 for 1932. Venereal diseases caused an admission rate of 30, a new low point. In the Civilian Conservation Corps, which was in existence for thirty-nine of the fifty-two weeks of 1933, the admission rate for diseases and injuries was 198 per thousand. There were 425 deaths during the period, a rate of 2.5. Respiratory diseases caused a rate of 248. During the year there were fifty-four cases of typhoid, twenty-eight in one company at Hamilton, Texas. Twenty-eight cases of meningitis occurred. Some of the rarer causes of admission to sick report were tetanus, 1, tick fever, 1, undulant fever, 1, encephalitis, 3, poliomyelitis, 11, and smallpox, 4.

Death of Former Chief of Biological Survey

Edward William Nelson, who was chief of the Bureau of Biological Survey of the U. S. Department of Agriculture from 1916 to 1927, died of heart disease in Washington, May 19, aged 79. Since his retirement as chief he had been engaged in research. He held the honorary degrees of M. A. from Yale University and Sc. D. from George Washington University, both conferred in 1920. His published work includes monographs on mammals and birds and descriptions of many new species.

Applications of Interns in U. S. Public Health Service

The U. S. Public Health Service will consider applications to fill a number of vacancies which exist at the present time and also vacancies which will occur about July 1, for second year medical interns. Any young physicians, not over 30 years of age, who have graduated from class "A" medical colleges and who have completed, or will shortly complete, one year's internship in approved hospitals are eligible to apply. The public health service desires to secure applications only from candidates who are interested in the service as a career and who desire to request permission to appear before a board of commissioned officers for examination for appointment as assistant surgeons in the regular commissioned corps, on or about the time they will complete a year's service as interns in the public health service. Applicants who are selected will be offered appointments with quarters, subsistence and laundry, and \$86.50 per month until June 30, when the cash pay will be increased to \$93.25, net, per month. Those interested in making application should address inquiries to the Surgeon General, U. S. Public Health Service, Washington, D. C., and more complete information and the necessary blanks on which to make application will be furnished.

LONDON

(From Our Regular Correspondent)

May 19, 1934

A Further Increase of Road Accidents

A serious increase of road accidents during the first three months of this year, compared with the corresponding period of last year, is reported. In Great Britain, excluding London, there was an increase of 1375 per cent in the number of persons killed and 125 in those injured. In Scotland there was an increase of 565 per cent in the number killed and 1075 in those injured. A rise in the number of deaths in Glasgow from 24 to 45 and in Edinburgh from 9 to 22 mainly accounted for the increased percentage in Scotland. In Wales the increase in the number killed was 33 per cent. Commenting on these figures, Lieut.-Col. Jocelyn Pickard, secretary of the National Safety First Association (formed to prevent road accidents), said that there were 105,000 more automobiles on the road than last year, which might partially account for the increase of accidents. In London there was an increase in the number of accidents but a slight decrease in the number of deaths. The injured in the first three months of this year numbered 12,263, against 11,078 in the same period of last year. The total number of accidents was 32,138 and 27,009, respectively.

The Minimum Food Requirements

The controversy aroused by the publication of two somewhat divergent reports on minimum dietetic requirements was reported in *THE JOURNAL*, February 10, page 469. The main difference was that the committee of the Ministry of Health estimated 3,000 calories and 37 Gm of first class protein as the daily requirements of a man doing moderate physical work, while the corresponding figures of the committee of the British Medical Association were 3,400 calories and 50 Gm of protein. The committee of the British Medical Association set out to determine the minimum weekly expenditure on foodstuffs which must be incurred by families of varying size if health and working capacity are to be maintained, and to construct specimen diets. The fact that the ministry accepted the advice of its own committee became the grounds for a political attack on the government, charging that the physicians of the British Medical Association had been flouted in a matter on which the lives of 2,000,000 unemployed persons depended. The difference has been investigated by a conference, which included Sir F. G. Hopkins, Professor Cathcart and Professor Mellanby representing the ministry's committee and Professor Cowell, Professor Mottram and Dr. G. P. Crowden representing the committee of the British Medical Association. The difference was found to be more a matter of misinterpretation than of actual fact. The ministry's committee was a permanent body appointed to advise on the practical application of modern advances in the knowledge of nutrition. It consisted of workers with a special knowledge of nutrition who did not possess authority to act or advise in economic matters. Their recommendation regarding requirements of calories and protein was intended to serve as a rough guide to health officers and to assist them in placing on a proper basis the nutrition of the communities and institutions under their charge. The values being statistical averages, were meant to apply to whole communities and not to individuals or single families. On the other hand, the committee of the British Medical Association was not a permanent body but a special one assembled for a specific purpose. Its task was partly financial, and it had to decide on the food allowances necessary to maintain health and working capacity. It had to bear in mind that the unemployed

spent much time in working on allotments, going to labor exchanges, or keeping themselves in good condition by exercising daily at training centers. They therefore recommended the 3,400 calories and 50 Gm of first class protein per "man equivalent."

The conference emphasizes the fact that there does not exist a standard of food requirements that can be rigidly applied in the same manner to all men and suggests that a sliding scale of caloric requirements is needed. It recommends the following

Requirements per Day

Individuals	Calories Gross
Man heavy work	3 400-4 000
Man moderate work	3 000 3 400
Man light work	2 600 3 000
Woman active work	2 800 3 000
Woman housewife	2 600 2 800
Boy 14-18	3 000 3 400
Girl 14-18	2 800 3 000
Child 12-14	2 800 3 000
Child 10-12	2 300 2 800
Child 8-10	2 000 2 300
Child 6-8	1 700 2 000
Child 3-6	1 400 1 700
Child 2-3	1 100 1 400
Child 1-2	900 1 100

The conference also agreed that the average requirements of the entire population or of large mixed groups of people is about 3,000 calories a day, but for individual requirements the sliding scale should be consulted.

PROTEINS AND VITAMINS

Accumulated evidence indicated that the total daily requirement of protein per man probably lay between 80 and 100 Gm. The amount depended on physique, occupation, habits, personal taste and age, while climate appeared to be a factor of some importance. There was general agreement that a certain proportion of the total protein should be in the form of first class protein, i. e., of animal origin, such as milk, eggs, cheese, meat and fish. However, the desirable proportion of animal to total protein has never been determined. Growing children and expectant and nursing mothers required relatively large amounts of first class protein, much more than would be arrived at by simple calculation based on man value equivalents. All recent studies had shown that for children milk was a most valuable food. It was, indeed, the only known naturally balanced food containing not only first class protein (187 Gm to the pint) in readily available form but also minerals, vitamins, carbohydrate and fat. The conference therefore stressed the importance of this highly nutritious food for children and nursing and expectant mothers.

Fatal Accidents to Children

Fatal accidents to children were discussed at the congress of the National Safety First Association, held in London. Colonel Oakes said that the total number of accidents in 1932 was 3,718, of which 2,938 were in boys and 1,320 in girls—roughly, three boys to every two girls. Nearly 1,500 children were killed on the roads. More than one fifth, approximately 800, of the total casualties involved children under the age of 1 year. One third of the casualties, 1,200, or approximately 45 per cent, occurred during the next four years from burns and scalds, and 34 per cent in road accidents. Thus, more than 2,000, more than half the children killed in accidents, were under 5 years of age. More than 1,000 fatalities occurred in the next five years, and more than two thirds of these were on the roads. Only one sixth—namely, 600—occurred in the later school ages, from 10 to 14 years, and more than 50 per cent were on the roads. Eight times as many boys as girls were drowned. Twice as many girls as boys were victims of burns, whereas the number of boys who died from scalds was approximately twice as great as the number of girls.

With reference to the road accidents to children occurring in England and Wales, more than 900 out of 1,150 were to

pedestrians, 200 to pedal cyclists, and approximately 50 to passengers in vehicles. The number of pedestrian victims reached a maximum at the ages of 4 to 5 years. During the later school years the child became a relatively safe walker and at 15 was perhaps an example to many seniors. But at the same age he (not she) was nearing his worst record as a safe pedal cyclist. The research of the association showed 16 as the most dangerous age for pedal cyclists, 15 coming next. The great majority of casualties were in boys.

The Undiminished Maternal Mortality

At a dinner held in support of the Safer Motherhood Campaign, Mrs. Stanley Baldwin, the wife of the statesman who led a campaign to provide anesthesia for poor women in labor, presided. Sir Hilton Young, minister of health, said that recent investigation had shown that a large proportion of the deaths in childbirth were due to preventable causes. He therefore welcomed the assistance of voluntary organizations. Two lines of advance were possible: one was the education of the expectant mother in antenatal care, the other the development of those services which rendered assistance to the expectant mother. At present the government provided maternity benefit (a payment of \$7 to the wives under the national insurance act). There was a clear case for the development of those services provided by the local authorities on behalf of the mother and child, particularly in the supply and organization of midwives and arrangements for the services of consultants. He proposes to issue a circular on the subject to local authorities, pointing out the direction in which the development of their services was still required, particularly in those areas where the maternal mortality is highest. The condition that causes concern is the unsatisfactory fact that while general mortality and infantile mortality have greatly declined in recent years, maternal mortality remains undiminished.

PARIS

(From Our Regular Correspondent)

April 25, 1934

Treatment of Undulant Fever

Professor Lemierre of the Faculté de médecine de Paris delivered a lecture on the treatment of undulant fever which appears to be getting more prevalent. He prefers injections of microbic endoproteins derived from cultures of *Alcaligenes abortus*, which Reilly was the first to employ. Extraction of the endoproteins is done by the Besredka method. Three-day cultures on gelose are scraped, dried in vacuo and ground with 40 per cent of sodium chloride. An emulsion in distilled water is prepared in such a manner that 1 cc of fluid corresponds to 0.02 Gm of the dried culture. After being centrifugated, or set aside for twenty-four hours in the icebox, the supernatant fluid is collected, put in ampules and then sterilized. This preparation has a high antigenic value. It contains the endoproteins of 500 billion germs per cubic centimeter. In 1926 Courtois Suffit, Garnier and Liege applied this treatment successfully, although at the price of a severe reaction that kept the temperature at 40 C for three days. Lemierre regards this treatment as the most effective available for combating undulant fever but he emphasizes that antigen therapy acts exclusively on persons in a state of allergy as previously determined by a positive Burnet cutaneous reaction. If the test is negative, it is useless to employ this method. If a state of allergy is lacking, it can sometimes be created by repeating patiently the Burnet cutaneous test. Not until then can one apply antigen therapy which is always remarkably effective but less so when there are secondary, articular, osseous or pulmonary localizations. In the cases of *Alcaligenes melitensis* the method has given precisely the same results. The treatment should be regulated in the following manner. First one

applies the Burnet test by injecting into the skin 0.2 cc of an extract of *Alcaligenes melitensis* or of *Alcaligenes abortus* and one reads the result at the end of from eighteen to twenty-four hours. When positive, the diameter of the reddened and infiltrated area will vary from the diameter of a lentil to that of the palm of the hand. The dose of endoprotein that is then injected by the intramuscular route, or preferably by the subcutaneous route, to avoid local pain will range between 0.33 cc and 1.5 cc, the smaller doses being reserved for cases in which the skin reaction is strongest. From one and one-half to two hours later, a severe chill commonly develops, together with a temperature of 39, 40 or even 41 C (from 102.2 to 105.8 F). After from twenty-four to forty-eight hours, the temperature falls suddenly to about 36.5 C (97.7 F), often if, during the next few days, a new Burnet skin test is applied, it will then be found negative. In the presence of the very strong Burnet skin reaction, great caution must be taken to save the patient a serious shock. The minimal dose of endoprotein injected in such cases may be without effect. A second dose may be given two days later, the quantity of inoculated endoprotein being increased. Sometimes even a third dose must be given. In the cases in which the sensitivity of the organism is very marked, successive injections of gradually increased doses appear to be preferable. It is too early to speak of cures in these cases. In undulant fever, new waves of fever may develop after prolonged periods of apyrexia. Nevertheless, great improvement immediately follows the violent shock reaction, the amelioration being manifest in the temperature and in the general condition of the patient.

Radiographers Required to Be Doctors

A new law pertaining to the practice of medicine will require the possession of a doctor's diploma in order to practice radiography and radiotherapy. Heretofore the radiographic laboratories in the hospitals have been under the direction of specialists who are not graduate physicians. Their number was small, dating for the most part from the beginning period of the use of roentgen rays. Many of these men had adapted themselves to this work in a remarkable manner. Occasionally, however, examples of fraud in the form of "trick films," in connection with claims following occupational accidents, have been discovered. Physicians have for some time shown displeasure at the role assumed by nondiplomaed radiographers, whom they have charged with a lack of knowledge of anatomy and with not always knowing what part of the body merited particular attention for the establishment of a diagnosis. With regard to treatment, this constituted it was pointed out, the illegal practice of medicine and entailed serious risks for the patients. As the result of demands made by the medical syndicates, parliament inserted this regulation in the new law. Nondiplomaed hospital radiologists appointed more than thirty years ago, and who have won the respect of physicians by the meritorious quality of their services, are to be admitted to registration.

A New Museum of History and Art

Mr. Mourier, director of the Assistance publique, has created a special museum designed to house historical relics and art objects derived from hospitals, hospital chapels and offices of charitable organizations in Paris. The museum is located on the banks of the Seine, quai de la Tournelle, in the vast apartments of the old Hotel de Miramon erected in the seventeenth century by Mansard, and which served in 1691 as a convent. After 1792 the building was occupied by manufacturers of weapons. In 1810, Napoleon I turned over the property to the Assistance publique de Paris, which installed therein its central pharmacy. The latter gradually accumulated a collection of relics and art objects derived from razed or

remodeled hospitals, the preservation of which appeared to present some degree of interest. There is a collection of 740 crucibles and various types of pharmacist's equipment, including earthenware from Delft, Nevers, Rouen, Sceaux, St Cloud and Sinceny. Much of the material has an inestimable value. The construction of new pharmaceutical laboratories, with modern equipment, will vacate the six large halls of the ground floor, adorned with beautiful wainscoting of the Renaissance period, where the collection of pottery was supplemented by numerous art objects for which there seemed to be no place in the modern hospitals: paintings, sculptures, engravings, artistic furniture, placards, sketches and voluminous correspondence. There is a fine bust of the financier Baujon, by Houdon, a portrait of Madame de Stael, founder of the Hôpital Necker, by Duplessis, a portrait of St Vincent de Paul and the "dames de la charité" (seventeenth century). The fine pieces of furniture of the period of Louis XV, the Regency and Louis XVI are numerous. There is a collection of ironwork derived from chapels: mortars, pewters, shovels, locks, and wrought mantel-piece plaques. Among the choice old books is the "Livre de vie active," a parchment manuscript, with miniatures dating from 1483.

BERLIN

April 23, 1934

The German Surgical Congress

The Deutsche Gesellschaft für Chirurgie held its session in Berlin, April 5-7. Professor Kirschner of Heidelberg, the chairman, took up his reply to the memorial of the Deutsche Orthopädische Gesellschaft. He brought out that it will not do to turn over entirely to the orthopedists the surgery of the motor and the supporting systems, leaving to the surgeon the remainder of the body. For the orthopedist, the bloodless measures and those requiring apparatus should be in the forefront. The special test for orthopedists in the state examination is not feasible (*THE JOURNAL*, Sept 16, 1933, p 942). Olivecrona of Stockholm spoke on technic and results of surgical operation in tumors of the auditory nerve. As a pupil of Cushing, he stated that in America the mortality resulting from the application of the intracapsular enucleation method had been reduced to from 4 to 10 per cent. None of the patients, however, regain their full working capacity. Patients operated on die in from three to four years at the latest, as the result of recurrences. Olivecrona removes, after the enucleation of the tumor, also the so called capsule. The working capacity of the patients has since been considerably improved, the mortality, however, has increased to about 20 per cent. The cerebellar tumors observed in the Kiel clinic were 50 per cent inoperable by reason of their malignity (medulloblastomas, ependymomas). Traumatic and nontraumatic thickening of the dura, as Jentzer of Geneva brought out, may resemble brain tumors. A technic for ventriculography, suggested by Peiper of Frankfurt-on-Main, consists in introducing a cannula within a ventricle and a second within the spinal canal. As spinal fluid flows from the lumbar cannula, the ventricular cannula automatically draws in air. Of course this method is applicable only in case all the cerebrospinal fluid passages are fully open. For the regulation of the blood flow through the brain, Schneider of Breslau has found, by means of experimentation, reflexive processes that are evidently controlled by way of the meningeal media. Following epinephrine, glyceryl trinitrate and hypertonic solution of dextrose, better blood distribution occurs. Carbon dioxide does not suppress the blood flow through the brain. According to the experiences of the surgical clinic in Tübingen, spinal anesthesia is to be recommended for these operations, to which, as Kirschner himself

suggested, scopolamine may be added intravenously by the drip method in order to induce partial anesthesia.

K H Bauer of Breslau discussed the sterilization law in its relation to surgery. A responsibility rests on the surgeon with reference to congenital hereditary malformations and their operative removal, but he cannot influence the *massa hereditaria*. Hence, in the event that an injury of the *massa hereditaria* occurs, sterility must result, even though the external injury in the person so affected has been effectively repaired. At least one million persons in Germany come within the scope of the sterilization law. In the interpretation of the law a decisive role is assigned to the physician. The commentary on the law published by the government needs to be further elaborated in order that mild and severe injuries may be more sharply differentiated.

The next topic was "Therapy of Pyogenous Infections and of Their Sequelae." Every infection—even the slightest—is to be regarded as a disorder of the whole organism. In combating an infection not only must the local manifestations be treated but also the general defense forces of the organism must be strengthened. There are four phases of the treatment: strengthening of the general resistance; increase of the local defense; elimination of the disease foci by opening the wound; and, finally, the protection and immobilization of the organ concerned. For drainage, a proper incision must be promptly made without causing disturbances of function. In furuncles and carbuncles, injections of the patient's own blood into the surrounding area are recommended. Remedies having a strong chemical action that injures the tissues should not be employed. Incised wounds should be left alone, after being covered with a moist bandage or an ointment plaster. An incision with an electric knife is to be regarded as the most conservative mode of dividing the tissues in inflammations. Induced ischemia should be avoided from principle, in these operations. Infiltration anesthesia is rejected by Lexer. Fistulas should not be treated with injections and tamponades but, if in any wise possible, with broad cleavage. Lexer called special attention to the results if osteomyelitis is not promptly and adequately opened up. What holds good for acute inflammation of the soft parts is justified here also.

In recent injuries, burns and phlegmonous inflammations, Lohr of Magdeburg employs cod liver oil ointment. *Bacillus coli*, *staphylococci* and *streptococci* are destroyed in cod liver oil. He reported therefore on his plaster of paris cod liver oil method in the treatment of acute and chronic osteomyelitis. After the periosteum has been split, a large plug of cod liver oil is inserted, a loose soft-part suture is applied, and then a plaster cast, which is left on for from two to three weeks. Opportunity is offered for the pus to flow off from under the bandage. In chronic cases, radical opening of the bone is indicated, then application of the plug of cod liver oil ointment and a plaster cast. Some of the advantages claimed for the method are that no painful changing of bandages is needed, and no abscesses or fistulas develop.

Sauerbruch of Berlin spoke on the operative treatment of bronchiectasia. He emphasized that the unilobar appearance of this disease in children is to be regarded as congenital, contrary to the conception of most pediatricians who assumed inflammatory causes. This view of Sauerbruch was confirmed by numerous preparations of the Berlin Pathologisches Universitäts-Institut. The surgical treatment consists in the radical removal of the affected lobe of the lung, which is all the more to be recommended now that the operative technic is sufficiently developed and since internal treatment never effects a cure. Fifty-eight cases have been treated thus far. Six patients died following the operation, the survivors are able to work, although two have a fistula. Treatment of noncongenital bronchiectasias does not give such good results.

The next main topic, "Surgery of Rectal Cancer," was presented by Goetze of Erlangen, who stressed the importance of a rectal examination for a prompt diagnosis. The sacral operative method is to be preferred. Liver metastases cannot be diagnosed by means of liver function tests. In contrast with this operative method, the abdominal route is a menace. For all these interventions, the high frequency current is highly recommended. Goetze performed in a third of his cases a one stage, radical operation, with from 10 to 15 per cent of mortality. If the carcinoma is already causing intoxication some time before the operation proper an artificial anus should be constructed in the sigmoid. In addition, a diet poor in salt should be given, and the circulation should be supported in anticipation. A further third of all cases can be treated with a two or three stage operation. The remaining third cannot be subjected to a radical operation, in these cases, rectotomy in combination with coagulation was chiefly employed. Also roentgenotherapy can be used—but not alone. Kirschner of Heidelberg recommended his combined sacral and abdominal method, which is applied by two operators working simultaneously, with the patient in a position especially adapted to the operation. The advantage is a gain in time, together with the possibility of a particularly radical procedure, the mortality, however, is higher.

Lauen of Königsberg organized in East Prussia a voluntary systematic examination of the healthy population. First 1200 women who considered themselves healthy were examined for cancer of the breast. One grave cancer two suspicious cases and 103 cases of old chronic inflammations were discovered. Of ten women who had previously undergone an operation for cancer, eight were in good health.

Felix of Berlin reported that his experiments had shown that both paralyzed and hypertrophic muscles can be favorably influenced by certain types of nerve transplantation. It is possible that such experimentation will develop methods for the surgical treatment of disorders of the heart muscle.

In hypertrophy of the prostate, Wildegans of Berlin and Kraas of Frankfurt-on Main recommended diathermy operations by the intra-urethral route, usually requiring several stages. Hemorrhage can thereby be readily controlled. Even in aged and weakly patients, good results are secured.

In other papers, numerous fields of surgery were considered. Professor Magnus, who was recently given a chair at the University of Berlin, was elected president of the society.

ITALY

(From Our Regular Correspondent)

April 15 1934

Surgery of Gastroduodenal Ulcer

Laccetti addressed the Accademia delle scienze mediche-chirurgiche of Naples on the surgical treatment of gastroduodenal ulcer. He pointed out that, in the midst of uncertainty of the etiologic factor, there is a tendency to attack the ulcer directly or to eliminate it together with neighboring tissues. The speaker in a case of postoperative jejunal ulcer operated by the transgastric route, treating the ulcer with the thermocautery. The result was favorable. Laccetti believes that, while gastroenterostomy remains the preferred operation in the pyloric cicatricial type of ulcer, it can be omitted in duodenal ulcer and the Judd operation substituted.

Professor Cavina in discussing this intervention before the Accademia medico-fisica fiorentina, said that he endeavored to remove the local lesion, to destroy the muscular activity of the pylorus and to eliminate two of the principal symptoms of duodenal ulcer, namely, stasis and gastric hyperacidity. The Judd operation is indicated in young persons in ulcers of recent origin particularly of the anterior wall of the bulb, in cases in which the duodenum is fairly mobile and not too much

deformed. In seven cases in which Cavina operated recently there was an excellent immediate result, and the remote result proved to be fairly favorable.

Physicians Made Senators

Professors Pende and Micheli were recently made senators. Prof. Nicola Pende, born in 1880, was one of the organizers of the University of Bari (1924), became instructor in clinical medicine, and was the first to fill the office of president. In 1925 he took over the management of the Clinica medica in Genoa, where he founded an institute of biotypology. Among the researches of Pende may be mentioned demonstration of the secretory and trophic influence of the splanchnic nerves and the solar plexus on the suprarenal capsules and the proposal (suggested by Professor Pieri, surgeon) to resect the splanchnic nerve in patients with angiospasm due to hyper-suprarenalism. His chief works are "Pathology of the Sympathicus" (in collaboration with P. Castellino), "Treatise on Endocrinology" and "Synthetic Treatise on Pathology and Clinical Medicine."

Prof. Ferdinando Micheli was born in 1872. He became professor of pathology at Siena and at Florence and from 1921 was director of the Clinica medica at the University of Turin. The principal subjects of his researches have been pernicious anemia, hemolytic icterus, paroxysmal hemoglobinuria, epidemic encephalitis, the serology of malignant neoplasms, and leukemia. He contributed an article on pulmonary tuberculosis for the recently published Italian treatise on internal medicine. He is codirector of the medical journal *Minerva medica*.

The Medicosurgical Congress of Calabria

The second Medicosurgical Congress of Calabria was held in Reggio Calabria under the chairmanship of Prof. Rocco Jemma. A paper was presented by Salvadori on laryngeal tuberculosis. In a group of 814 patients with pulmonary tuberculosis, the speaker studied 148 patients with laryngeal tuberculosis. While recognizing tuberculous sputum as a frequent cause of laryngeal tuberculosis, recent research attributes importance to transmission by the blood stream or by the lymph glands. Tropea emphasized that the treatment of both the lungs and the larynx should be equally vigorous, and he assigned special importance to sanatorium treatment and to collapse therapy. He refuted the old prejudice that mountain climate is contraindicated in tuberculosis of the larynx. It is advisable to examine laryngoscopically all patients affected with pulmonary lesions.

Puca presented a paper on epilepsy. He said it is the whole organism, mental and somatic, that participates in the morbid process and not cyclically but continuously. He stated that in the regions having the greatest wine consumption there is the highest incidence of epilepsy.

Professor Stanziale

The death of Prof. Rodolfo Stanziale, director of the Clinica dermosifilopatica in Naples, is announced. A pupil of Professor Cantani, Professor Stanziale studied bacteriology at first and for twelve years devoted himself to pathologic anatomy and histology. During that period he published his important work (still a classic) on the changes produced by syphilis in the arteries and particularly in the brain. He devoted himself later to studies on cutaneous tuberculosis, the experimental transmission of leprosy from man to the rabbit and pemphigus vegetans (Neumann). He was appointed professor of the pathology and clinical aspects of dermatology and syphilis, first at Messina and then at Naples, and later published a book on the prophylaxis of the venereal diseases. He founded at Naples the Istituto fotoradioterapico and was awarded a medal for his services in public health. His constant study of leprosy

made him one of the foremost leprologists in the world, and he was chosen as the Italian delegate to the third International Conference on Leprosy, held in Paris

The Incidence of Mental Diseases

The Istituto centrale di statistica has published a report from which it appears that there is a gradual and continuous increase in the number of inmates of the Italian psychiatric hospitals. The incidence is highest in northern Italy (and among the male sex) and is the lowest in southern Italy. The most frequent types are the affective psychoses, and particularly the subgroup of the depressive and melancholic states. The frequency of alcoholic psychoses shows a slight decrease. The manifestations dependent on syphilitic infection are increasing, particularly as to the types of dementia paralytica. The mortality in this disease appears, however, to be diminished in direct relation with the use of febrile treatment.

RIO DE JANEIRO

April 15, 1934

Diagnosis of Thoracic Aneurysms

Dr Manoel de Abreu, roentgenologist, addressed the Society of Medicine and Surgery of São Paulo on thoracic aneurysms. The diagnosis of aneurysms of the thoracic aorta, he said, was previously based on the relations between the tumor as revealed by roentgenology and the aortic tube as outlined by teleroentgenography in various positions. Now "blood hydrodynamics" is considered fundamental in any consideration of thoracic aneurysm. In a liquid mass in movement, hydrodynamics explains the development of centrifugal forces such as occur at the curves of rivers, the convex or external borders of which are deeply excavated while the concave or internal borders are flat. In closed tubes, as in the aorta, the blood stream pushed on by the left ventricle exerts on the vascular wall forces that obey the principles of hydraulics and give to the aneurysmal pouches their morphology and direction. Consequently aneurysms of the beginning of the ascending aorta which are close to the heart are directed upward, to the right and forward; those of the terminal portion orient themselves upward; those of the transverse portion are directed in the horizontal plane; those of the descending portion go down. The weight of the aneurysmal mass deviates slightly from the direction of the axis of development of the mass. In general, one may say that the axis of development of aneurysms approximates a line that bisects the angle formed by the axis of the aortic segment and by the vertical line (gravity). Consequently the aortic segment in which the aneurysm forms determines the development of the sac and constitutes the basis of the differential diagnosis. One must not forget the changes due to the resistance of the bony breast plate, the vertebral column and the thoracic contents, principally the heart and the vessels of the hilus. The author discussed the practical use of the theoretical data given and showed teleroentgenographic plates of aneurysms of all segments of the thoracic aorta, of tumors and of other disorders of the chest.

Hospitals of Rio de Janeiro

The following hospitals are under construction:

The Hospital Jesus for children will have a capacity of 150 beds. It will also admit mothers whose infants are in the hospital. It will have equipment to give instruction to children who remain in the hospital a long time.

The 150 bed Hospital of Gavea will be in a locality accessible to the population of Gavea Leblon, part of Botafogo and Copacabana. The Hospital of the Avenue 28th of September, in Villa Isabel is more complete and larger than the others. It will have more clinics than have the other hospitals already

started and also complete physical therapeutic services, roentgen therapy, hydrotherapy, mechanotherapy, and so on. It will attend also to other dependent services of the township, such as school clinics and health inspection of municipal employees, until central laboratories are installed. Its consultation rooms are arranged in such a way as to allow an attendance of thirty patients at the same time without overcrowding. The construction of the Central Hospital, on the Place of the Republic is also well advanced. This hospital will accommodate 600 patients and have a teaching institute including a school for nurses and postgraduate courses, a library, conference rooms and museums, the municipal morgue for persons who have died in hotels or other public locations, and central laboratories of pathologic anatomy, of clinical investigation and of fabrication of medical products.

An Association of Physicians

The Paulist Association of Medicine has approved by a great majority the necessity of creating the Order of Physicians, as the basis of a program of vindication of the Brazil medical profession. The project includes compulsory organization of all physicians of the country and its complete autonomy. The order will represent medical practitioners before the public campaigning for the adoption of laws protecting their moral and material interests and for measures of repression of the illegal practice of medicine; it will create a disciplinary council to enforce the observance of the code and demand that physicians who have studied abroad be naturalized and take a complete medical course in one of the official faculties of the country. It will elect its officers by direct vote.

JAPAN

(From Our Regular Correspondent)

April 30, 1934

Night-Blindness in Soldiers

Dr Y Fujihira, ex-surgeon of the garrison hospital at Chiba recently submitted his research on night-blindness in the army. He examined all soldiers in two regiments in which he served and found many cases of night blindness. Examination of the soldiers' food convinced him that the direct cause of this disease is not the lack of vitamin A, but the influence of the direct light of the sun during daytime drill, and overwork. He states that night-blindness frequently develops in aviators who fly from daytime to night and in infantrymen, who drill during the day and work in the evening. His opinion has alarmed the military authorities and they have undertaken a closer investigation of this problem.

Medical Bills in the Diet

A bill providing for the eugenic protection of the race, which was drawn up by the Japanese Eugenic Society, was presented for the first time in the diet. The bill proposes sterilization of criminals, persons with malignant hereditary diseases and similar cases. It is doubtful that the bill will be passed by the houses.

The lower house has agreed on new regulations to improve the status of midwives. This bill was presented last year but was not passed by the upper house. It is expected to be passed this year.

Regulation of School Lunches

The official regulation of school lunches in primary schools was first undertaken by the office of education in September 1932 to provide free lunches for school children who are undernourished or come to school without lunch. The office of education divided 513,330 yen among the fifty-three local governments for the following seven months in that fiscal year. During that period the system was put in force among 6,491 villages and towns and the lunches were given in 11,047 schools.

The lunches were sold for 4 sen, but they consisted of nutritious food. As this system was planned to be an educational facility and not mere relief work, the school lunch was given to any child also who wanted it at his own expense. The total number of lunches at public expense amounted to 29,232,438. With the experience that has been gained the lunches will be better and will be served in more schools this year.

Memorial to Noguchi

In memory of the late Dr. Hideyo Noguchi of the Rockefeller Institute, a hall will be built on the site of the cottage where he was born beside Lake Inawashiro in northeastern Japan. The committee aims to collect 100,000 yen to erect the hall and to repair the old house where his parents and brothers and sisters lived. In the hall will be kept various articles he had used, some sent back from America. Marquis Okuma and Dr. Shimjyo, president of the Kyoto Imperial University, are members of the committee.

Personal

Dr. M. Nagayo, chief of the Epidemic Research Institute in Tokyo, resigned last year to become dean of the medical department of the Tokyo Imperial University. Dr. Y. Miyagawa of the same institute will succeed him.

Dr. K. Sudo, who is noted for his study of medical chemistry, died, January 7, at the age of 63. He retired in 1932 from his position as president of the Kanazawa Medical College. He was a self-taught man in the real sense and had never been to college. He obtained the doctorate through the examination for practitioners. For a short time he practiced medicine in Tokyo but soon gave it up and began research in medical chemistry.

Mr. Gunn of the Rockefeller Foundation was guest of honor at the home ministers' dinner in recognition of his services in establishing an institute contributed by the foundation for training medical experts and workers.

Prof. S. Camboss of the medical college of São Paulo, Brazil, came to this country, January 22, with about fourteen medical students for an inspection tour. This was the first medical party to visit here from South America. All medical schools united in welcoming them. They visited medical centers all over the country for about one month. Dr. Camboss gave a lecture on blastomycosis at the meeting of welcome held by the medical and dental associations in Tokyo soon after they arrived.

Marriages

STANLEY EDWIN MCCLURE, Monon Ind., to Miss Marian McGowan of Mankato, Minn., in Columbia City, April 22.

PAUL EMANUEL LANDMANN, Johet Ill., to Miss Aileen Marie Burkhardt of Dwight, at Plainfield, May 12.

ROY LESLIE KENWARD, Melvin, Ill., to Miss Frances Nonnenmacher of Dewitt, Iowa, at Watseka, May 5.

PARKER C. HARDIN, Arkansas City, Kan., to Miss Catherine Shaffer of Charleston, Ill., May 19.

FRANK HART PRIOR to Miss Elizabeth Skummer Bagley, both of Colorado Springs, May 22.

HALDOY CHARLES KRAFT to Miss Mary Amanda Baker, both of Noblesville Ind., May 10.

WILSON GRAFTON CLAGETT to Mrs. Mary Campion Laurel, both of Dayton Ohio April 29.

REASON LOUIS COPE, Marksville La. to Miss Hazel Marquez of New Orleans, April 28.

JONAS BERK RAYMAN Toledo, Ohio, to Miss Lila Tobin of Miami Beach, Fla., May 22.

NORMAN E. FISHER, Toledo, Ohio, to Miss Jeanne Littwitz of Dayton, May 30.

JAY DONALD MILLIGAN to Miss Leone Daus both of Elgin, Ill., May 16.

Deaths

Carl Arthur Hedblom, since 1926 professor of surgery at the University of Illinois College of Medicine, Chicago, died suddenly, June 6, of coronary thrombosis, while attending a meeting of the American Surgical Association in Toronto, Canada. Dr. Hedblom was born in Dayton, Iowa, March 5, 1879. He was educated at the Colorado College where he received his B.A. in 1907, M.A., in 1908, and an honorary D.Sc., in 1921. In 1911 he received his M.D. from Harvard University Medical School and a Ph.D. from the Mayo Foundation of the University of Minnesota in 1920. He was an intern at the Massachusetts General Hospital from 1911 to 1913 and then went to Shanghai, where he was professor of surgery at the Harvard Medical School in China until 1916. In 1916 he entered the Mayo Foundation as a fellow in surgery and from 1919 to 1924 was head of the section on general and thoracic surgery at the Mayo Clinic. Dr. Hedblom was professor of surgery at the University of Wisconsin Medical School, Madison, from 1924 to 1926, when he came as professor of surgery to the University of Illinois College of Medicine. He was a member of the Society of Clinical Surgery, American Surgical Association and the Western Surgical Association, member and past president of the American Association for Thoracic Surgery and fellow of the American College of Surgeons. Dr. Hedblom was head of the surgical department at the Research and Educational Hospital of the University of Illinois and senior surgeon to St. Luke's Hospital, consulting surgeon at the Edward Hines Jr. Hospital, Hines, Ill., and the Municipal Tuberculosis Sanitarium.

Louis de Lotbiniere Harwood, Montreal, Que., Canada, School of Medicine and Surgery of Montreal, Faculty of Medicine of the University of Laval at Montreal, 1891, dean and professor of gynecology, University of Montreal Faculty of Medicine, fellow of the American College of Surgeons, corresponding member of the Surgical Society of Paris, officer of the Legion of Honor of France, first vice president of the Association of French-Speaking Physicians of North America, on the staff of L'Hôpital Notre-Dame superintendent of the Radium Institute of the Province of Quebec, aged 68, died suddenly, May 15.

Carroll W. Allen, New Orleans, Tulane University of Louisiana Medical Department, New Orleans, 1901, formerly professor of clinical surgery at his alma mater and professor of clinical anesthesia at the graduate school of medicine, fellow of the American College of Surgeons, aged 59, author of "Local and Regional Anesthesia", on the staffs of the Touro Infirmary and the Southern Baptist Hospital, where he died, April 14, of heart disease and diabetes mellitus.

Calvin Fremyre Barber, Brooklyn, College of Physicians and Surgeons in the City of New York, medical department of Columbia College, New York, 1882, fellow of the American College of Surgeons, for many years on the staffs of the Kings County Hospital, Coney Island Hospital and the Samaritan Hospital, chairman of the board of the Caledonian Hospital, aged 74, died, May 12.

Edwin A. Stevens, Mayfield, Ky., University of Louisville (Ky.) School of Medicine 1885, past president of the Graves County Medical Society and vice president of the Kentucky State Medical Association, formerly member of the board of education and mayor, aged 70, medical superintendent of the Mayfield Hospital, where he died, May 4, of cerebral hemorrhage.

Stephen Andrew Mahoney, Holyoke, Mass., Harvard University Medical School, Boston, 1889, member of the New England Obstetrical and Gynecological Society and the New England Surgical Society, fellow of the American College of Surgeons, on the staffs of the House of Providence and the Holyoke Hospital, aged 71, died, March 30, of coronary thrombosis.

Joseph L. Spruill, Jamestown, N. C., University of Maryland School of Medicine, Baltimore, 1895, past president of the Seaboard Medical Association and the Guilford County Medical Society, aged 63, medical superintendent of the Guilford County Tuberculosis Sanatorium where he died, May 5, of carcinoma of the urinary bladder with metastasis.

Sidney B. MacLeod, Chicago, Northwestern University Medical School, Chicago, 1897, past president of the American Association of Railway Surgeons, fellow of the American College of Surgeons, on the staff of the Jackson Park Hospital, aged 59, died, April 3, of coronary thrombosis and appendiceal abscess.

Albert Heman Ely, Cold Spring Harbor, N Y, College of Physicians and Surgeons in the City of New York, medical department of Columbia College 1888, member of the Medical Society of the State of New York, for many years on the staff of the Southampton (N Y) Hospital, aged 73, died, April 26, in the Huntington (N Y) Hospital

Wilfred Anthony Ash ♂ Seattle, Creighton University School of Medicine, Omaha, 1923, fellow of the American College of Physicians, aged 37, on the staffs of the Harbor View Hospital and the Providence Hospital, where he died, April 17, of pneumonia, following an injury received in a fall in his garage

Fulton R Stotler, Wilkesburg, Pa, Jefferson Medical College of Philadelphia, 1869, member of the Medical Society of the State of Pennsylvania for many years director of the city board of public education physician in charge of the Home for Aged Protestant Men and Couples, aged 86, died, April 28

Joseph Andrew Smith, Worcester, Mass, College of Physicians and Surgeons, Boston 1914, member of the Massachusetts Medical Society also a dentist, veteran of the Spanish-American War aged 59, formerly on the staff of St Vincent Hospital, where he died, April 16, of chronic myocarditis

Isaac Beckett Smith, Brooklyn College of Physicians and Surgeons in the City of New York, Columbia University, 1891, formerly chief of the bureau of preventable diseases, state department of health on the staff of St Mary's Hospital aged 68, died April 10 of coronary thrombosis

Harry Floyd Emert ♂ Sarles, N D, University of Minnesota College of Medicine and Surgery, Minneapolis, 1911, president of the North Dakota State Board of Medical Examiners formerly mayor of Sarles, aged 48, died, May 8, in a hospital at Devils Lake, of pneumonia

Harry Flower Shipley, Granite, Md, Baltimore University School of Medicine, 1898 for many years physician at the Woodstock (Md) College and deputy health officer of Baltimore County aged 60, died, May 10, in the University Hospital, Baltimore, of cerebral hemorrhage

Edwin Knickerbocker Losee, Upper Red Hook, N Y College of Physicians and Surgeons in the City of New York medical department of Columbia College New York, 1888 member of the Medical Society of the State of New York, aged 67, died April 13, of embolism

Hayward Warren Cushing ♂ Boston, Harvard University Medical School, Boston, 1882, member of the American Surgical Association, fellow of the American College of Surgeons consulting surgeon to the Boston City Hospital, aged 79, died, May 8, of cerebral hemorrhage

Winfield Bruce Anderson ♂ Brooklyn Long Island College Hospital, Brooklyn, 1917, served during the World War, on the staffs of the Bay Ridge Sanitarium, Midwood Sanitarium, Victory Memorial Hospital and the Samaritan Hospital, aged 39, died, May 20

Jere Dewey Eggleston ♂ Meriden, Conn College of Physicians and Surgeons in the City of New York, medical department of Columbia College, New York 1879 formerly on the staff of the Meriden Hospital, aged 80, died, May 26, of cerebral hemorrhage

O P Nuckols, Pineville Ky, University of Tennessee Medical Department, Nashville 1891 member of the Kentucky State Medical Association secretary and past president of the Bell County Medical Society, aged 72, died suddenly, in April, at Middlesborough

James Merle Scribner ♂ Lowell Mass, Tufts College Medical School, Boston, 1927, member of the New England Obstetrical and Gynecological Society on the staff of St Joseph's Hospital, aged 31, died, May 11, at his home in West Medford

Charles Fremont Bennett, Pomona, Calif, University of Michigan Medical School, Ann Arbor, 1879 aged 78 died January 18, in the Los Angeles General Hospital, of diverticulum of the esophagus, pulmonary tuberculosis and bronchopneumonia

William W Smith, Louisville Ky, Medical College of Ohio, Cincinnati, 1891 formerly member of the state legislature, aged 66 died, May 2, in St Anthony's Hospital, of a fracture of the hip sustained when he tripped on a rug in his home

Samuel Schneider, New York University and Bellevue Hospital Medical College, New York 1899 member of the Medical Society of the State of New York, aged 61, died, April 14, in the Park East Hospital, of carcinoma of the colon

George Ellis Towle, Wisconsin Rapids, Wis Marquette University School of Medicine, Milwaukee, 1913, served during the World War, formerly health officer of Marshfield, aged 46, died suddenly, February 27, of cerebral hemorrhage

Joseph Henry Litterer ♂ Nashville, Tenn, Vanderbilt University School of Medicine, Nashville, 1917, member of the American Society of Clinical Pathologists, served during the World War, aged 42, died, April 4, of heart disease

Pinkard Charles Downs Jr, Chicago, Meharry Medical College, Nashville, Tenn, 1916, member of the Illinois State Medical Society, aged 50, died, March 15, in the Cook County Hospital, of pericardial effusion and coronary occlusion

Gaius Fabius Brooks, Ysleta, Texas, University of Nashville (Tenn) Medical Department, 1883, Vanderbilt University School of Medicine, Nashville, 1889, member of the State Medical Association of Texas, aged 80, died, April 28

Aaron R Elder, Harrisonville, Mo, Missouri Medical College, St Louis, 1884, member and at one time president of the board of education, county health officer, on the staff of the Harrisonville Hospital, aged 80, died, April 5

Wilson Adolphus Allen, Rochester, Minn, Hahnemann Medical College and Hospital, Chicago, 1879, member of the Minnesota State Medical Association, aged 100 died, May 11, in a local hospital, of injuries received in a fall

Edgar Voorheis Beardslee ♂ Detroit, University of Michigan Medical School, Ann Arbor, 1916, aged 49 on the staff of the Highland Park (Mich) General Hospital, where he died, May 10 of carcinoma of the colon

Thomas Jobson Swantz, South Bend, Ind, Northwestern University Medical School, Chicago 1907, member of the Indiana State Medical Association, aged 56, died, May 10, of myocarditis and diabetes mellitus

Frank Emens, Trinity, Ala, Hospital College of Medicine Louisville, 1898, member of the Medical Association of the State of Alabama, member of the board of education, aged 64, died, April 26 of pneumonia

Charles Samuel Shultz ♂ Spirit Lake, Iowa, State University of Iowa College of Medicine, Iowa City, 1891 secretary of the Dickinson County Medical Society, aged 70, died, April 12, of pneumonia

Lucius E Ellis, Orrick Mo University Medical College of Kansas City, 1905, member of the Missouri State Medical Association, aged 56, died April 20, of malignant brain tumor and nephrectomy

Colin William MacDonald, Boston Bellevue Hospital Medical College New York 1887, member of the Massachusetts Medical Society, aged 76 died, April 19, of chronic myocarditis

Noah Albert Grant Tesson, Kansas City, Mo, Kansas City Medical College, 1895 member of the Missouri State Medical Association, aged 70, died, February 23, of coronary sclerosis

John Calvin Stever, Bambridge, Pa, Jefferson Medical College of Philadelphia, 1877, member of the Medical Society of the State of Pennsylvania, aged 81, died, April 8, of arteriosclerosis

Samuel Warren Miller, Denver, Jefferson Medical College of Philadelphia, 1884, member of the Colorado State Medical Society, aged 77, died, April 10, in Salt Lake City, Utah

Charles Samuel Layton, Eloise, Mich Detroit College of Medicine, 1897, formerly on the staff of the Eloise Hospital aged 62, died, April 20, in Detroit, of cerebral hemorrhage

Minard J Armstrong, Springfield, Mo (licensed in Missouri in 1905) member of the Missouri State Medical Association, aged 53, was found dead, April 13 of angina pectoris

Edward John Stephens, Utica, N Y, Albany (N Y) Medical College, 1881, aged 79 formerly on the staff of the Faxon Hospital, where he died, April 6, of chronic myocarditis

Charles Bartlett Dearborn ♂ Mount Sterling Ill, Rush Medical College, Chicago 1890, secretary of the Brown County Medical Society aged 66, died, May 16, of cerebral thrombosis

William Perry Stone, Palmer, Tenn, Chattanooga (Tenn) Medical College 1897, member of the Tennessee State Medical Association aged 66 died suddenly, April 15, of heart disease

Bureau of Investigation

STARDOM'S HOLLYWOOD DIET

In Which the Obese Are Again "Kidded by Experts"

"Stardom's Hollywood Diet, a Reducing Food," seems to be essentially 2¼ cents' worth of soya bean flour faintly flavored with cocoa and salt and sold for from \$1.00 to \$2.00!

The product is put on the market by the Hollywood Diet Corporation of Chicago. The men behind it are reported to consist of two salesmen and an attorney. So far as is learned, no physician is an officer or director of the corporation. To include a lawyer in a company is a common set-up in the field of nostrum exploitation. The essentials to success in this field are salesmanship and enough legal talent to keep the salesmen from committing any technical violation of the law. It is quite unnecessary that any one in such a business should have even the faintest knowledge of medicine, pharmacy or chemistry. What sells a nostrum is the advertising, not merit.

In spite of the renaissance in curves, as typified by the popularity of Mae West, many American women still seek the

slim figure by short-cut methods, and obesity cures are still popular. Such cures vary widely in composition. Some of them are for external application—salts to be put in the bath water, creams or soaps to be rubbed on the surface of the body. Others are for internal use—purgative pills, salines sold as "salts" or "crystals," chopped-up laxative herbs sold as "teas," thyroid substance in pills or capsules, and, even more recently, the dangerously potent dinitrophenol. Within the past year or two still another method of capitalizing on the desire for the slim figure has appeared. It consists in selling under a fancy name some simple food product of low caloric value which the obese are urged to use in the place of two of the three daily meals. Stardom's Hollywood Diet belongs to the latter group.

Naturally in putting over a simple inexpensive food product as an obesity cure sold at an exorbitant price, skilful advertising is called for. Much of the advertising of Stardom's Hollywood Diet is buncombe to the nth degree. Thus:

Within thirty days you will thrill to your loveliest image you will radiate a vital more slender charm.

You'll be quite thrilled at the ease with which Stardom's molds your body into slender proportions almost before you realize it you will find your flabby tissues becoming firm slender and alluring.

After reducing with Stardom's Hollywood Diet you should look as young as you weigh and feel as young as you look. Yes you really should.

The possibility of your having an exciting type of Hollywood figure is now so real as to be actually breath taking.

This is some of the tosh that is dished up to the obese in order to get them to pay an extraordinary price for a most ordinary product

In a circular dealing with this nostrum there appears under the heading 'Certified—for Your Protection' what purports to be a certificate issued by a Chicago chemist. The certificate makes this chemist declare that the preparation contains an "abundance" of lecithin. In a letter to the Bureau of Investigation the chemist states that he actually reported that there was "only a trace" of lecithin! The published certificate also makes the chemist say

'Stardom's Hollywood Diet is so well balanced and contains such complete and superior proteins, minerals, lecithin and vitamins that it can well replace one or two fat-forming meals each day without lowering your resistance or vitality. It will maintain the necessary reserve of the human body with nourishing elements that will not end in FAT.'

From the explanatory letter sent to the Bureau of Investigation, it seems that the statement just quoted is a pure invention of the advertisers of Stardom's Hollywood Diet and formed no part of the chemist's original report.

Requests for information regarding Stardom's Hollywood Diet have poured in from all parts of the country, from the Atlantic to the Pacific and from Canada to the Gulf. For that reason, it was felt justifiable to investigate the preparation, so that information could be furnished both physicians and laymen. The report from the A M A Chemical Laboratory follows.

REPORT

"The Bureau of Investigation requested the A M A Chemical Laboratory to investigate Stardom's Hollywood Diet. Original packages were purchased on the open market. The label bore the following notation:

Stardom's Hollywood Diet—A Reducing Food Containing Vitamins A B C D E. No Drugs. No Laxatives. A Pure Food Product. Reduce With Safety.

"A cursory examination indicated that the product was apparently not a drug but consisted of a 'feed.' It was deemed advisable to have the product analyzed by a consulting laboratory specializing in foods and feeds, rather than by the A M A Chemical Laboratory. The consulting laboratory reported that the product contained approximately 180 Gm (6 oz) of essentially vegetable material having a brown color and an odor resembling chocolate, it also contained a small amount of chloride. In addition, the product was also referred to a well-known food authority and microscopist, who reported that the sample consisted essentially of soya bean flour mixed with cocoa. Quantitative determinations yielded the following:

	per cent
Moisture	3.1
Crude Protein (N \times 6.25)	38.3
Crude Fat	8.4
Ash	8.8
Crude Fibre	2.3
Nitrogen Free Extract	39.1
Chloride calc. as sodium chloride	1.73

"The foregoing compares favorably with what would be expected for soya bean flour though it is a little lower in protein than the average soya bean flour. This may be because of the dilution resulting from the addition of cocoa, or it may be due to a lower protein content in the soya bean flour used in the preparation of the product.

"From the foregoing analysis it appears that Stardom's Hollywood Diet consists essentially of soya bean flour or meal to which has been added cocoa and some salt. No other constituents were found in the mixture.

From the chemical and microscopical analysis, it seems that Stardom's Hollywood Diet is essentially soya bean flour to which has been added a minute amount of cocoa and salt. Ordinary soya bean meal can be purchased for about \$33 a ton. Refined soya bean flour sells for about \$5 or \$6 a hundred pounds. Assuming that the higher-priced refined soya bean flour is used in making Stardom's Hollywood Diet, there would be in a package which is labeled \$2 (but is frequently sold for \$1) 2¼ cents' worth (6 ounces) of soya bean flour, with an insignificant amount of cocoa and salt. This should allow a handsome margin for advertising, overhead and exploitation.

The woman who seeks a sylph figure is told to substitute a teaspoonful of the product to be taken in the place of breakfast and another teaspoonful to be taken in the place of luncheon. A heaping teaspoonful of Stardom's Hollywood Diet was found to weigh 8 grams. This would mean that the

recommended breakfast and luncheon each would furnish less than 31 calories. The average fuel requirement for the breakfast of a woman leading a sedentary life is between 400 and 600 calories, the total fuel requirements for the day ranging from 1,800 to 2,300 calories. In her excellent book, "Feeding the Family," Doctor M S Rose, professor of nutrition at Teachers College, Columbia University, outlines a suggested reducing diet for an overweight woman. For a proposed breakfast in this diet Dr Rose recommends a medium sized apple, one egg, a slice of toast, a cup of coffee, and one and a half teaspoonfuls of skim milk, having a total fuel value of 200 calories. There is then to be taken at 10.30 a.m. some bouillon and a water cracker (22 calories), a luncheon, comprises a medium serving of lean cold roast beef, two thin slices of rye bread, some lettuce and cottage cheese salad (285 calories), at 4.30 a cup of tea and a water cracker (10 calories), dinner includes a large serving of boiled cod with lemon, one-half medium sized boiled potato, a large serving of cauliflower, a scant teaspoonful of butter, watercress and egg salad with a small amount of French dressing, half an orange, and a demi-tasse of black coffee, making for the dinner 490 calories. Then at bedtime a half cup of hot skim milk, making an additional 45 calories, or a total fuel value for the day's food of 1,052 calories.

Such a diet has balance, which may be as important as total calories. The diet recommended in the exploitation of the nostrum Stardom's Hollywood Diet must of necessity be hopelessly unbalanced. Then there is always the likelihood that a woman who has simply had a teaspoonful of soya bean flour for her breakfast and another teaspoonful of the product for her luncheon will become so ravenously hungry by dinner time that she will eat twice as much as she would under ordinary conditions.

It is hard to make the public understand that the reduction of weight is not necessarily the simple process that so many consider it. The senseless taking of "salts," "crystals" and the innumerable other purgatives that are sold as obesity cures, the unwise self-administration of the potent thyroid and of the much more dangerous dinitrophenol, must, in the aggregate do the public health of the country incalculable damage. Because individuals taking such treatments only occasionally die from the results, the belief has developed that there can be no particular harm in taking the innumerable nostrums put out by shrewd exploiters who literally live on the fat of the land.

Correspondence

HYPERPARATHYROIDISM

To the Editor.—In THE JOURNAL, May 26, page 1764, appears an editorial entitled "Hyperparathyroidism: A Chapter in Successful Laboratory Research." This editorial presents a misleading picture. Mandl is a surgeon, the finest piece of writing that has ever been done on this subject is by Donald Hunter of London, the interest in parathyroidism in America is due more to the clinical work of Dr. Max Ballin than to any other person or group of persons. The American Medical Association conferred its gold medal on Dr. Ballin for his presentation of this subject at the New Orleans session. The enormous importance of the roentgenologists' contributions to this subject is entirely ignored—such work as Camp's at the Mayo Clinic.

Most unfortunate of all, the most positive statement in the editorial is incorrect, namely, that the operation should not be attempted unless the blood chemistry is thus and so. Aside from ample clinical examples which have come under my observation, I would refer you to one of the Mayo staff meeting reports stressing the point that there are classic cases in which the tumor has been demonstrated that have never shown an abnormal blood chemistry.

At the Toronto meeting of the American Orthopedic Association, one of the authors referred to in the bibliography of

your editorial took Drs Ballin and Funston to task for asserting that generalized osteitis fibrosa cystica is always associated with parathyroid tumor, saying that in Boston they had a case in a sea captain who had been operated on some three times or so and no parathyroid tumor was present. Since that time, on the insistence of the patient, and not because of the doctor's confidence in his blood chemistry results, the tumor has been located—too late, however, to help the patient.

The chapter of our knowledge of parathyroidism is not a subject that the blood chemist should select to deify his guild, but rather a brilliant example of the results that can be obtained when the clinician, roentgenologist and pathologist work together for the common good.

Pathologist, Harper Hospital

YAWS AND SYPHILIS

To the Editor—In THE JOURNAL, January 13, page 148, was a communication from Dr C S Butler of New York dealing with the much debated topic of yaws and syphilis. With reference to a critical review that I made of the subject, which appeared in the *Tropical Diseases Bulletin*, the statement is made that "Blacklock proves the proposition that yaws and syphilis are the same thing." This appears to be a misapprehension on the part of Dr Butler.

My incentive in endeavoring to appraise the significance of the usual diagnostic points by which yaws is said to be distinguishable from syphilis was the necessity for putting the matter as clearly as possible for students. All that emerged was that the usual differential points will not in fact serve as diagnostic; this, however, does not appear to warrant the conclusion that I have proved that yaws and syphilis are the same. It is necessary to emphasize that this problem of yaws and syphilis is by no means easy to solve and is not yet solved.

If, as Dr Butler complains, I did not make reference to his work, it was possibly because he is one of those who consider that it has already been settled and because the views of authors who had previously reached this conclusion were already included in my article. For example, I referred to the work of Branch, who, as early as 1907 in a paper in the *Annals of Tropical Medicine and Parasitology* (1:371, 1907), wrote, "We have seen that it is only in the frambesial eruption that yaws differs from syphilis, but even the frambesia is identical with the syphilitic papilloma on a moist surface."

Dr Butler later discussed the contents of my paper in an editorial article in the *American Journal of Clinical Pathology* (2:239 [March] 1934). Here, in addition to the misapprehension of my views mentioned, there is introduced a very definite misrepresentation in the following paragraph: "Professor Blacklock quotes many more or less important writers along the line of the yaws-syphilis investigations but has little to say about his own countrymen who have borne the brunt of it in defense of what they knew to be true. Nor aught but silence has he for the group of Americans, principally U S naval medical officers, who have, by research and writing, defended Hutchinson's view for the past thirty years."

The reader derives from this statement a belief that the work of Americans on the question of yaws and syphilis has been entirely ignored in my papers. That this is not so must be clear when I point out that the following American authors are quoted by me in my two articles: W J Baetz, E W Goodpasture, H H Hazen, E H Hudson, G R Lacy, F B Mallory, Thomas McCrae, J E Moore, William Osler, G W Raiziss, M A Reasoner, Otto Schobl, A W Sellards, Marie Severac, J H Stokes and F L Zimmermann.

Especial reference was made by me to the very important experimental work on the subject carried out by Sellards and

Goodpasture in 1923 and Sellards, Lacy and Schobl in 1926, and to the valuable contributions of many other American authors.

I am sorry to occupy your space with this sort of correspondence, but it is necessary to state these facts so that American readers may see from them that Dr Butler's remarks are not justifiable.

THERAPEUTICS OF RUBEFACIENTS AND OF COUNTERIRRITATION

To the Editor—Dozens of remedies to be rubbed in are advertised by radio newspapers, posters and pamphlets for the treatment of any and all chest disturbances, whether of a respiratory muscular or bony origin. If there are any benefits that can be gotten from their use, exactly what can be confidently looked for? The desire to rub something on in my experience of thirty years is helpful only to those desiring to do something. As no known drug to date will destroy any bacillus or coccus in the chest, what possible benefit can result in smearing the chest with a nialodorous greasy ointment? Is it possible that there are reflexes that I know nothing about? I want to know. A patient with a temperature of 102 to 104 F wrapped in woollens covered with smelly greases is an object of sincere pity to me. If there is anything at all to such treatment, will you explain it all thoroughly? Millions of dollars are being expended annually for patent greases that I feel confident are highly injurious. Turn on the light. Please omit name.

M D Oklahoma

ANSWER—For purposes of the brief review of referred pain and counterirritation necessitated by our correspondent's inquiries, the central nervous system may be considered to receive sensory stimuli from three sources: (a) the skin, (b) the connective tissues, muscles, tendons and joints, and (c) the viscera. It is well known of course that, when painful stimuli or varying temperatures and pressures are applied to the skin, the site, nature and degree of these applications come fairly accurately into the consciousness, and it is also a matter of common experience as well as of experimental observation that some sort of sensory impulses reach the brain from the deeper lying structures and enable one to possess at all times an awareness of the position of one's limbs, furthermore, sensations of pain and pressure may also arise from muscles, tendons, joints and connective tissues. But in health nothing comes steadily into consciousness that reminds one of the presence of the visceral organs, though many of them are continuously in active motion. The parietal pleura may give rise to pain because of its partial innervation by the intercostal nerves, but the lungs and heart are insensitive except to traction. The parietal peritoneum also is sensitive, especially to traction, the mesenteries are sensitive to traction but they, as well as the substance of the stomach (including the mucosa), the intestine and the liver may be cut without pain, as may the kidneys (after removal of the fatty capsules) and the bladder, though the latter will not submit to being pulled. It is probable that the pains of intestinal colic, labor, dysmenorrhea, peptic ulcer and the distended liver of cardiac decompensation are due to changes in the tension of the parietal peritoneum and the mesenteries, for such diseases as pulmonary tuberculosis, chronic nephritis and carcinoma of the liver may be entirely painless. Nevertheless the allegedly insensitive organs may at times register the insult that is being offered them by causing certain areas of skin to become both painful and hyperesthetic (hypersensitive) to usual stimuli. This is the phenomenon that is called "referred pain" and it is explained as follows:

The development of the skeletal muscular and nervous structures of the human as of all other vertebrate embryos is of a segmental nature, as is evidenced by the fact that the afferent (toward the brain, i e, sensory) fibers in the dorsal roots of the spinal nerves come from definitely segmented areas of the skin. Some of these areas are lower than the segments of the cord which their nerves enter because of the downward course taken by the nerves during growth, but by severing all the dorsal roots save the one in question at the moment it is easy

to observe the relationship of the remaining clearly demarcated area of skin sensitivity to the segment of the cord at which the nerve enters. The muscles are also considerably displaced from their primitive positions during development, but it is nevertheless possible to trace their nerves also to a portion of the cord which was a part of the same segment from which the muscles originally derived. Now the dorsal roots also receive afferent fibers from the viscera, they follow the course of the autonomic nerves but they are distinctly not a part of the autonomic nervous system, since they do not form synapses in any of the ganglions and plexuses of this system and have been shown to be similar in structure and to have had an analogous segmental origin as the spinal nerves from the muscles and skin. The internal organs have descended too during development but their afferent nerves go back to the portion of the cord representing in each instance the segment from which both the nerves and the organ developed. If one such segment of the cord is considered—for example, a certain left cervical segment—into whose posterior spinal roots there enter sensory fibers from both the organs and skin areas that originally budded off from this segment one can understand how stimuli passing up from the organ may be reflected in the skin area—how coronary pain can be felt in the left shoulder and

as well as in a few instances of artificially induced referred pain in normal subjects, and were able in each case to obtain considerable, often complete, relief.

The accompanying diagram shows the usual points of referred pain and the sites at which local application of "counter irritants" may be expected to be the most helpful. Why irritation over the painful area, which would seem to be just the opposite of the method successfully employed by Weiss and Davis, should cause the disappearance of pain is also not entirely understood, but it is worthy of note that the congestion and burning characteristic of rubefacient action are often succeeded by more or less anesthesia. Macleod (*Physiology and Biochemistry in Modern Medicine*, ed 6, 1930) prefers to relate the phenomenon to the competition of incompatible reflexes for the control of a common motor path, in which case the one that will succeed in gaining control and in suppressing the other will depend on the relative strengths of the stimuli. He cites an interesting experiment of Head, who was an early investigator in this field. "The tip of the glans penis is supplied with receptors for cold and pain but may be devoid of heat spots. If it is dipped into water at 40 C the pain spots alone are stimulated and a disagreeable painful sensation results. If the temperature is raised to 45 C the cold spots also are stimulated and the pain is displaced by a vivid sensation of cold. About the corona of the penis heat spots also occurs. If this region is also immersed the quality of the sensation changes to one of exquisitely pleasant warmth. If the water employed in the experiment is at a temperature higher than 45 C the painful sensation persists and no sense of warmth is felt. The sensations of pain and warmth are incompatible and cannot occur simultaneously." Edmunds and Gunn (*Cushny's Pharmacology*, ed 9, 1928) think that something more than the relief of pain is at times induced by counter irritation and that most probably an alteration in the caliber of the vessels is promoted. However undeniably valuable as the effects are at times, our correspondent is certainly warranted in his opinion that money is being wasted in enormous amounts on "patent" counterirritant greases. Beckman (*Treatment in General Practice*, ed 2, 1934) describes the preparation and uses of mustard poultices and plasters and turpentine stupes. It is probable that with these agents alone all that is possible with this type of therapy may be accomplished.

Usual points of referred pain and sites at which local application of 'counterirritants' may be expected to be the most helpful

arm and over the sternum and up into the anterior neck and jaws. Perhaps it is not precisely understood, but at least the close association of fibers from distant and unlike parts at the point of their common embryonal origin is seen. Clear understanding of the subject has been attained by no one as yet, but the hypothesis of Mackenzie (*Symptoms and Their Interpretation*, ed 4, 1920) is a distinct advance toward exact knowledge. According to this conception, irritation of an organ causes a play of impulses to pass along its afferent fibers to their segment in the cord higher than this they cannot rise for some reason (at least they do not come into the consciousness as "pain"), but the incessant bombardment of these impulses causes an "irritable focus" to appear in the cord at this point. At the same time, however, normal afferent impulses from the skin and muscles are reaching this segment and when they pass through the irritable focus they are sufficiently disturbed to signal pain to the brain. What comes then into consciousness is the usual pain in the skin, though the stimulus was actually applied higher up the nerve. Weiss and Davis (*Am J M Sc* 176 517 [Oct] 1928) have felt that a test of this hypothesis would be to block the afferent cutaneous impulses from painful skin areas in visceral disease by infiltration of the site with a local anesthetic. This they did in a number of cases of referred pain of cardiac, pulmonary, pleural, esophageal, gastric, gallbladder, cecal, kidney and pelvic origin

USE OF CAFFEINE SODIOBENZOATE IN PREMATURE INFANTS WITH KIDNEY DISTURBANCE

To the Editor—I would greatly appreciate a discussion of the proper management of the following case keeping in mind an absence of hospital and laboratory facilities. A premature infant of approximately eight months was very weak from birth and was unable to nurse. It was kept alive by incubator oxygen intraperitoneal saline solution tube feedings of breast milk and intramuscular injections of caffeine sodiobenzoate. The caffeine sodiobenzoate is the product of a reliable drug house. At the end of four or five days the infant improved and was able to take its feedings from a small bottle. However a sterile abscess had formed at the site of an earlier injection of caffeine sodiobenzoate. Since the abscess showed no tendency to absorb it was opened widely with the evacuation of much semifluid necrotic material no frank pus being present. About this time edema was noted about the face and extremities the urinary output having been scanty since birth. In spite of wide incision and daily irrigations of the wound with a sterile nontoxic solution the wound showed no tendency to heal and the edema progressed to a point of generalized anasarca. During this time almost no urine was passed. This was highly concentrated and contained a large amount of albumin many hyaline casts and a few red cells. On the tenth day the infant died presumably from acute nephritis. Points of interest to me are the following. Should caffeine sodiobenzoate be used for stimulation of the newborn and if so in what dosage? Does sterile necrosis often follow use of this drug in the newborn? In the case reported what means if any could have been used to combat the nephritis other than correct treatment of the wound? Should fluids by mouth have been restricted?

H W DORR M D Ashton Idaho

ANSWER—Caffeme sodiobenzoate may be used as a stimulant in premature infants although its use perhaps is not as frequent as some of the other stimulants. The development of a sterile abscess in the case under consideration should not be attributed to the drug or preparation used necessarily but rather to the infant's poor circulation and lack of absorption.

Atropine sulphate and epinephrine are frequently given hypodermically to premature infants as a stimulant. Perhaps aromatic spirit of ammonia in a dosage of from one to five drops by mouth is more frequently used. Its action is usually quite satisfactory. In a list of stimulants, brandy and whiskey should be included and, depending on the indications present, may be given in amounts varying from three to ten drops every three hours.

The presence of acute nephritis in new-born premature infants has been observed under a number of conditions. In general

these are considered to be the result of infection. Syphilis should be named as a frequent etiologic factor in the producing of severe kidney changes. Transitory urinary changes may be seen when the mother is having acute nephritis or eclampsia. These changes usually clear spontaneously during the first two or three weeks. The development of "hydrops fetu universalis" has been shown to be related to the presence of nephritis in the mother during pregnancy. Edema in small premature infants is frequently seen during the first days of life, usually affecting the extremities and genitalia. A large number of these are probably the result of a circulatory weakness. The edema may involve the deeper structures and there may be fluid accumulation in the body cavities. The chilling of newborn infants and especially premature infants and the accompanying subnormal body temperature are always a factor in the production of edema. The special forms of edema, sclerodema and sclerema are occasionally seen. It may be impossible to make an absolute differentiation between these.

So far as the treatment is concerned, as a general statement fluids by mouth should not be restricted. The maintenance of adequate fluid intake, normal body temperature and normal elimination are important.

MENSTRUATION AND ABNORMAL BLEEDING IN GIRLS

To the Editor—I have a patient aged 15 years who began to menstruate at the age of 13. Menstruation occurred every twenty-eight days and was normal in amount for a few months. Then she began to flow more freely until there have been times of five months continuous bleeding from the vagina. Of course there has been considerable weakness resulting from this loss of blood. Physical examination has been essentially negative except for secondary anemia. Blood examination about Sept. 1, 1933 showed red blood cells 3,260,000, white blood cells 4,350, hemoglobin 75 per cent. The following treatments have been used with no decrease of flow or improvement in any way: rest in bed, corpus luteum intramuscularly 1 cc daily for ten doses, ergot, calcium lactate, antuitrin S 1 cc daily for ten days intramuscularly, theelin 1 cc intramuscularly every day for seven days, ovarian substance, transfusion of blood from pregnant woman, curettement, negative x-rays every month for seven treatments. Have you any suggestions for further treatments? Please omit name. M D, New York

ANSWER—This girl has had too many different forms of treatment, and apparently not one of them has been used sufficiently long to determine its therapeutic effect. It is assumed that the term negative curettement implies that a normal endometrium was found. From the history, however, a hyperplasia of the endometrium is suggested. Certain of the remedies used are entirely useless in the treatment of this condition, such as ovarian substance and estrogenic preparations (theelin, amniotin and the like). In some cases, Novak has obtained encouraging success with the use of an anterior pituitary-like luteinizing substance obtained from the urine of pregnant women (Antuitrin S, Follutein). However, this form of treatment is usually temporary and must be repeated with each hemorrhage. Nevertheless it is preferable to the use of radiation therapy or operation in a girl of 15 years. Repeated small transfusions will help replace some of the blood that is lost and may improve the quality of the blood. Of course, a thorough general physical examination should be made to rule out any possible systemic cause and careful studies of the blood also should be made. Small doses of thyroid may be tried and occasionally repeated curettements have a curative effect. In some instances insulin produces a cessation of the irregular bleeding. As a last resort about 250 or 300 mg. hours of radium should be employed. This treatment may have to be repeated.

USE OF BLOOD INJECTIONS IN CEREBRAL HEMORRHAGE AT BIRTH

To the Editor—Several days ago I was surprised to hear a lady say the following: When my daughter-in-law's baby was born the doctor used instruments. Three days after the birth the doctor told my son that he would transfer some of his (the father's) blood into the infant to foretell any chance of cerebral hemorrhage which sometimes followed the use of instruments. The lady asked me if I had ever done it. I frankly told her no and what was more I had never heard of its being done nor could I see the reason for waiting three days after the possible cause of hemorrhage before applying the remedy. However, being only a plodding country doctor of thirty-nine years practice I may have missed the technique. I write to you for the information. Is it modern practice to give an infant a transfusion of the father's blood three days after its birth to prevent the possibility of hemorrhage when instruments have been used? This patient lives in Salt Lake City, Utah.

M D, Utah

ANSWER—The practice of injecting blood intramuscularly into babies who are suspected of having sustained intracranial hemorrhage is sanctioned by general usage. The administration of blood has also been suggested as a prophylactic remedy in babies whose birth has been prolonged or difficult or who have been delivered with forceps. It is not possible to explain

exactly why the blood was injected on the third day in the case mentioned. It is known, however, that late hemorrhages may occur, that oozing may continue from the rupture of large or small vessels, and that the amount of damage resulting from a hemorrhage is in direct proportion to the quantity of blood that has been extruded. Briefly, the answer to the query may fairly be stated with the following assumption.

The physician probably suspected late hemorrhage or continued oozing, which led him to administer intramuscularly blood on the third day of the infant's life.

USE OF PATCH TESTS

To the Editor—Please give me your opinion regarding the patch method used in testing with substances such as face powders and soaps, especially in cases in which there is a question of occupational responsibility such as one using soaps and paints also in those who may purchase certain articles of jewelry, ear drops, neck pieces, as furs and jewelry if one were to use the articles such as soap, paint and face powders on the skin or, in other words use a patch test that would be considered reliable as positive proof of that particular article being the cause of dermatitis. Please omit name. M D, Iowa

ANSWER—The question as stated is not entirely clear. Most likely the inquirer desires to have a general opinion of the value of patch tests in the diagnosis of hypersensitiveness to face powders, soaps, and the like. If the condition is a truly allergic one such as a hyperesthetic rhinitis, asthma or eczema, the ordinary method of performing skin tests should be employed. In such instances the materials may be put on scratches made in the epidermis and a positive reaction may be expected in from fifteen to twenty minutes.

If the hypersensitiveness is not of the allergic type, the usual symptom is a dermatitis and scratch tests are of no avail. In such instances, patch tests are of value. The usual types of materials with which patch tests are rational are various house plants, wool, silk, cotton, fur dyes, ointments, lotions, soaps and creams. Synthetic jewelry, rims of spectacles and similar articles may cause a dermatitis and may be adapted to the method of contact tests. A positive patch test indicates that the patient's skin is sensitive to the material. It does not prove that the clinical dermatitis for which the patient consults the physician is necessarily due to that material. In the performance of patch tests it must also be borne in mind that many materials are irritating per se if allowed to be in contact with an individual's skin for any length of time. Hence the use of patch tests with such irritating materials as iodine solutions, mild caustics, tar and cleaning preparations must be carefully controlled by their action on normal persons. In general it may be said that the procedure of specific diagnosis by the patch method has found a considerable and widespread application in the field of dermatology and if used rationally will frequently point out the causative agent of a dermatitis.

CONGENITAL SYPHILIS AND JUVENILE DEMENTIA PARALYTICA

To the Editor—I have a boy aged 9 years under my care for the treatment of congenital syphilis. He has a 4 plus Wassermann reaction of both the blood and the spinal fluid. For the past year he has been treated with bismuth salicylate (1 gram, 0.065 Gm.) intramuscularly at weekly intervals for periods of from six to eight weeks alternated with intravenous injections of neosarsphenamine, in a dosage from 0.2 to 0.3 Gm. every week for eight injections with rest periods of two or three weeks between the series. Following one series of five injections of bismuth salicylate symptoms developed referable to the central nervous system and resembling those of meningeal irritation. The spinal fluid at this time was 4 plus with no evidence of any other infecting agent. He also has a congenital cataract of the left eye. Otherwise he is in fair health and the physical examination reveals no other gross pathologic change. His average weight is 65 pounds (29.5 Kg.). I should appreciate an outline of treatment in this case. Please omit name.

M D, New York

ANSWER—Although other details of the spinal fluid examination than the Wassermann reaction are not supplied, the fact that the spinal fluid Wassermann is strongly positive in a boy of 9 who has no clinical evidence of neurosyphilis leads one to anticipate the possibility of the subsequent development of juvenile dementia paralytica. Treatment with the arsphenamines and heavy metals (bismuth and mercury) would probably not prevent this eventuality, no matter how long treatment was prolonged. Recent experience has shown that fever therapy is applicable to the treatment of juvenile neurosyphilis as well as to central nervous system involvement in the acquired disease. The most favorable type of case for its use is in pre-paretic asymptomatic neurosyphilis. This is the probable situation that confronts the correspondent in this case.

It is generally agreed that, of the various methods of producing artificial fever, malaria is by far the most satisfactory,

both in increased incidence of serologic improvement and in the maintenance of good health (e g, prolonged remissions in dementia paralytica) over long periods. It is suggested, therefore, that this patient be treated with induced malaria. This form of fever therapy should not be given except by a physician who is experienced in its use. After eight to twelve paroxysms of fever have been completed and the malaria terminated by the use of quinine, a short course of six injections of 0.3 Gm of neoarsphenamine at weekly intervals should be given for its combined tonic and antimalarial effect. Immediately on completion of this course, treatment should be started with tryparsamide, which is particularly valuable in neurosyphilis, both congenital and acquired. The average intravenous dose of tryparsamide for a boy of this age and weight would be 15 Gm. Weekly injections should be given to a total of from twelve to sixteen injections to the course, each course being separated by an eight or ten weeks course of injections of bismuth salicylate, 0.1 Gm. No rest periods should be allowed. This form of alternating treatment with tryparsamide and bismuth salicylate should be continued for at least two years after the completion of the malaria and should be controlled by periodic physical examinations and serologic tests of the blood and spinal fluid, carried out at intervals of six months.

Visual damage from tryparsamide need not be a more serious problem in a boy of 9 who is able to cooperate with descriptions of subjective visual sensations than in the adult. The presence of a congenital unilateral cataract is not a contraindication to the use of this drug.

On completion of this outline of treatment the patient should be followed with subsequently repeated physical and laboratory examinations in order to guard against possible progression. Such examinations should be carried out every six months for the first three years and thereafter yearly or biannually for the next fifteen to twenty years.

PROPHYLAXIS OF RINGWORM OF FEET

To the Editor—Where large bodies of men use the same shower baths what prophylactic measures are considered best for the prevention of trichophytic infection of the feet? Bathrooms in barracks have glazed tile floors and walls. I have been using foot tubs containing antiseptic solution for men to step into before entering and after leaving shower baths. The tile floors are scrubbed thoroughly each day. Formerly wooden gratings were used under showers for men to stand on, sufficient gratings being furnished to allow for sunning on alternate days weather permitting. What is the consensus as to the use of wooden gratings? Please omit name.

M D, Virginia

ANSWER—The use of 1 per cent sodium hypochlorite solution in foot baths or 'wells' built into the floor has been shown to be efficient as prophylaxis in ringworm of the feet. It is also cheap. The sodium hypochlorite can be purchased from a number of chemical companies in steel carboys in a strength of 20 per cent. The solution in the pans should be changed every second day. The pans or "wells" are so placed as to necessitate all the men walking through the solution on their way to the shower baths and also just prior to putting on their clothes. A complete description of this method of prophylaxis has been given by

Osborne, E D and Hitchcock, Blanche S. The Prophylaxis of Ringworm of the Feet *THE JOURNAL* August 15 1931 p 453
Osborne E D Putnam E D and Rickloff, R J Personal Experiences in the Prophylaxis and Treatment of Ringworm of the Hands and Feet *New York State J Med* Nov 1 1933

Wooden gratings are of doubtful benefit, especially if the method of prophylaxis as outlined is used.

TYPHOID FEVER CARRIERS

To the Editor—As part of a study I am making of a specific phase of typhoid fever control I am confronted with a number of technical questions and have been unsuccessful in finding the required information. To check the dangers resulting from typhoid carriers some medical authorities advise the removal of the gallbladder. 1 Why does *Bacillus typhosus* settle and propagate in the gallbladder and in what way do surgical measures correct these conditions? 2 What states if any legally require that the gallbladder must be removed to cure a chronic carrier? 3 Why are most of the carriers women? Whatever information you may be able to supply will be greatly appreciated and acknowledgment will be made as to the source of the data. Should you know of some published material that may give the required information references to available material would be of great assistance to me in making this study.

N N WOLPERT New York.

ANSWER—1 Presumably typhoid bacilli are found in the gallbladder during the acute stages of the disease as well as being widely distributed elsewhere in the intestinal tract. It has been suggested that in gallbladder typhoid carriers the

reason the organisms persist is that the gallbladder was diseased prior to the typhoid infection. An analogy has been drawn with the almost universal frequency with which a pathologic condition of the nasal aural pharynx is found in cases of chronic diphtheria carriers.

2 So far as we know, no state requires removal of the gallbladder in chronic carriers, and it would probably be undesirable to make such removal compulsory. Some state health departments encourage it and in Massachusetts, for instance the cost of removal is borne by the state, when the person is a food handler. However, prior to operation, it is important

- (a) To have at least a year elapse after the disease in order to make sure that the carrier condition will not clear up spontaneously.
- (b) To obtain a specimen of bile in order to make sure that the carrier's condition is located in the biliary tract.
- (c) To make sure that the general condition of the patient is good.

3 There is some doubt as to the accuracy of the observations that more women are carriers than men. This fallacy has probably arisen from the fact that the typhoid carriers are usually detected in connection with food outbreaks, and women are more frequently food handlers than men.

TREATMENT OF SECONDARY ANEMIA

To the Editor—Will you please enlighten me as to the following: What definite results may be expected in cases of uncomplicated secondary anemia with the use of copper, iron and other advertised tonics?

M D, New York

ANSWER—Uncomplicated secondary anemia is taken to imply a hypochromic anemia not dependent on such conditions as infection, cancer, chemical poisons, nephritis, cirrhosis of the liver or leukemia. Complications such as infection or severe damage to vital organs are conditions that may inhibit the effectiveness of iron in hypochromic anemia. Uncomplicated hypochromic anemia of the idiopathic type associated with gastric achlorhydria, hypochromic anemia attributable to defective nutrition and chronic blood loss are promptly alleviated by adequate amounts of inorganic iron, as, for example, by the daily administration by mouth of 6 Gm of iron and ammonium citrate 4 Gm of ferrous carbonate or 2 Gm of reduced iron. Defective nutrition leading to hypochromic anemia may arise from deficient diets—common in children and women—from improper absorption from the gastro-intestinal tract and perhaps, from dysfunction in the utilization of iron and blood building substances. Improper absorption may be dependent on numerous factors, such as diarrhea and gastric achlorhydria, the latter condition, together with deficient diets, is often etiologic in the hypochromic anemia of pregnancy.

The addition of copper to therapeutic preparations of iron has not been shown to be of significant value in the anemias of adults alleviated by iron therapy. It has been shown that in young children the addition of small amounts of copper to therapeutic iron preparations in some cases may accelerate the rate of hemoglobin formation, but it is the iron preparation not the additional copper, that is the essential drug for cure. As for "other advertised tonics," the list is a long one but iron in adequate doses remains the sine qua non for uncomplicated hypochromic anemia. The Council on Pharmacy and Chemistry has stated that a search of the literature fails to reveal that, in man, the addition of copper to iron is of any therapeutic advantage. In view of the lack of specific evidence of the value in man of combinations of copper and iron, the Council has not accepted combinations containing copper and iron.

COMBINED SYPHILIS AND TUBERCULOSIS

To the Editor—What is reputed to be the effects good, bad or indifferent of active antisyphilitic treatment in the face of a tuberculosis if the latter is (a) active (b) quiescent or (c) arrested?

REUBEN HOFFMAN, M D. Henryton Md

ANSWER—Infection of a person with both tuberculosis and syphilis is thought by some to exert a good influence on the course of both diseases causing them to run a milder course than if they were uncomplicated. The measures used in the treatment of pulmonary tuberculosis would not be likely to alter this, but antisyphilitic treatment except of the mildest kind, is apt to affect tuberculosis unfavorably, even, in some

cases, bringing on a rapidly fatal military dissemination. Syphilis is a slow disease, while pulmonary tuberculosis may rapidly destroy life. Therefore unless the syphilitic infection is so recent that it is actively contagious, its importance must be rated as slight compared to that of an active tuberculosis.

Iodine holds its place among antisyphilitics because of its power to dissolve inflammatory infiltrates. This action, however useful it may be in the treatment of syphilis, is directly antagonistic to the walling off process, on which the cure of pulmonary tuberculosis depends. It is clummed by some that mercury and bismuth compounds and the arsphenamines exert a milder action of the same sort. Whether this is true or not it is well known that mercury and bismuth compounds, when given too vigorously, lessen resistance. Some forms of arsphenamine are said to lessen coagulability of the blood and thereby predispose to hemorrhage. The febrile reactions caused by arsphenamine are damaging to the phthisis patient. Fever therapy, useful in dementia paralytica and in resistant syphilis in general, is so dangerous in the presence of pulmonary tuberculosis that it is contraindicated except in dementia paralytica that yields to no other treatment, in which the physician feels that the risk is justified.

Active tuberculosis complicated with an old syphilis should be treated as if there were no syphilis present. If it is thought that the syphilis is recent and still contagious, mild treatment with mercury or bismuth compounds may be given, kissing and sexual relations prohibited, and the nurse's hands protected by rubber gloves whenever there is a possibility of contamination by most secretions of the patient. Arsphenamine of any kind should not be used during the febrile stage of tuberculosis. J. E. Moore, discussing the question of the treatment of syphilis in the presence of active pulmonary tuberculosis, confesses "wholesome respect for the danger." (The Modern Treatment of Syphilis, Springfield Ill., Charles C. Thomas, 1933, p. 214).

When the tuberculosis is quiescent, a course of mercury or bismuth compounds in about half the usual dose may be given. This will prevent a possible Jarisch-Herxheimer reaction. After a short rest a course of neoarsphenamine in doses of from 0.15 to 0.45 Gm intravenously every fifth day may be tried. In addition to questioning the patient about any illness or distress following the previous injection, and examining the urine for albumin and casts and the skin of the patient for any itching eruption, one should take the patient's temperature before each injection and none should be given if it is above normal. The course of neoarsphenamine should be followed immediately by a course of mercury or bismuth compounds. After this a rest period should be allowed. Combined courses of mercury or bismuth compounds with neoarsphenamine are not advisable.

Arrested tuberculosis is not a contraindication for antisyphilitic treatment, except that iodine should be avoided or used only with great caution in cases of fibroid tuberculosis. The patient should be regarded as having decreased resistance. The cardinal principle of the treatment of syphilis is that the treatment must stimulate, not depress, the patient's resistance. All drugs should be given in moderate dosage.

Tuberculosis of the suprarenal gland is a definite contraindication to the use of arsphenamine. Tuberculous involvement of the kidneys or liver may render antisyphilitic treatment very difficult. Lymph gland tuberculosis permits fairly active treatment of syphilis. Schamberg and Wright mention the frequent occurrence in Negroes of large glands that diminish to some extent under antisyphilitic treatment but do not subside entirely. (The Treatment of Syphilis New York, D. Appleton & Co., 1932, p. 600).

Skin tuberculosis, at least lupus vulgaris tuberculosis verruosa cutis and the tuberculides often improve on the moderate use of mercury or bismuth compounds or neoarsphenamine. The therapeutic test is therefore of little value to differentiate them from the syphilis.

FUNCTIONAL TEST OF EFFICIENCY OF CIRCULATION

To the Editor—In Queries and Minor Notes in THE JOURNAL June 6, 1931 the injection of saline solution intracutaneously for determining the efficiency of the circulation was described. I should like to have the explanation of why the wheals disappear more rapidly in the area where the circulation is poor or below the point of rupture or obstruction kindly omit name and address.

M D District of Columbia

ANSWER—It is well known that when the circulation to an extremity is diminished, deficient or suddenly cut off there develops an anoxemia in the affected part producing an increase of salt concentration together with a relative increase in acidity. These two factors greatly increase absorbability of injected fluids especially water and saline solution. For this reason it is apparent that an intracutaneous injection of physiologic solu-

tion of sodium chloride into wheals will be absorbed rapidly, depending on the degree of circulatory impairment. The normal absorption rate should be between forty and sixty minutes. In certain circulatory disturbances, especially thrombo-angitis obliterans, the rate of absorption may be as rapid as five or six minutes, and in sudden vascular occlusion or rupture of a large artery the disappearance of the wheal is likewise rapid.

FOUL BREATH

To the Editor—Because of the fact that (1) hyperacetoneuria as in diabetic acidosis produces an acetone breath, (2) hyperuremia as in uremia produces a "urea breath" and (3) hyperalcoholemia produces an alcoholic breath the following questions have occurred to me that you may be able to answer: 1. Is it possible that many of the cases of so-called halitosis exist because of certain foul-smelling substances accumulating in the blood that are volatile and of unknown chemical composition? 2. Has any one thus far been able to elaborate any apparatus by which the degree of odor can be measured? 3. Is there any such thing as an "odorimeter" that could be used to correlate the degree of odor to the breath with the extent of such similar offending odors or volatile substances in the blood? 4. It has been my experience that many cases difficult to diagnose, many cases included in the classifications of psychoneuroses, hysteria, epilepsy and neurasthenia or those generally presenting bizarre or physically unexplainable symptoms frequently show an offensive halitosis as the only outstanding objective sign. Most of these cases have been treated for this symptom unsuccessfully in that the halitosis arose from some nasopharyngeal, gastro-intestinal, oral, dental or upper respiratory changes. Many of these patients have had repeated and thorough examinations of every sort and in the hands of the leading experts in the various specialties but still have (a) their symptoms and (b) their foul breath. Has it even been suggested that some of these poorly understood conditions might arise from the accumulation of unrecognizable (chemically) volatile foul-smelling waste products in the blood which in turn explains the foul breath? 5. Has it been mentioned in the literature of epilepsy that the foulness of the breath runs parallel to the attacks? I would appreciate the answers to these questions and also your opinion as to whether or not this question is one that can be studied under present day laboratory facilities and whether in your opinion the theory is a feasible one or was it thrown by the wayside years ago by ancient clinicians?

WALTER M. BARTLETT, M.D. Greenwich Conn.

ANSWER—It must be conceded that there are patients whose breath does have an unpleasant odor yet whose examination fails to reveal a good explanation. It may be possible, as suggested in question 1 and 3, that this is due to the presence in the expired air of volatile chemical compounds as yet unidentified. Chemists in the perfume industry make use of an apparatus for measuring odors. Possibly such an apparatus could be modified and utilized for study of the odors of the breath, and such a study might provide some interesting results.

The foul breath of the epileptic patient has been referred to in the literature, but it does not appear that definite conclusions can be reached as to a relationship between the foulness of the breath and the occurrence of attacks.

CORNEAL ULCERS

To the Editor—A boy, aged 9 years, has had repeated corneal ulcers since the age of 18 months. The attending ophthalmologist tells me that the ulcers are always superficial, never leave any opacity and always heal in from ten days to two weeks. The child has never gone more than six months without some eye trouble of this kind. The mother tells me that the child's eyes are always worse in the spring. Even while the eyes are normal strong light seems to hurt them. The child has also a refractive error which has been corrected. He has complained some of headache in the past six months. He has been on a good diet, taking cod liver oil and has a nap every day. His habits are good. There is a history of tuberculosis in the grandfather and grandmother both dying from this cause but no exposure. He has had fair general health. He was a full term baby, normal at birth and the delivery was normal. He had measles at 7 years of age, whooping cough at 3 and chickenpox at 2. His tonsils and adenoids were removed at 5 years of age. His developmental history is normal. His father and mother are both living and well. He has a sister aged 8 living and well. His physical examination is essentially negative except for carious teeth. His weight is 40 pounds (18 Kg) and he is 44½ inches (112 cm) tall. Examination of the urine is negative. The Wassermann reaction is negative. Tuberculin reactions (intradermal) have been repeatedly negative in dilutions of from 0.1 to 10 mg. The blood count reveals red blood cells 4,120,000 and hemoglobin 88 per cent. He is alert, bright and cooperative but is in only the first grade of school. He has been out so much I should like to have some suggestion as to the etiology of this condition. I forgot to mention that all sinuses are negative to roentgen examination by a competent man. I should also like some references on the recurrent type of corneal ulcer as seen in the child, preferring pediatric literature rather than from the standpoint of the eye, ear, nose and throat man because I am interested chiefly in the etiology of this condition.

M. C. CARLISLE, M.D. Waco Texas

ANSWER—A great diversity of opinion exists as to the etiology of recurring corneal ulcers in infancy and childhood. The condition is most commonly observed between the ages of 2 and 12 years. Infants and children who have repeated cor-

neal ulcers are also frequently affected with rhinitis, eczema of the scalp and face, hypertrophied tonsils and adenoids and general glandular enlargement. Many manifest the symptoms of the exudative diathesis, as described by Czerny. Early pathologic changes are to be found in the superficial layers of the substantia propria, before the epithelium and Bowman's membrane are affected. The epithelium is soon found to be raised from Bowman's membrane, and leukocytes, some lymphocytes and fixed corneal cells are found between the layers of the cornea nearest the ulcer. The symptoms of intense photophobia blepharospasm and profuse lacrimation are not proportionate to the corneal involvement.

Some authors believe that the disorder is on a neuropathic basis, induced by auto-intoxication. Not all individuals are equally susceptible, those having a scrofulous, exudative or lymphatic diathesis being most liable to show the condition. Others believe that the lowering of body resistance following infectious diseases, chronic illness and malnutrition is the predisposing factor. Most of the children reported suffering with this condition have been well nourished. The affliction has been associated with acne rosacea in adults, though this is rare in children.

The preponderance of opinion seems to base the occurrence of the ulcers on a tuberculous etiology. Whether due to the tubercle bacilli, to their toxins, or to other causes has not been established. The tuberculin skin reactions are strongly positive in as high as 90 per cent of infants and children having corneal ulcers. Those who consider the disease a manifestation of a hypersensitiveness of the patient to tuberculin recommend a desensitization of these children as a therapeutic measure.

The fact that the mother states that the condition is always worse in the spring might lead one to think of a vernal catarrh. This disease is chiefly a disturbance of the conjunctiva characterized by pale elevations, especially on the conjunctiva of the lid. The process rarely involves the cornea, though in severe cases ulcers may occur and produce opacities. This condition is more to be differentiated from trachoma than from phlyctenular conjunctivitis or keratitis. Vernal catarrh may recur each spring for years, and it eventually disappears.

INCUBATION PERIOD AND TREATMENT OF GONORRHEA

To the Editor—What is the outside period of incubation in gonorrhea and in syphilis? What is the usual time under reasonably good treatment, for the cure of an acute case of gonorrhea in a girl of 19? Please omit name.

M. D. California

ANSWER—The period of incubation of gonorrhea is seldom over a week, although a female patient may not be distressed by symptoms until more time has elapsed. In fact, some patients with rather marked infection are comfortable throughout. In practice, if infection is not evident by the eighth day on pelvic examination there is small likelihood of the trouble appearing at a later date.

Although, theoretically, syphilis has been said to have a possible period of incubation of as much as three months, a person who develops no lesions within four or five weeks is relatively safe.

Acute gonorrhea of the external genitalia should under average conditions cause no discomfort after three or four weeks. A latent infection, with a possibility of transmission on sexual intercourse, usually persists for some months.

RESISTANT URTICARIA

To the Editor—A query by M. D. Washington (*THE JOURNAL* April 21, p. 1325) asking for information regarding resistant urticaria interested me because of many similar cases in my practice. There is found in every one of the resistant cases a very low response to the Van Slyke test some of them as low as 32. The patients all recovered after the figure had been raised above 65. The extreme acidity of the blood was evidently the exciting cause in these cases. To raise the alkaline content of the blood by the administration of alkalis brings only transient relief. When raised by diet the result is permanent. This information is offered for what it may be worth.

Illinois January Examination

Mr. Eugene R. Schwartz, superintendent of registration, Illinois Department of Registration and Education, reports the written examination held in Chicago, Jan. 23-25, 1934. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Fifty-four candidates were examined, 47 of whom passed and 7 failed. The following schools were represented:

Book Notices

Human Embryology and Morphology By Sir Arthur Keith M.D. F.R.S. LL.D. Master of the Buckton Browne Research Firm Fifth edition. Cloth Price \$10 Pp 558 with 535 illustrations. Baltimore William Wood & Company 1933

As the title indicates this book reviews the evolution of man from the embryologic and comparative anatomic aspects. In the preface the author says 'Throughout the text I have striven to keep in mind that I am writing, not for professional embryologists and anatomists, but for men who are to be practical physicians and surgeons.' In the first edition (1901) he kept as closely as possible to what is essential for the understanding of human anatomy and fully capitalized the teratologic evidence. The pleasing style of the original lectures has been preserved as in succeeding editions the field has been more completely covered. The present edition exceeds the fourth by about 13 per cent, the chief additions are new illustrations, a chapter on experimental embryology, and 'notes' that call attention to recent work and give literature references. The illustrations are for the most part diagrams such as a clever draftsman could draw on a blackboard. They have the inaccuracies of such sketches and in some cases in which the illustrations have been copied there are errors inexcusable in a published work. To any one who has embryologic material to study they are wholly inadequate however the book was written for students who have no opportunities for laboratory work. Many of the original diagrams are packed with information and are highly illuminating. The adult anatomy of certain organs such as the brain the intestine and the urogenital apparatus can be understood only in the light of their developmental history. These are presented in especial detail. More space is devoted to the nervous system than to general embryology and early development together and the account is clear and particularly helpful for an understanding of the anatomy of the brain. The value of the comparative point of view is abundantly demonstrated. There is a good account of the development of the mesenteries and of other peritoneal relations. While theoretical considerations such as those concerning the metamorphosis of the head and limbs are not accepted by all morphologists, they are supported by evidence, they help the student to understand complex relations and they are accordingly justified in a textbook. The index is adequate, the typography excellent.

Die Tonuskrankheiten des Herzens und der Gefässe ihre Biologie und Therapie Von Prof. Dr. J. Pal Paper Price 18 marks Pp 228 with 20 illustrations. Vienna Julius Springer 1934

This monograph on the disturbances of vascular tension is by one of the best known continental contributors to the literature on this subject. Throughout the discussion a credible attempt is made to keep the physiologic mechanisms and processes constantly correlated with the clinical phenomena. A clear and concise review of the biologic aspects of muscle tonus is followed by a far fuller consideration of the normal and pathologic biology of the heart, arteries and capillaries. More than half of the monograph is devoted to the clinical disturbances of vascular tension hypertensive disease and hypotension. The discussion of the etiology and pathogenesis of hypertensive disease is unfortunately inadequate. There is no consideration of the newer American work on these fascinating and vitally important aspects of the problem. Pal considers generalized hypertension to be of toxogenic origin, the emotional constitutional and hereditary factors are given but scant attention. There is an attempt to distinguish between 'primary hypertension' and 'toxogenic hypertension,' particularly in considering the effects of hypertensive disease on the kidneys, such divisions are arbitrary and tend to confuse rather than clarify the issue. Though the illustrations are not numerous, they are carefully chosen and well executed. Of especial value are several fine photomicrographs showing arterial changes. The thoracic roentgenograms intended to illustrate changes in cardiac contour and size appear to be less wisely chosen, for several are exaggerated examples. The bibliography is almost wholly continental, particularly German and Austrian. There is an unfortunate lack of appreciation of the significant advances made elsewhere, for example, the discussion on angina pectoris includes no mention of the work of Sir Thomas Lewis and many others on myocardial ischemia or histanoxia. In many respects the monograph is a review of the author's previously reported work with fully three pages of the bibliography devoted to his own publications. Reference to American literature is almost wholly lacking. The book is printed on good quality paper, but the paper cover is of the flimsiest grade. The book has its greatest value as a review of the work and views of the author, who has contributed much that is important in the development of knowledge concerning that dread triad cardiovascular-renal disease. The monograph should be of considerable interest to those who are making a special study of these problems, although it contains little that has not already been published. Students and physicians without special interests in this field will find ample material and ideas in the several American monographs on the subject.

The Queen Charlotte's Text Book of Obstetrics By the Following Members of the Staff of the Hospital. Aleck W. Bourne M.B. FRCS FCOG Obstetric Surgeon to Outpatients St. Mary's Hospital. Trevor B. Davies M.D. FRCS FCOG Gynaecological Surgeons Hospital for Women. Soho L. Carnac Rivett M.C. FRCS MCOG Surgeon Chelsea Hospital for Women. L. C. Phillips M.S. FRCS MCOG Assistant Surgeon Hospital for Women. Soho C. S. Lane Roberts M.S. FRCS MCOG Obstetric Surgeon Royal Northern Hospital and Leslie H. Williams M.D. M.S. FRCS Obstetric Surgeon to Outpatients St. Mary's Hospital. Third edition. Cloth Price \$6 Pp 679 with 301 illustrations. Baltimore William Wood & Company 1934

The first two editions of this book (1927 and 1930) bore the title 'The Queen Charlotte's Practice of Obstetrics.' In the present edition Leslie Williams has replaced J. B. Banister as one of the six authors. In general, the book is almost identical with the previous two editions except for the addition of a few new illustrations and revisions of a few chapters. The opening of an isolation block in 1930 for cases of puerperal infection has afforded the authors a wealth of experience in the diagnosis, care and treatment of this disease. In spite of the added experience it is still the practice at Queen Charlotte's Hospital to evacuate the uterus in cases of febrile abortion and in some instances to instil glycerin into the uterine cavity. Likewise in cases of puerperal sepsis with blood stream infections, the authors recommend instillation of glycerin into the uterus or uterine irrigations. Eclampsia is treated conservatively, but veratrine is advocated for the reduction of blood pressure. This drug usually produces a sharp drop in the blood pressure but at best this is temporary and it may prove harmful. In the treatment of placenta praevia the authors follow the present

general trend of performing a cesarean section for a certain number of these cases. They encountered no maternal death in their series of forty-nine cesarean sections for this complication. In the first edition the authors reported a series of fifty-four cesarean sections with three deaths (5.5 per cent). For the induction of labor by rupture of the membranes the statement is made that an anesthetic is usually required for primiparas, but this is contrary to general experience. The authors still prefer the classic cesarean section, as evidenced by the fact that they devote nine and a half pages to the description of this operation and only half a page to the cervical cesarean section. Even in 1934 the authors still quote Kerr and Holland's 1921 figures to show a mortality of 7 per cent for 4,160 classic operations and a death rate of 15 per cent for thirty-three cases of lower segment operations performed in the British Isles. The high death rate for the thirty-three low operations is undoubtedly due to the fact that these were the first few operations performed by British operators, who were slow to take up this operation (except Munro Kerr). The authors should compare their series of classic operations with the report by Greenhill (*Am J Obst & Gynec* 19 613 [May] 1930) for the Chicago Lying-in Hospitals 874 low, cervical operations, with a maternal mortality rate of 1.26 per cent. In spite of the fact that in the review of the first edition (*THE JOURNAL*, Sept 24, 1927, p 1084) attention was called to a number of De Lee's illustrations that were copied without mention being made of the source, the same illustrations appear in the present edition with no indication of their origin. The appearance of the third edition testifies that the book is undoubtedly popular in the British Isles.

Patogenesi e terapia della sindrome di Morgagni Adams Stokes. Dal Prof. Luigi Condorelli aiuto della II clinica medica della r Università di Napoli. Paper. Price 30 lire. Pp 107 with 59 illustrations. Naples. V Idelson 1933.

Expressing the hope that the work may be of use to general practitioners as well as to cardiologists the author introduces this small volume by reminding physicians that the treatment of heart block is frequently groping for a drug valuable to one patient with the Adams-Stokes syndrome may be dangerous to another, since the pathogenesis of the syncopal attacks is notoriously diverse from subject to subject and even from time to time in the same individual. The discussion of pathogenesis occupies seventy-four of the eighty-one pages of the text. By abundant reference to literature and analysis of much of the author's own clinical and graphic material, the modern concepts of the pathogenesis of the syndrome are clearly told. Adams-Stokes attacks occurring during partial heart block and those during complete auriculoventricular dissociation are considered separately. In the section on complete heart block, the author reports one example of a hitherto undescribed type of peculiar, recurrent, ventricular fibrillation and gives full clinical and pathologic details. The part of the book devoted to treatment is small, but the suggestions are succinctly put and well worth attention. As a prelude to treatment, a series of functional and pharmacologic tests is advised for the purpose of establishing the pathogenesis of the attacks. Because electrocardiographic examination is foremost among these preliminaries, it might be inferred that Adams-Stokes attacks can perhaps be properly treated only by those practitioners who have such mechanical aids constantly at their disposal. That the author is himself equipped to gather and analyze important data by less complicated means is quite evident. The detailed instructions for treating paroxysms of ventricular fibrillation and associated syncope for example, are particularly practical and surprisingly optimistic in view of the hopeless prognosis so universally assigned the condition. The less sensational but more common disturbances of conduction and their treatment by atropine, epinephrine, digitalis, barium chloride, the purine bases, stimulants, sedatives and other measures are also outlined. One realizes with a feeling of regret that the language in which it is written will prevent the wide dissemination which this monograph deserves. It is a logical sequel to the author's recent '*Die Ernährung des Herzens und die Folgen ihrer Störung*' (Dresden and Leipzig: Theodore Steinkopff 1932) and as such will be missed by those without a knowledge of Italian. We are at least, indebted to the latter tongue for

the paradox of a language, unable to render the equivalent of "reizbildung" or "kupplung" but offering, with inimitable onomatopoeia a description of the auscultatory signs of ventricular fibrillation in which we are told that the sound is "come un fruscio di ali." There is an index to subject matter and to authors. The bibliography, listing 211 works, is purposely limited to those actually cited in the text.

13 let nauchnoy meditsiny na Severnom Kavkaze 1920-1933. Otvetsenny redaktor I. L. Benkovich [Thirteen Years of Scientific Medicine in North Caucasus]. Cloth. Pp 244 with illustrations. Rostov na Don. Izdatel'stvo 'Severny Kavkaz' 1934.

The volume is the official publication of the Scientific Medical Soviet of North Caucasus. It embraces the accomplishments of the scientific and medical activity for the period between 1920 and 1933. In the introductory statement by the secretary of the organization one learns that North Caucasus constituting under the czars one of the backward, neglected and oppressed "foreign territories," has been converted under the new regime into a flowering spot of culture and science. Combining as it does about a hundred related nationalities it has become one of the frontier strongholds of the Soviet Union. The scientific and investigative work of the newly developed network of scientific institutes (twenty-two in all) was directed by the party and the government toward the solution of definite problems. A single plan of research to constitute an organic part of the entire plan of Soviet Russia was worked out. The possibility of planned scientific work within the conditions of socialist reconstruction has been answered in the positive. Its advantages are the avoidance of overlapping, the focusing of attention on the problems of the leading industries and obligatory attention to the specific problems of a given territory and the various nationalities residing there. The volume contains twenty-four papers dealing with original research and studies in the various branches of scientific and practical medicine. Endogenous diseases of this cattle grazing country such as echinococcosis and brucellosis, were made a subject of a special study. Notable advances were made in the reduction of maternal and infant mortality and in the study of children and adolescents. The necessity of carrying into scientific and practical work the philosophy of dialectic materialism of Marx-Lenin is heavily underscored. Judged by our standards the plan is comprehensive and the results achieved notable. The papers represent creditable work of a high order. Particularly interesting are the physiologic studies of the subcortical ganglions, the anatomic studies of the circulation of parenchymatous organs by means of an original method of colored celluloid corrosion preparations. Its inventor, Dr. Golubev established the existence of a closed vascular circulation within the spleen. Reconstructive surgery, transplantation of organs, and blood vessel surgery are among other subjects reported. The paper and print are a vast improvement on the former consignments from the Union of Socialist Soviet Republics.

Pathologie de l'appareil urinaire (reins, vessie). Par Pasteur Vallery Radot, professeur agrégé à la Faculté de médecine de Paris. Paper. Price 22 francs. Pp 201 with 10 illustrations. Paris: Masson & Cie 1933.

Masson et Cie, Parisian editors, under the direction of Dr. A. Sezary, are publishers of several elementary volumes on medical subjects, which are similar to our American compendiums. The volume under review is a member of this series. Pasteur Vallery-Radot overcame a difficult problem when he compiled this small elementary volume on the diseases of the kidney and bladder. It was planned primarily for students, especially beginners in the special field of urology, and likewise to remind the general practitioner of those basal facts which he must remember in establishing an accurate diagnosis of disorders of the kidneys and bladder. Many valuable and helpful facts are arranged systematically. This volume is paper bound and is divided into four chapters dealing with symptoms, physical and special examinations, and brief descriptions of renal and bladder diseases. The first chapter deals with a description of those symptoms complained of by the patient, such as hematuria, albuminuria, pyuria, polyuria and oliguria. The second chapter deals with the physical examination and includes cystoscopy, ureteral catheterization, radiography, urinalysis, test of renal function, and pain radiation.

The final two chapters describe the principal disorders of the kidneys and bladder, separately considered. The nephritides are given considerable space (seventy pages), while the surgical diseases are handled more briefly. Brief accounts of renal disorders include amyloid kidneys, pyelonephritis, perinephritis, lithiasis, cancer and tuberculosis, hydronephrosis, polycystic kidney and nephroptosis. Inflammations, stones and tumors of the bladder are considered. This work gives the elementary clinical and pathologic facts and can be recommended to those interested in a short clear reminder. It should be commended for its accuracy and brevity in the presentation of a large and difficult subject.

The Surgery of the Sympathetic Nervous System By George E. Gask, CMG DSO FRCS Professor of Surgery University of London and J. Paterson Ross, MS FRCS Reader in Surgery University of London. Cloth Price \$4.15 Pp 163 with 43 illustrations. Baltimore: William Wood & Company 1934.

The authors have presented a brief survey of the subject of surgery of the sympathetic nervous system as it exists to date. The monograph contains no new contributions to any phase of the subject. It is divided into four chapters. The first deals with the anatomy and physiology of the sympathetic nervous system. The anatomy is discussed in a clear and concise, although brief, manner. The discussion of physiology is too cursory to be of value either to the surgeon or to one seeking specific information concerning the function of this system. This phase has, however, been somewhat further elucidated in the discussion of the various clinical conditions. The second chapter is concerned with disorders of circulation. Various tests of the functional capacity of the vasomotor mechanisms and their clinical significance are discussed. The various operative procedures are then considered along with a discussion of their clinical application to circulatory disturbances. In chapter III the application of sympathectomy to disorders of the abdominal viscera is discussed, and in the last chapter the utilization of this surgical procedure for the relief of pain. For the most part the text is quite clear, but at times, particularly when dealing with physiologic matters, it becomes confused, even contradictory, as on page 49, where one reads that excision of the diseased proximal portions of an artery may be more efficacious in producing dilatation of the peripheral vessels than simple ligation, because the vasoconstrictor impulses have been prevented from reaching the peripheral vessels. This is directly contradictory to all anatomic and physiologic knowledge concerning the pathway of constrictor impulses, which the authors have been at some pains to elucidate only a few pages before (p. 43) and to their further discussion (p. 50), in which they bring out that the effect is probably due to the interruption of afferent impulses of a pressor nature. This is the most striking example of rather confused thinking, which is to be found also in a number of other places. On the whole the book is an acceptable introduction to the field it considers, but modern surgery of the sympathetic nervous system is deserving of much more thorough adequate treatment. The publishers are to be congratulated on the clear pleasing typography and the illustrations, which are all beautifully reproduced.

Psychiatrische Vorlesungen für Ärzte Von Prof. Dr. Kurt Schneider, Direktor des klinischen Instituts der Deutschen Forschungsanstalt für Psychiatrie (Kaiser Wilhelm Institut) in München. Boards. Price 3.40 marks. Pp 140. Leipzig: Georg Thieme 1934.

This little book represents a type of publication found often in Germany but seldom in this country—a handbook of psychiatry for the general practitioner, in which the author attempts to give the physician an outline of those conditions likely to be encountered in general practice rather than to compile a handbook of the psychoses. The point of view stresses the organic background of many of the mental conditions, although the volume itself begins with a study of the two most important functional psychoses, schizophrenia and cyclothymia. These two disorders are briefly studied and their therapy is emphasized. A good discussion of the psychopathic personalities and of neurasthenia is included since these conditions are much more important to the general practitioner than are psychoses, the book deals with them more fully.

Separate chapters are devoted to children's abnormalities and to suicide, two psychiatric entities of considerable importance but usually dealt with as symptoms of major mental disturbances. It must be pointed out that the point of view of the chapter on child guidance is old fashioned and does not fit in with the mental hygiene practices of this country. The whole book must be looked on as a superficial approach to the problems of psychiatry. The entities dealt with are handled in a sketchy fashion, and the practitioner who really wanted to know about these disorders would scarcely find much in this book that would be of value to him. No new views are brought out, and while the style is easy and interesting and the terminology is kept simplified, there is no glossary for the technical terms that must necessarily creep in whenever a specialty is being presented for the practitioner. It is questionable whether this book would be of much help to the American practitioner since the courses in psychiatry now being given in medical colleges are sufficiently complete to render a volume of this kind unnecessary.

Die geburtshilflichen Operationen Ihre Ausführung und Anwendung Ein Lehrbuch für Studierende und Gebrauchsbuch für Ärzte Von Prof. Dr. med. Heinrich Marilius, Direktor der Universitäts-Frauenklinik, Göttingen. Paper. Price 12.50 marks. Pp 256 with 276 illustrations. Leipzig: Georg Thieme 1934.

The object of this book is to describe in a concise manner the technic of obstetric operations without quoting statistics or bibliography. After a short description of the genital tract and fetus the author discusses the various mechanisms of labor and in the following chapters covers the technic of forceps delivery, operations employed in breech presentation, versions, embryotomy, episiotomy, vaginal hysterotomy and abdominal cesarean section. A short chapter is devoted to the treatment of abortion. The text is written clearly and to the point; the handy volume is profusely illustrated, excellent drawings, reproductions of photographs and colored pictures speak for themselves, the print and paper leave nothing to be desired. Seldom does one find a book that is so full of valuable information. The publication can be heartily recommended to every practitioner of medicine.

The Evolution of the Vertebral Column. A Contribution to the Study of Vertebrate Phylogeny By H. F. Gadow, MA, PhD, FRSE, Edited by J. F. Gaskell and H. L. H. Green. Cloth. Price \$6.75. Pp 356 with 123 illustrations. Cambridge: The University Press, New York: The Macmillan Company 1933.

The problem of the evolution of the vertebrae has been one of the author's principal interests throughout a period of forty years. The book is a report of investigations and thought on the morphologic problems of the vertebrate phylum. It contains research on various lines of development of the vertebrae which serve as a guide to the morphologic scheme of vertebrate evolution. The sudden death of the author left the manuscript unfinished—a task that was performed by the editors. Certain chapters are therefore incomplete. The author emphasizes that all vertebrates possess a vertebral column, the evolution of which passes through several successive stages, their phylogenic causal features being on the whole faithfully repeated by the developing individual; that is, the phylogenic changes produced during evolution by alteration of environment are simulated by ontogenic changes that take place during the development of the individual. The material for building the spinal column develops from the notochord, which is of endodermal origin, and from muscular and connective mesodermal tissue, which surrounds the chorda, furnishes the walls of the spinal canal and further extends as septums through most parts of the body. The principal tendencies in evolution of a physiologically adequate axial skeleton reveals the successive, repeated supercession or substitution of the original central axial material by sheaths or mantles that are placed more peripherally. The mammalian vertebral column has reached the highest stage morphologically, the tendency initiated by the reptiles of forming highly efficient bony vertebrae by fewer ossifying units at the expense of others having reached a perfection greater than in birds. This book should be of interest to the students of comparative anatomy but does not contain information of practical value to the general practicing physician or surgeon.

L'artériectomie dans les artérites oblitérantes Étude expérimentale et thérapeutique. Par René Leriche professeur à la Faculté de médecine de Lyon et Pierre Stricker. Paper. Price 40 francs. Pp 197 with 78 illustrations. Par Masson & Cie 1933.

This summarizes work done by one of the pioneers in the surgical treatment of peripheral vascular lesions. It includes considerable work by his associates but represents the Leriche school of experience. The book contains experimental research on arteriectomy in the treatment of certain obliterating arteritides. There is a discussion of the pathologic anatomy of obliterating arteritides and explanations of the physiologic and pathologic aspects of the subjects. The author outlines the clinical indications for arteriectomy, including traumatic obliterations, monoarteritis of undeterminable origin and embolic obliteration of the arteries. He next discusses primary arteriectomy in wounds and contusions and spontaneous rupture, arteriectomy in obliterating arteritis and their arteriographic indications. The illustrations include diagrams reproductions of photographs and photomicrographs. There is a bibliography of the articles written by French authorities.

Operative Gynecology By Dr H v Pehnm Privy Counsellor Professor of Obstetrics and Gynecology and Dr I Amreich Privatdozent for Obstetrics and Gynecology of the University Vienna. In two volumes. With an introduction to the edition in English by George Cellhorn M.D. Professor of Clinical Obstetrics and Gynecology Washington University School of Medicine St Louis Mo. Authorized translation made by I Kraeger Ferguson M.D. Associate in Surgery University of Pennsylvania. Cloth. Price \$2.50 per set. Pp 779 with 467 illustrations. Philadelphia C London I B Lippincott Company 1934.

This monumental work is divided into three parts. The first part, on general principles, is devoted to a discussion of sepsis and antiseptics anesthesia preoperative and postoperative treatment, postoperative complications and their therapy, hemorrhage and hemostasis and methods of opening the abdomen. In the second part the surgical anatomy of the female pelvis is described. It is recognized today, more than ever before that a well developed anatomic background is a requisite for a successful operative experience. In this book the pelvic connective tissue, ureters arteries veins and lymphatics of the genital system and rectum and the nerve supply are described in greater detail than can be found in any other book of this kind. The authors own dissections are reproduced in pictures of startling perfection. The colored full page illustrations, accompanied by extensive explanatory legends, come close to actual work on the cadaver. The part on operative technic follows that on anatomy. It starts with a graphic description of the radical abdominal and vaginal hysterectomy. The flowing style is as enjoyable and instructive as the pictorial accompaniment. All the other operations are presented with the same wealth of detail, the surgical procedures being described step by step. Indications for each operation based on contemporary literature and the authors' own experiences are discussed at length, thus contributing to perfection of surgical judgment of the reader. Selectiveness of tried operative methods cannot be considered as a shortcoming. Of course, there occur minor differences in the approach to certain problems as compared to ideas prevalent in America. For instance, discussion of ethylene anesthesia has been omitted. Jansky's and the international classification of blood grouping and paraffin (Percy) method of blood transfusion are not described. The use of dextrose injections in postoperative treatment is not mentioned. The excellent quality of paper and the large type contribute to the reader's enjoyment. All in all, this treatise represents an unusual combination of art and science that cannot be too highly recommended.

The Cancer Problem and Its Solution By Hastings Gifford FRCS. Cloth. Price 2s 6d. Pp 59. London H K Lewis & Company Ltd 1934.

In a highly interesting and purely philosophical discussion, the author concludes that cancer is a national punishment or scourge that affects all civilized nations in which there is an ever increasing growth of national degeneracy. According to his theory there is a definite and direct connection between cancer of the individual and the decadence of the race. He further believes that the behavior of mankind is so completely irrational that the present generation is in the hands of an uncontrollable destiny and that like all other peoples in history

we are fated to become nationally senile to complete our cycle and to die as other nations have died, that some great calamity or terrible plague is needed to rouse us out of our apathy, and that cancer is the scourge that has been visited on us to accomplish this deed. Four causes of predisposition to cancer are cited: senescence, disuse, excessive stimulation and heredity. The author especially stresses the neglect of work or exercise of function as leading to premature degeneration of the intestinal tract, and that out of this degeneration cancer finds its congenial soil. As the author himself points out, the scientific mind, accustomed to precise clinical and laboratory data will be interested in but not convinced by his thesis. He believes that there are already adequate data for the solution of the cancer problem, that such data merely require a proper correlation to supply the solution, and that we need not concern ourselves with the addition of new facts. This may be true, but it is impossible to prove and appears a rather dangerous position to adopt, and certainly one that might greatly hinder or make impossible any further progress in cancer research. One cannot help but be struck with the simplicity of the solution of so complex a problem as the cause and prevention of cancer that is presented by the author, a simplicity that naturally arouses a certain degree of skepticism. It cannot be denied however that the ultimate solution of the cancer problem may lack the complexity which we suspect. The author presents his point of view in an interesting manner and attractive style. It is well worth reading, particularly because of the broad and social point of view that it presents and on account of its interesting philosophical speculation.

Gelenksteifen und Gelenkplastik Von Professor Dr Erwin Payr, Gehilmer Medizinalrat, Direktor der chirurgischen Universitätsklinik Leipzig, Teil I. Pathologische Biologie der Gelenke. Pathogenese und pathologische Anatomie der Ankylosen. Klinik Diagnostik und Anzeigstellung. Paper. Price 120 marks. Pp 880 with 240 illustrations. Berlin Julius Springer 1934.

The author of this book is well known and his name commands the highest respect and closest attention. The subject matter is divided into the pathology, biology and comparative anatomy. The manuscript is written with the usual German accuracy and verbosity. At times one finds twenty-five large pages of closely printed manuscript without an illustration. The book contains reproductions of photographs, roentgenograms, gross and microscopic sections and diagrams. One anticipates many redeeming features in the second volume and will be sadly disappointed if the surgical treatment is not presented in an admirable manner by manuscript and illustrations. The price of this paper bound volume is a glaring overcharge.

Keeping a Sound Mind By John J B Morgan Professor of Psychology Northwestern University. Cloth. Price \$2. Pp 440 with one illustration. New York Macmillan Company 1934.

This book is offered for the dual purpose of serving as a textbook in courses of mental hygiene and as a guide to enable the college student to apply the principles of mental health to himself. The two purposes can hardly be competently dealt with in one book and in the present volume, it would seem that the author has compiled a work better fitted for self guidance than for teaching. The mental hygiene principles are well laid out. The chapters are systematic and the points brought out in each are interesting and graphically presented by means of short illustrative situations and admonitory disquisitions. Most of the material is taken directly from the literature of mental hygiene although direct quotations are not made and it is so modified that it fits systematically into chapters with such descriptive titles as 'Mental Conflicts,' 'Mastery of Fear and Counteracting Defects.' Since the mental hygiene movement is so largely made up of freudian and adlerian doctrines, these predominate in the present volume, though the author has also drawn much interesting material from the field of experimental psychology. When reading a book of this sort, the question arises whether mental conditions are not overemphasized in the patient's mind to the extent that efforts which he makes to correct an existing or supposed disorder may be detrimental to him and the hortatory method of administering psychotherapy is a questionable one in cases in which there is real pathologic change. On the other hand this book is well written and it adheres to the beliefs current

in its field so closely that it cannot be severely criticized. However, it is certainly not a scientific textbook and the techniques presented, in some spots, for the purpose of determining mental health cause one to wonder where the author obtained his ideas, but the book will probably be just as useful as the many other works of its ilk.

Le dualisme de la contraction cardiaque. Recherches expérimentales du laboratoire de thérapeutique de l'Université de Liège. Par F. Henrijean. Docteur Honoris causa des Universités de Paris de Lyon de Toulouse etc. Paper. Price 50 francs. 1 p. 350 with 97 illustrations. Paris: Masson & Cie 1933.

This monograph, which is published posthumously is the "scientific testament" of the thirty years work which Henrijean put into the study of cardiac contraction. He presents evidence obtained by himself and others to defend the proposition that two systems exist in the heart one essentially excitatory and the other essentially contractile. The QRS complex he ascribes to activity of the former and the T wave to the activity of the latter. In this work the author has gone a long way to reconcile his original contentions with the modern classic concepts. His views as explained in this monograph are somewhat different from those in his monograph published three years before. The complexity of the presentation and the originality of the author's point of view make this work suitable only for the advanced student of cardiology.

Traitement des maladies rhumatismales par la sanocrysin. Par Knud Secher. médecin chef à l'Hôpital de Bispebjerg Copenhague. Second edition. Paper. Pp. 84 with 25 illustrations. Copenhagen. Levin & Munksgaard. Paris: J. B. Baillière et Fils 1933.

This edition records the author's experience in the treatment of rheumatic disease since 1933. He outlines in detail the indications for the control of the condition and dosage of sanocrysin, with a complete discussion of the course of treatment. Gold salt was originally introduced by Møllgaard in 1914 in the treatment of pulmonary tuberculosis. The compound used is sodium thiosulphate and gold, known under the name of sanocrysin. A complete bibliography is given.

Medicolegal

Malpractice Hypodermic Needle Left in Pleural Cavity—Remhold was suffering from acute pneumonia and it became necessary "to perform an operation known as 'tapping the lungs'." Dr. Spencer, using procaine hydrochloride to deaden the pain, operated. He used a syringe carrying a hypodermic needle approximately 23½ inches long. According to the testimony the physician, when he withdrew the syringe from his patient's body, uttered an exclamation of surprise, handed "what looked like a part of the syringe" to the nurse and asked for another one which was given him. The syringe handed to the nurse "looked like the point was broken off" and thereafter the patient had an awful pain in his chest on the inside. An opening was made into the chest and a drainage tube inserted. According to the record the operation was scientifically and properly performed and the wound was sewed up and healed normally. No attempt was made at any time while the patient was in the hospital to remove the needle and apparently he was not notified of its presence. The patient continued to suffer constant pain in his chest, which was so severe on physical exertion as to prevent his doing manual labor. The needle in the left pleural cavity was discovered later by a roentgenographic examination, but an effort made to remove it was abandoned as too greatly endangering the patient's life and it remained in the plaintiff's body at the time of the trial. The patient sued his physician charging negligence and unskillfulness in handling the hypodermic needle inserted into the plaintiff's pleural cavity in such a manner as to allow the needle to become detached from the syringe and negligently and unskillfully leaving the needle in the pleural cavity and in discharging the patient as cured without informing him of his condition. Judgment was given in favor of the plaintiff and the defendant-physician appealed to the Supreme Court of Idaho.

The Supreme Court found that the evidence was adequate to show that the pain suffered by the patient subsequent to the operation resulted from the presence of the hypodermic needle in his chest and diminished the patient's ability to perform manual labor. It held that testimony to show the extent of the pain and its effect on the patient's ability to perform manual labor was properly admitted. There was no such uncertainty as to whether the patient's pain and suffering were caused by the hypodermic needle or by some other cause as to require the jury to guess or conjecture as to its cause. The roentgenograms in the case were properly proved and admitted in evidence. Testimony by the roentgenologist, a physician as to the probable course of events if the needle remained in the patient's body, was properly admitted. The admission of life tables to prove the extent of the patient's future suffering and loss was proper, notwithstanding the fact that there was evidence that the patient had in previous years been injured and had had several operations for varicose veins on one of his legs. No evidence was introduced to show that the injury he had suffered or the operations performed resulted in any impairment of the patient's health likely to diminish the span allotted by the life tables to men of his age. The evidence was sufficient to support the verdict against the defendant-physician and the judgment entered on it. The judgment was therefore affirmed by the Supreme Court.—*Remhold v Spencer (Idaho)*, 26 P. (2d) 796.

Malpractice Alleged Negligence in Treatment of Gunshot Wound—On August 24, McDermott was shot, the bullet passing through the right axillary fold. He was immediately taken to a hospital, where the wound was cleaned and gauze packs were applied in front where the bullet entered and in the back where it passed out. Drs. Lamb and Gray, who were called to treat the patient arrived about an hour after the patient was admitted to the hospital. They found his radial pulse good and no evidence of injury to any nerve trunk. There was no bleeding. They concluded therefore not to probe the wound but to care for the patient and to await developments. His condition remained good until September 3, when it was discovered that a blood clot had formed internally, that the circulation was impaired and that the nerves in the arm did not react properly to tests. A third physician was then called in, and the following morning the three physicians operated. When the blood clots were removed, the vein bled profusely. Its distal end was tied, but its proximal end was not. Bleeding ceased. Thereafter, however, a blood clot formed in the vein, passed into the heart and thence into the lung and thus caused the patient's death.

McDermott's widow sued Drs. Lamb and Gray for malpractice. While the suit was in progress Dr. Gray died and his widow as executrix of his estate was substituted as a party. The complaint as to Dr. Lamb was dismissed by the plaintiff. At the close of the evidence for the plaintiff, the then defendant Dr. Gray's widow requested the court to direct the jury to return a verdict in her favor, but this the court refused to do. A judgment of \$20,000 was entered against her and she appealed to the Supreme Court of Arkansas.

The plaintiff based her action in part on the charge that Dr. Gray was negligent on August 24, when he did not open the wound to determine whether or not the bullet had severed an artery or a vein but she introduced no evidence to support that charge. On the other hand the defendant called five or six physicians who testified that in their opinion it would have been bad practice to go into the wound to determine whether a vein had been severed, probing might puncture the axillary artery, axillary vein or a nerve controlling the arm and the severance of any of them would endanger life and diminish the chance of recovery. The only purpose of entering the wound on August 24 would have been to stop hemorrhage, and since hemorrhage had stopped before Dr. Gray arrived it would have been unreasonable for him to open the wound. It was better for him to await developments, after giving antitoxin. The only expert witness called by the plaintiff did not controvert this testimony.

As further ground for her suit, the plaintiff charged that the defendant was negligent in failing to ligate both ends of the vein during the operation on September 4. All the expert

witnesses agreed that where a vein is recently severed, both ends should be ligated. There was no testimony showing or tending to show that that procedure should be followed where the tissues had sloughed, opening a hole into the vein some days after the original injury, the mishap not being discovered until after internal bleeding had taken place sufficient to form two clots the size of a lemon. Under such circumstances, the medical witnesses agreed, the operating physician should ligate the bleeding end of the vein, but that it was not his duty to ligate the proximal end if it was not bleeding, because of the lapse of time, a blood clot was necessarily present in the non-bleeding proximal end of the vein and the manipulation would be likely to disturb the clot. This testimony, the court thought, was not in conflict with that of the medical expert who testified for the plaintiff, that if a section of the axillary vein had been taken out, both ends should have been ligated, for in this case no part of the vein was removed.

In the absence of expert testimony in support of the plaintiff's theory, the jury should not have been allowed to speculate on whether or not the physicians who were in attendance on the plaintiff's husband followed a proper professional course. The uncontradicted testimony showed that they treated the patient with the degree of skill and learning ordinarily possessed and exercised by members of their profession in good standing in the community, that they used reasonable care in the exercise of their skill while attending him, and that they exercised their best judgment. That is all that the law of Arkansas requires of physicians.

Because the trial court erred in refusing to direct the verdict for the defendant the Supreme Court dismissed the suit—*Gray, Et al v McDermott (Ark)* 64 S W (2d) 94

Workmen's Compensation Acts Paralysis Agitans Following Trauma—On Aug 12 1928 in the course of his employment, Moffett, a strong able bodied man 24 years old, was lifting cases of canned peas. A case weighed 40 pounds, but two cases happened to be stuck together and Moffett unexpectedly encountered a load twice as great. He immediately felt pain in his right side and back at the top of his hip bone, and had to discontinue his work. He was treated by a physician, who diagnosed the case as 'antero posterior lumbago'. On returning to duty the next day, Moffett was assigned to light work. When on that day he visited his physician's office he was more nervous than usual. Within three weeks he had a pronounced tremor in his left foot, which gradually spread to both legs his tongue and his head. Ultimately he became unable to perform his duties with his then employer and found lighter work, which he followed until it became impossible for him to work at all.

Moffett's disability immediately incident to the accident was adjusted by the payment of compensation and hospital expenses, Oct 19, 1928, and the industrial accident board of Montana heard nothing further concerning the case until September 1930. Then Moffett claimed compensation for total disability. The board disallowed his claim and he appealed to the district court, Gallatin County, which ordered the payment of compensation. Moffett's employer and his employer's insurance carrier appealed to the Supreme Court of Montana.

The question for determination, said the Supreme Court, was whether or not the accident was the proximate cause of Moffett's disability. All physicians who testified agreed that he was suffering from Parkinson's disease (paralysis agitans) or the parkinsonian syndrome, commonly known as shaking palsy either of which totally disables its victim and is progressive and incurable. As to its proximate cause however, there was a conflict of medical opinion. Medical science has not definitely determined the cause of Parkinson's disease or of the parkinsonian syndrome in the individual patient, but it follows trauma, infection or emotion, and therefore medical authorities have adopted the theory that it may be caused by any one of those conditions.

In the present case the testimony ruled out emotion and the type of infection which medical experts used principally as the basis of their deductions concerning the causation of the disease. There was no evidence that Moffett ever had encephalitis lethargica (sleeping sickness) or that there had ever been

a case of that disease in the community. If gonococci were present—a conclusion left in doubt by the testimony—it was not shown that they constituted an infection known to be followed by this disease, which ordinarily attacks the aged and but rarely the young. The evidence thus ruled out practically all the theoretical causes except trauma. Dr Kelly testified that in his opinion Moffett's condition "was caused at the time of the injury." Dr Rodes, who thought Moffett was suffering from the parkinsonian syndrome and not from Parkinson's disease, was "inclined to believe or feel that the accident was not the cause." Dr Cooney believed that injury was not the cause. Dr Treacy was of the opinion that the injury did not cause Moffett's condition but that his condition was "almost certainly a result of an infection which resulted in encephalitis lethargica." A report from Dr Bolton surmised that Moffett's condition was "probably due to previous infection." The medical witnesses frankly admitted, however, that they did not know, and that the "authorities" did not know, what causes Parkinson's disease or the parkinsonian syndrome. The statements made by the doctors, said the court, hardly rise to the dignity of expert opinions; they are more in the nature of surmises based on the pathology of the disease than on facts which an attorney would be entitled to include in a hypothetical question propounded in the case. Under all the rules of evidence when an expert witness after answering a hypothetical question, admits that he does not know the answer and that no one in his profession does, the expert's answer should be stricken from the record and wholly disregarded by the trier of the facts. The so-called opinions of the medical experts the Supreme Court concluded were too speculative and conjectural to support the finding of the industrial accident board denying compensation to Moffett.

Moffett produced all the evidence possible. No known authority could furnish positive testimony that would have induced the board to award compensation. But because medical science has not progressed to a stage where one learned therein can say positively 'this is the cause' or 'that is not the cause,' one who has indubitably sustained an industrial accident, followed by a disease which totally incapacitates him and which it is known may follow such an accident, is not to be denied compensation. The law does not require the impossible. Moral certainty only is required, or that degree of proof which produces conviction in the unprejudiced mind. If the fact that the claimant would not be in his present condition if he had not been injured is fairly deducible from the uncontroverted testimony, then the evidence preponderated against the finding of the industrial accident board and warranted the district court in declaring that its findings against the claimant were unreasonable.

The Supreme Court found the evidence sufficient to support the judgment in Moffett's favor but remanded the case to the district court for proper action with respect to certain stated modifications of the award previously made—*Moffett v Bozeman Canning Co (Mont)*, 26 P (2d) 973

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Treatment of Hypophyseal Infantilism—Shelton and his associates treated six children for a secretory deficiency of the anterior hypophysis. The diagnosis was presumptive in five cases and was verified in one. Four patients were treated by the intraglandular injection of a growth-stimulating fraction of the bovine anterior hypophysis. One was treated with desiccated thyroid and desiccated whole pituitary gland given orally, one was left untreated for twenty-three months and then given the growth-stimulating fraction of the bovine anterior hypophysis. The two latter patients served as controls. The growth increment of the four treated patients was considerably in excess of the expectancy, as computed from the average growth rate for the previous four years, and was slightly in excess of the theoretical normal rate for their ages. It was not definitely determined whether the rate was in direct ratio to the amount of substance administered or whether the potency of the filtered material was altered by the addition of a preservative. The authors believe that the growth increment was greater in the first few months of treatment than subsequently. This may have been due either to a difference in the physio-

logic response or to the difference in the material. One child changed in configuration and appearance. The growth increment for the two control cases was slightly in excess of the expectancy, but below the theoretical normal. The growth increment for the control case, in which the growth-stimulating fraction was given later, was in excess of the theoretical normal and several times the previous rate. The authors do not consider that stimulation of growth has been proved except in one case. Careful observation for at least a year is necessary to verify the results in the other children.

Tuberculin Ointment Patch Test—In the tuberculin ointment patch test, Wolff applies the ointment in the paravertebral region between the eighth and eleventh thoracic vertebrae or on the medial brachial surface. The skin is cleansed with green soap and water, dried, bathed with benzene and dried again. A pea-sized drop of the tuberculin ointment is applied on the right side and a similar sized drop of the control ointment is applied on the left side. Each of these drops is covered with a 2 inch (5 cm.) square of adhesive tape. The test is read in forty-eight hours. The adhesive tape is removed after soaking with benzene and the area is cleansed with benzene. The reaction may be clearly observed ten minutes after the tape is removed. Positive reactions exhibit papules, erythema, induration and pigmentation. A weak positive test shows a few (not more than twenty) discrete pale rose papules of a diameter of from 1 to 3 mm. A medium reaction shows many vividly red papules. A strong reaction shows, in addition, yellow-brown pigmentation of the test area plateaus of induration and marked reddening. The papules may show formation of vesicles. In weak reactions it is advisable to palpate the area in order to detect the follicles and to make a comparison with the control. The author obtained an agreement in 95.8 per cent of the cases between the ointment patch tests and the intracutaneous tuberculin tests (all dilutions) performed on 190 children. The ointment patch test is generally comparable in results with an intracutaneous injection of 0.1 cc of old tuberculin, 1:100.

Smallpox Vaccination of the New-Born—On the basis of 808 vaccinations of new-born infants, Isaac concludes that there is practically no danger associated with the inoculation of mature infants immediately after birth. Reactions are apt to be more severe in premature infants, and it is advisable to postpone vaccination until they show a satisfactory gain in weight. The percentage of takes depends largely on the freshness of the vaccine, but girls seem more susceptible than boys, and more positive reactions are obtained on the thighs than on the arms. Positive reactions do not adversely affect the weight curve and rarely cause elevations of temperature. Moreover, they are not affected by, nor do they affect, the incidence or course of the common intercurrent infections—conjunctivitis, thrush and impetigo. Children of mothers giving positive blood Wassermann reactions rarely show takes.

Hyperactivation of the Neurohypophysis in Hypertensive States—Cushing observed a heavy infiltration of basophilic elements in the posterior lobe in six of nine pituitary bodies from fatal cases of eclampsia and in a number of glands from cases of essential or nephrovascular hypertension. In advancing years there is a tendency for the basophilic cells to wander in large numbers into the posterior lobe. The condition has been looked on merely as a concomitant of old age, particularly when attended by atherosclerosis and renal disease. In essential hypertension, as in eclampsia, lesions affecting the terminal arterioles of the kidneys have been thought to indicate a primary nephrovascular disorder. Necroses in eclampsia, however, are not limited to the liver, nor are the terminal arteriolar lesions in essential hypertension confined to the kidneys. In neither instance do the histopathologic observations account satisfactorily for the clinical symptoms. From his observations the author concludes that the source of these

hypertensive disorders lies in the posterior lobe of the pituitary body, that the extent of basophilic invasion from the pars intermedia is a measure of posterior lobe activity and that excessive infiltration by these elements represents the histopathologic basis of eclampsia and essential hypertension in young persons and may possibly also be related etiologically to the atherosclerosis of old age.

Renal Lesions of Rheumatic Fever—Blaisdell studied the kidney lesions in sixteen cases of rheumatic fever. A perivascular inflammatory reaction of the acute nonsuppurative type, affecting the smaller arteries and arterioles, was present in eight cases. Evidence of perivascular scarring was noted in four, while a recurrent type of inflammation was encountered in two. The inflammatory reaction is usually seen in the adventitial and periadventitial tissues, with occasional infiltration and destructive changes in the medial coat. Intimal changes, consisting of an endothelial swelling and proliferation are inconstant. Glomerular damage which was well marked in only one case, is to be regarded as dependent chiefly on nutritional disturbances brought about by vascular changes. Little evidence of active or healed inflammatory processes was noticed in the glomeruli. No evidence of the specific vascular lesions described by Pappenheimer and Von Glahn was observed in the cases studied. The lesions described, which in general bear a close resemblance to perivascular foci of inflammation found in the myocardium, may be looked on as constituting a definite type of interstitial nephritis. It is seldom, however, that sufficient alteration in structure to justify a diagnosis of renal disease during life occurs.

Total Protein of Cerebrospinal Fluid in Neurosyphilis
—Schube presents a study of the total protein of the cerebrospinal fluid measured to 1 mg per hundred cubic centimeters of cerebrospinal fluid from 446 patients with uncomplicated and untreated neurosyphilis. There were 357 cases of dementia paralytica, forty eight cases of tabes without psychosis and forty four cases of cerebrospinal syphilis with psychosis. The average value for the total protein of the cerebrospinal fluid was 75.4 for all cases of neurosyphilis, 79 in dementia paralytica 57.9 in tabes without psychosis and 65.68 in cerebrospinal syphilis with psychosis. The middle 50 per cent of the cases had a total protein falling between 41.01 and 109.79 mg for all cases of neurosyphilis, between 43.7 and 114.3 mg in dementia paralytica 37.06 and 78.74 in tabes without psychosis and 31.96 and 99.4 mg in cerebrospinal syphilis with psychosis. There is no true difference between any of the means excepting neurosyphilis and tabes without psychosis, and dementia paralytica and tabes without psychosis. In these two instances the difference is so pronounced that there is no question concerning its existence. If 39.99 mg per hundred cubic centimeters of cerebrospinal fluid is accepted as the upper limit of normal protein, it was found that 23.09 per cent of all the cases of neurosyphilis possessed normal values and that 20.72 per cent of the dementia paralytica cases, 29.16 per cent of the cases of tabes without psychosis and 34.09 per cent of the cases of cerebrospinal syphilis with psychosis possessed normal values.

Nonfever Treatment of Dementia Paralytica—Hoverson used a preparation of cerebral lipoid prepared by the Wilson Laboratories first on six patients who were deemed unfit for fever therapy. He gave 1 cc of the preparation intraglutally every other day until an arbitrary number of

twenty injections per person was given. No other form of antisyphilitic therapy was used. Marked mental improvement was noted in five of the patients. In order to improve the laboratory observations, tryparsamide was administered in the usual 3 Gm dose for a period of ten weeks. This was given concurrently, before or after the lipid medication. No marked degree of clinical improvement was observed following as small a number as ten injections. The author observed that lipid and tryparsamide medication together will exert a greater effect in producing improvement from the laboratory point of view than either one will give alone. A gain in weight and mental improvement were noted as before with the first six patients, but in addition more striking serologic results were obtained. He has given the foregoing treatment to twenty-five patients. He found that the injection of a preparation of cerebral lipids in conjunction with the administration of tryparsamide has given a remission rate of 48 per cent in twenty-five cases of dementia paralytica. The treatment is ambulatory and no ill effects have been experienced. This method offers a form of therapy that is applicable to all stages of central nervous system syphilis.

Immunity to Tuberculosis—Sewall and his associates inoculated two groups of guinea pigs with virulent tubercle bacilli in quantities of 0.1 and 0.01 mg, respectively. Half the animals of each group were retained as controls. In the first experiment the dose of infecting bacilli was 0.1 mg. Six guinea-pigs were superinfected with the same dose after fifty-three days, and six after seventy-four days. Twelve controls received only the infecting dose. In the second experiment the infecting dose was 0.01 mg of bacilli. A superinfecting dose of 0.1 mg was administered to six guinea-pigs after fifty-three days, to six after seventy-four days and to six after ninety-five days. The results seem to furnish positive experimental evidence that superinfection has the power, under certain conditions, to increase fibrosis, and in the segregation of foci of infection and actively stimulate resistance to the implantation of fresh foci of disease, if not, indeed, to cause the absorption of established foci. The results of the experiments indicate that the interval of time elapsing between infection and superinfection is a factor of paramount importance in the production of immunity.

Calcified Abdominal Lymph Nodes—Gibson investigated 200 children with diagnoses of various forms of tuberculosis. Abdominal roentgenograms revealed calcified abdominal lymph nodes in nineteen of these patients. He is convinced that the routine use of abdominal roentgenograms in children is important not only as a diagnostic aid but also for the knowledge of tuberculogenesis that may be furnished by this procedure. A single plate may not give the desired information. Serial roentgenograms of the abdomens of children suspected of having tuberculosis should be taken over a period of years. A positive diagnosis of tuberculosis of the abdominal lymph nodes cannot be made until calcification occurs and the disease becomes demonstrable by roentgenogram.

An Infrahyoid Muscular Anomaly—During the dissection of a male subject, aged 53 years, Jackson found an anomalous muscle 110 mm in length, extending in the midline of the neck from the posterior aspect of the manubrium sterni to the middle of the anterior aspect of the body of the hyoid bone. It is asserted that it occurred as the result of a faulty cleavage of the undifferentiated pre-muscle mass in early embryonic life. In support of this statement reference is made to the comparative anatomy, comparative embryology and human embryology of the subhyoid region. An examination of the literature fails to reveal any reference to this muscle. The author suggests that it be termed *Musculus sternohyoideus azygos*, indicating at once its attachments and its unpaired character.

Felt's Syndrome—Price and Schoenfeld report a case in which the arthritic manifestations of Felt's syndrome, characterized by clinical chronicity and relative benignity of the objective features were present. There was swelling of the involved joints with a moderate amount of interosseous atrophy and limitation of motion without roentgenologic evidence of bone absorption or destruction. The microscopic appearance of the knee joint was not distinctive. The active inflammatory process involving the periarticular tissues and synovial mem-

brane was typical of a chronic infection. The authors conclude that the pathologic process responsible for this symptom complex (arthritis, splenomegaly and leukopenia) is not new or distinctive but probably results from a chronic infection.

Analgesic Effect of Hepatitis and Jaundice—During the past four years Hensch made observations on the effect of intermittent intrahepatic jaundice on the chronic pain experienced by sixteen patients with chronic arthritis, fibrositis and sciatica. In two of the cases the intrahepatic jaundice apparently was not related to drugs, in fourteen it was considered to be toxic hepatitis caused by cinchophen. Coincident with the onset of jaundice, fourteen of the patients received partial or complete relief of pain for variable periods. In five of the six cases in which the joints were swollen reduction of the swelling, sometimes complete, was noted. Five of the sixteen patients experienced complete relief of pain for from two weeks to eight months, and in one instance for seven years after the disappearance of the jaundice. Four patients noted complete disappearance of pain with the onset of fatal hepatitis and jaundice caused by cinchophen, the analgesia persisted until death. In one case, complete relief of pain was noted only for the duration of icterus, in another case pain disappeared completely at first, returning slightly during the latter part of the period of jaundice. Two patients had marked, although not complete, relief of pain during the period of jaundice, and for two weeks and five months, respectively after the jaundice subsided. No amelioration of pain was experienced by two patients with slight jaundice. One patient noted some relief, which later was lost, even in the presence of definite icterus. In an additional case of chronic infectious arthritis and hepatitis caused by cinchophen, without jaundice, the patient did not become jaundiced and the pain was not relieved.

Acute *Streptococcus Viridans* Endocarditis—Held and Goldbloom observed that *Streptococcus viridans* was the cause of four cases of acute, rapidly fatal endocarditis occurring on the basis of a previously diseased valve. This form of endocarditis is usually preceded by an acute infection. The primary infection precedes the acute endocarditis by only a few days and it may efface the symptoms of endocarditis, making the diagnosis of acute endocarditis caused by *Streptococcus viridans* impossible before death, as in the case in which the condition was preceded by pneumonia. In the authors' cases the symptoms of septicemia were in the foreground. They believe that the reason the cases reported had a rapidly instead of a protracted fatal course is that there was almost a total loss of the reactive power of the reticulo-endothelium of the endocardium. A primary factor in the nonreactive quality of the reticulo-endothelium was the immediately preceding acute infection. Because the reticulo-endothelium of the endocardium was nonreactive, local inflammatory changes were minor and destructive changes were maximal.

Thoracic Stomach. Report of Five Cases—Goodall and Hoyt believe the condition of thoracic stomach to be fairly common. Its seeming rarity is due to the fact that cases,

especially of the type in which the greater part of the stomach is below the diaphragm have been overlooked by the roentgenologist and probably by the pathologist. The clinical symptoms are characteristic enough to permit a tentative diagnosis. Dyspnea due to slight exertion and occurring in the latter part of life as well as unmitigated gastro-intestinal symptoms with negative routine roentgen observations, are suggestive of thoracic stomach. The final diagnosis is made by the roentgenologist and this necessitates a routine determination of the length of the esophagus in all gastro-enteric examinations. The occurrence of ulcer in the thoracic stomach cannot always be demonstrated by roentgenograms.

- Diverticula of the Thoracic Portion of the Esophagus. Report of Forty Two Cases. P. P. Vinson. Rochester, Minn. —p. 508.

Fatal Complications of Otitis Media—Courville and Nielsen reviewed the protocols of 10,000 necropsies with special attention to the intracranial complications of otitis media and mastoiditis. The highest death rate occurs in the first year of life, when intracranial complications are inclined to be less common. In some cases otitis media is an incidental finding and plays no part in the fatal issue of the case (terminal otitis). In infections of the petrous pyramid, extradural abscess and meningitis are the most common. Thrombosis of the cavernous sinus and abscess of the temporal lobe are extremely rare, and unequivocal cases have not yet been described in the literature. The authors discuss dural infections, subdural abscess, dural fistula, the incidence, pathogenesis and consequent complications of thrombosis of the venous channels, the distribution of metastatic foci secondary to thrombosis of the lateral sinus, the chronic forms of arthritis and their role in the formation of arachnoid cysts, primary and secondary types of meningitis, otitis as a cause of encephalic abscess and retrograde extension of infection by way of the venous channels as a cause of abscesses of the parietal and frontal lobes.

Periarteritis Nodosa of the Temporal Bone—Druss and Maybaum describe the clinical features and histologic alteration in the temporal bone in a case of periarteritis nodosa. The smaller arterioles in the bone marrow of the petrous pyramid showed changes characteristic of periarteritis nodosa in the acute stages. Some showed subintimal proliferation with narrowing of the lumens, fibrinoid necrosis of the media and adventitia and perivascular cellular infiltration, mainly of the polymorphonuclear variety. In one of the vessels in the region

of the subarcuate fossa there was a definite aneurysmal dilatation as a result of a hyaline degeneration and necrosis of the media, intimal proliferation and perivascular infiltration were also noted. Certain of the periosteal vessels, particularly about the nerves and ganglions, showed the alterations usually found in arteriosclerosis, such as thickening of the intima and reduplication of the internal elastica. Three patches of otosclerosis were noted in the labyrinthine capsule, one in the region of the oval window, the site of predilection, another in the modiolus and a third in the promontory at the outer insertion of the secondary tympanic membrane. A careful study of the blood vessels in these otosclerotic areas was made, but the characteristic changes found in periarteritis nodosa were not seen. Except for the changes that have been noted, the middle ear and labyrinth were essentially normal.

Abscesses of the Liver Caused by Bacteroides Funduliformis—Beaver and his associates present two cases of hepatic abscess caused by Bacteroides funduliformis. The genus Bacteroides (Bergey) comprises certain anaerobic nonsporulating bacilli. It is probable that infections of this type are not rare and that the large intestine and the genito-urinary tract of the male seem particularly vulnerable to primary infection. In the colon infection appears to originate principally in infected carcinomas, although the focus may be cryptic. From the primary focus, direct hematogenous dissemination may occur to the liver or the lungs, with clinically demonstrable bacteremia frequently supervening. Such infections are extremely serious and offer a grave prognosis. Their clinical syndrome is typical of an extreme degree of toxicity, with a high, remittent type of fever, chills, perspiration and weakness progressing to exhaustion. The physical signs vary with the localizations of the infection. The lesions of the liver, as the authors have observed them, have been essentially chronic granulomatous abscesses, frequently multilocular and spreading with destructive changes, necrosis of tissue and exudation. In the lungs, the lesions have appeared as small septic infarcts, patches of bronchopneumonia or small abscesses. Firm, solid, grayish or hemorrhagic nodules were found most often. The gravest areas resembled beginning caseation necrosis. Other investigators have described large putrid or gangrenous abscesses of the lungs with empyema associated with organisms of this group. Such lesions are apparently primarily pulmonary, usually the result of an aspirated infection. Guinea-pigs and rabbits are susceptible to experimental inoculation with Bacteroides funduliformis. The lesions produced were abscesses, similar in appearance to those occurring in man.

Isolation of Ether from Human Tissues—Gettler and Siegel outline a micromethod for isolating ethyl ether from human tissues. The organs removed at necropsy are placed quickly in glass jars, sealed tightly and put in a refrigerator. When the material is ice cold, about 600 Gm is ground up quickly, and 500 Gm of the ground mass is mixed with 200 cc of ice cold water and placed in a 2 liter flask. An additional 300 cc of water and 1 cc of liquid petrolatum are added. The mixture is distilled with steam until 200 cc of distillate is collected. A long well cooled condenser, the tip of which has been bent to resemble an adapter, is used. The bent tip should dip into 25 cc of ice water contained in the receiving flask, the latter being at all times entirely surrounded by ice. The entire 200 cc of distillate is poured through the safety tube into a modified rectification flask and 1 Gm of granulated zinc is added. The receiving tube is surrounded by a bath of solid carbon dioxide in acetone and should contain 0.15 cc of water.

so that the ether is collected over water as a separate layer. The rectification flask is heated, an asbestos centered wire gauze and a microburner being used. As soon as the solution begins to boil, the flame is regulated so that the liquid boils gently in the bulb for about fifteen minutes. During this time the steam must not be permitted to rise beyond half the height of the liquid. Then the flame is increased gradually so that the steam is made to rise in one minute until it passes the bend. The ether, if present, will be found unfrozen in the calibrated receiver. When the rectification is completed, the receiving tube is removed from the acetone bath, lightly stoppered and allowed to stand at room temperature until any ice in the calibrated receiving tube melts. The volume of recovered ether (upper layer) is read immediately. The authors isolated and measured ether in amounts as small as 0.06 cc in 500 Gm of tissue. In tissues containing from 0.3 to 0.9 cc of ether in 500 Gm, the recovery is 83.6 per cent (average). The recovery of ether is fairly constant and can be used for estimating the amount originally present in the tissues. Determinations of the microboiling point served to identify the isolated liquid as ethyl ether.

Anatomic Basis for Splanchnoptosis—According to Viator the most easily displaceable viscera are the kidneys, the stomach, the redundant portions of the colon, the liver, the lungs and the heart. When the kidneys and suprarenals are projected forward, they enter the lumbo-iliac inclined planes which furnish direct paths for descent. As the kidneys descend, they separate from the suprarenals. The intervisceral attachments elongate and make traction on the suprarenals. The latter elongate but remain fixed. Traction is also made on all the structures of the hili. The distending stomach normally finds a descending oblique plane which guides it downward, forward and to the right. The fundus remains under the left vault of the diaphragm. The movable part of the first portion of the duodenum shares in the movements of the antrum, and it may undergo traction, pressure, kinking, torsion or obstruction. The spleen tends to descend with the stomach and elongate its lowest portion becoming tongue shaped and extending downward and forward on the splenic flexure. The transverse colon is always more or less redundant, forming one or more loops. When the loops are unfolded, they tend to descend to exert traction on their attachments and to cause kinking and stasis at their angles. The liver remains under the right vault of the diaphragm. It is subject to forward backward and lateral rotations, however within the limits of its attachments. When the traction exceeds the limitations, the tissues of the attachments yield and the liver becomes wholly or partially elongated or otherwise modified in shape. The lungs always remain attached at their hili but descend by elongation or by other changes in shape, as the thorax shares in the changes in body form and in the altered action of the diaphragm due to ptosis. The heart, owing to the pericardium and the other firm mediastinal tissues, remains attached to the structures at

the base. However, it tends to rotate downward and from left to right toward the median line, the apex leading. The portion of the heart to the right of the median line also moves medially.

Experimental Bone Transplantation and Effect of Decalcification—Ghormley and Stuck studied the rate and the type of healing of grafts taken from bone of different regions and structures and the effect on the rate and the type of healing that could be produced by "decalcification" of experimental animals. Their experiments revealed that periosteal transplants in old animals do not produce new bone. Cortical transplants do not completely die but unite slowly with the bone of the host and decreased calcification is seen roentgenologically at the end of three months. Cancellous bone from the humerus or the tibia unites more rapidly and firmly than cortical bone. It gives roentgenographic evidence of increased calcification at the end of three months. Animals placed on a decalcifying diet until the time of the transplantation gave evidence of greater active production of new bone round both the cortical and the cancellous transplants.

Localization of Tumors of the Spinal Cord—Elsberg and Dyke examined the roentgenograms of 100 normal spines and the roentgenograms of eighty-six patients in whom the diagnosis of intradural or extradural tumors of the spinal cord had been verified. In addition the roentgenograms of a number of patients with intramedullary growths, syringomyelia and other intramedullary diseases which had produced a localized enlargement of the spinal cord and a series of patients in whom at operation, adhesions of the arachnoid were found as the only grossly visible lesion were studied. Measurements were made of the size of the vertebral canal in fractures of the vertebrae. The study showed that in tumors of the spinal cord there is often an increase in the size of the vertebral canal at the level of the growth, which can be recognized only by measurements of the space between the pedicles. This enlargement of the canal was found in 42 per cent of sixteen cases and was especially frequent in tumors between the tenth thoracic and the sixth lumbar vertebra. The cases of extradural tumor showed the increase in the size of the canal in 18 per cent of growths in the cervical and upper thoracic regions in 12 per cent of growths between the fourth and the ninth thoracic vertebra and in 60 per cent of growths below the level of the ninth thoracic vertebra. The enlargement of the vertebral canal occurred in fourteen of nineteen cases of extradural tumor. In nine of these, other changes were recognized in the bone which made diagnosis possible. In five the nature and location of the lesion could be demonstrated only

by the measurements of the interpedicular spaces of the vertebrae. In the midthoracic region, a pathologic increase in the size of the vertebral canal was much more frequent in the cases in which the expanding lesion was extradural. At the level of the tumor the inner borders of the vertebral pedicles were often flat and sometimes concave. This was of diagnostic significance only when associated with a measurable increase above the normal in the size of the interpedicular space.

Symptoms and Diagnosis of Extradural Cysts—According to Elsberg and his associates the characteristic syndrome of compression of the spinal cord by an extradural cyst consists of the following. The individual is an adolescent presenting the history and symptoms of a progressive spastic paraplegia. Pain is absent or is not a prominent symptom. The objective disturbances of sensibility are slight and their upper level is in the midthoracic region, usually at the sixth or seventh thoracic dermatome. The manometric tests demonstrate a subarachnoid block with the characteristic spinal fluid changes of cord compression. Measurements on anteroposterior roentgenograms show that the interpedicular spaces of three or more vertebrae somewhere between the fourth and the tenth thoracic vertebra are enlarged. The pedicles of the affected vertebrae, especially those of the sixth, seventh and eighth, are narrowed and atrophic. This combination of symptoms and signs with the characteristic changes in the bony part of the spine justify the diagnosis of large extradural cyst.

Amyl Nitrite Test for the Differentiation of Tumors—Hare used the amyl nitrite test in eighteen cases of tumor of the brain, in twenty-two cases of vascular lesions, in eighteen cases of chronic inflammatory disease and in approximately fifty persons who showed no evidence of organic disease of the brain. In sixteen of the cases of tumor of the brain the rise of the fluid in the manometer varied between 330 and 520 mm. In several cases the spinal fluid was forced out of the top of the manometer tube. In two cases the level of the fluid rose to 260 and 270 mm. Necropsy several months later revealed cerebral tumors with extensive cerebral softening in both cases. In nineteen cases of cerebral arteriosclerosis or marked vascular lesions, the inhalation of amyl nitrite by the patient caused a rise of spinal pressure to between 130 and 315 mm. In three patients, two of whom were suffering from a high degree of hypertension the rise was to 455, 400 and 360 mm, respectively. In sixteen of the patients presenting inflammatory lesions, mostly cases of chronic encephalitis or syphilis, the rise varied between 85 and 320 mm. In two cases of arterial hypertension superimposed on the inflammatory disease the fluid mounted to a level of 360 and 400 mm, respectively. The pressure readings for the majority of the control group were about equally distributed slightly above and below the 320 mm level. From these results the author concludes that the amyl nitrite test is of value as a diagnostic aid in differentiating between expanding lesions and inflammatory or vascular diseases of the brain and that it is not of value as a method of differential diagnosis between pathologic and normal conditions in the brain.

Chronic Sinus Infection—Kratav employed topical and general administrations of antigenous endo antigens prepared according to the method of Krueger, in the treatment of chronic and subacute sinus infections. This procedure apparently results in an increased ability of the host's tissues to handle the infecting agent. The tissue response is largely phagocytic in nature. It is not possible to employ a fixed scale of dosage. Individual

variations in tolerance are considerable, although the author did not observe untoward reactions in his series of forty-five cases. His analysis of the end results in the forty-five cases treated by this method shows satisfactory improvement in 95 per cent and marked improvement or cure in 66 per cent. He has started treatment with the weaker solution, administering the antigen hypodermically three times a week, the first dose being 0.1 cc intradermally and 0.1 cc subcutaneously. It has been found more satisfactory to make these injections in two separate areas, 2 or 3 inches apart. The intradermal dose remains the same throughout the treatment, while the subcutaneous dose is raised as rapidly as possible to the maximum, usually from 0.5 to 0.8 cc, four or five maximal doses of the weaker solution being given. Care should be exercised always to remain just below the reaction dosage. Reactions are rarely encountered and are never severe but the author feels that treatment is more satisfactory when they are avoided. The stronger solution is used now and the same procedure is followed. The entire course requires from ten to fourteen weeks for completion.

Relation of Allergy to Immunity in Tuberculosis —
Rothschild and his associates obtained complete desensitization to tubercle bacilli and to tuberculin in tuberculous guinea pigs by a prolonged and properly graded course of subcutaneous injections of Koch's old tuberculum. The desensitizing power of purified tuberculoprotein is less in proportion to its power to produce allergic reactions than is that of Koch's old tuberculum. Long continued daily subcutaneous injections of massive doses of concentrated glycerin broth in some instances desensitize tuberculous guinea-pigs to tuberculin. This nonspecific desensitization is not due to the glycerin contained in the broth. It is not known whether this nonspecific desensitization is free from the danger of perifocal reaction. Infection in desensitized immune animals does not introduce into the histologic picture of tuberculous lesions features that are novel to the pathologic condition of human tuberculosis. In these respects the reaction of the desensitized animals was equal or superior to that of the nondesensitized controls. So far as the inhibition of spread of lesions from the site of infection to the viscera may be used as evidence of local fixation of bacilli the desensitized, nonallergic immunes were able to resist the spread of infection as successfully as the allergic immunes.

Filtering Capacity of Lymph Nodes—Drinker and his associates, using a series of anesthetized dogs, perfused the popliteal lymph node alone and the popliteal and iliac lymph nodes with solutions containing dog erythrocytes and streptococci. The perfusions have been carried out under conditions of lymph flow and pressure within the limits of those occurring in the actively moving dog, or after a severe degree of inflammatory swelling has developed. The study indicates that normal lymph nodes possess a high degree of filtering efficiency—an efficiency so great as to make it fairly certain that in a part kept at rest early in an infection practically no microorganisms would escape the nodes in the line of drainage.

Studies on Typhus Fever—The experiments of Zinsser and Ruiz Castaneda demonstrate that under suitable experimental conditions guinea-pigs can be protected from infection with the European type of virus by the serum of a horse immunized with killed rickettsiae of the Mexican type. These results seem to them to bear on the differences of opinion that exist concerning the closeness of the relation between the two types of virus. It is their opinion that the differences are much less fundamental than they have been supposed to be and that it is not impossible that they depend largely on minor modifications (adaptations, possibly reversible) sustained in the course of the passage of the Mexican, so-called New World virus through rats and rat fleas. The results of these experiments show beyond question that the serum of a horse treated entirely with Mexican rickettsiae acquires a Weil-Felix reaction, agglutinates the European louse vaccines of Weil and protects against the European virus. The results support the view that closely relates these two infectious agents. These results are of importance with regard to the development of a protective serum for prophylactic and therapeutic application to the European disease, because in the

past, it has not been possible to obtain, with the European virus anything like the large accumulations of rickettsiae that the authors have been able to produce with the Mexican strain by their roentgen method.

Influence of Roughage on Protein Digestibility—Adolph and Wu fed rats different amounts of filter paper, china clay and rice chaff with a cooked rice diet. The results indicate that neither varying the total amount of food nor adding large amounts of these bulk materials produces any significant effect on the degree of digestibility of the food protein. China clay was fed in amounts up to 80 per cent of the total intake. It would appear that great bulk in the alimentary canal does not interfere with the action of proteolytic enzymes. Agar-agar caused a rapid passage of the food material through the alimentary tract and showed distinctly lowered values for protein digestibility. An experiment with two human subjects in which cabbage fiber was fed with a meat-rice diet showed a slight tendency toward a lowered degree of protein digestibility only when the fiber was ingested in an abnormally large amount. The authors believe that lowered values for nitrogen digestibility on a given diet result only when the food material passes through the alimentary tract with unusual rapidity.

Visceral and Somatic Activity Following Use of Hypnotics—Quigley and his associates studied the effect of a range of doses of pentobarbital, amytal and barbital administered intravenously on the tone and motility of the stomach, ileum and colon by the balloon method in trained, unanesthetized dogs. The action of barbital has been checked by direct observations using the paraffin bath method. The visceral response has been correlated with the hypnotic action of these compounds. Motor activity of the intestine was depressed in a qualitatively similar manner by each of the barbitals. Maximal depression frequently developed most rapidly in the colon and last in the stomach, complete recovery usually occurred early in the ileum and late in the stomach. With doses of the barbiturates producing equal degrees of hypnosis gastro-intestinal depression was longest with barbital, intermediate with amytal and shortest

with pentobarbital. Excitation from barbitol and pentobarbital was more frequent with small than with moderate dosages. The maximal dose of amytal produced marked restlessness. The frequency with which excitement or restlessness was observed was greatest with amytal and least with pentobarbital. Dosages of tribrom-ethanol having a slight hypnotic action markedly depressed the gastro-intestinal tract (order of depression, stomach, ileum, colon), but the visceral effects persisted only from 0.6 to 0.8 time as long as the period of hypnosis. The somatic depression produced by tribrom-ethanol fluid exceeded that from tribrom-ethanol crystals, in that the maximal effects of the fluid developed somewhat earlier, were of greater degree and persisted from one and one-half to two times as long as with the crystals. This indicated that the rate of absorption of an aqueous solution of tribrom-ethanol fluid from the dog's colon equaled or exceeded that of a similar solution of the crystals. The amylene hydrate contained in the fluid may have produced a moderate irritation of the colon.

Thrombosis of the Renal Veins.—Hepler reports two cases of thrombosis of the renal veins. One represents a postscarlatinal thrombosis of the vena cava that evidently existed for some time with the establishment of a collateral circulation. Visceral involvement was late and started as a hemorrhagic infarction of the left kidney from a secondary thrombus in the left renal vein. Recovery after removal of the left kidney was prevented by a secondary thrombosis of the right renal vein ten days later. However, the marked improvement following nephrectomy indicates the feasibility of surgical intervention even in the presence of extensive extrarenal thromboses if the condition is unilateral, as it is in half of the reported cases, and the infarction is not overshadowed by the primary or associated disease. The fact that this lesion presents a definite syndrome consisting of sudden onset of hematuria, lumbar pain and tenderness and rapid, progressive enlargement of the kidney, should ensure its more frequent clinical recognition. With this presumptive evidence the additional cystoscopic observations of unilateral bleeding, reduced or absent function and an enlarged outline of the kidney with no shadows on excretory urography, are diagnostic. The condition is not uncommon in infants, in whom it is usually primary and associated with severe enteritis overshadowing the infarction, as it did in the author's other case, and precluding the possibility of surgical intervention. In these cases at the time of total infarction of one kidney there is frequently a beginning capillary thrombosis on the opposite side. In older children and adults the thrombosis is usually secondary and unilateral. Although practically all thrombi arise on the basis of infection, suppurative thrombophlebitis is rare in infants. It usually occurs between the ages of 25 and 50 years and is secondary to severe suppurative lesions of the kidney, either hematogenous or ascending. In the surgical treatment of pyogenic infections of the kidney, the possibility of an infected thrombus in the renal vein as a continued source of blood stream infection must be considered.

Snapping Thumb in Childhood.—In contradistinction to the usual statements regarding age, sex and cause of the snapping thumb in childhood, Hudson offers eight cases (two bilateral) seen within two years all occurring at the age of 3 or earlier, with no distinctive sex incidence. The same etiologic factor, localized tendon enlargement leading to disproporition between the tendon and its sheath, was present and the flexor pollicis longus was affected in each case. In only one instance was there a definite history of trauma and in no instance had the fingers or hand been used in an abnormal fashion. In one case a familial incidence was recorded. Six of the eight cases, including both the bilateral instances, were proved by operation.

Insulin in Diabetes Mellitus.—Holcomb determined the insulin requirements of forty-three diabetic patients on various diets. His observations reveal rather definite evidence that

the insulin requirement is dependent not alone on the grams of carbohydrate in the diet but also on the fat and all other elements entering into the metabolism. There is no constant scale of insulin dosage for a given quantity of carbohydrate in the diet. The ratio between grams of dextrose and units of insulin varies widely, not only in different patients but also in the same patient under various conditions of health and activity. The total calories of the diet more nearly determine the insulin dose than does the total dextrose, and the so-called dextrose equivalent of insulin varies too widely to be recognized as a useful constant factor in determining insulin dosage in diabetes.

Sarcoma of the Duodenum Treated by Partial Duodenectomy—Williamson cites a case of primary sarcoma of the duodenum in which the tumor started as a fibroma of the duodenum and underwent malignant degeneration. The diagnosis of a duodenal tumor was made during the course of an exploratory laparotomy. A preliminary posterior gastro-enterostomy was performed six months later in anticipation of extirpating the tumor. A partial duodenectomy was successfully performed about eleven months after the diagnosis and the patient had an uneventful recovery. The duodenum is infrequently involved by malignant conditions, making its partial or complete resection necessary or desirable. The author believes that when such a condition exists, other factors being equal, operation should be undertaken with a reasonable hope of success, although, as in his case, it may be necessary or desirable to precede the actual attack on the duodenum by a preliminary gastro-enterostomy. The reimplantation of the common bile duct and the major pancreatic duct into the intestine either together or separately can be done with a high degree of success and has been done experimentally by Mann and his co-workers. It seems that the surgeon is justified in attempting a curative type of operation for a resectable tumor of the duodenum even though it may necessitate the reimplantation of the common bile duct, the ligation of the duct of Santorini and the reimplantation of the duct of Wirsung.

*Postoperative Pulmonary Complications H F Griffiths —p 89
Normal Regulation of Respiration S Wright —p 110

Postoperative Pulmonary Complications — Griffiths recommends that 1 The preoperative and postoperative use of sedatives should be limited, as all sedatives tend to depress the respiratory center. 2 Larger doses of atropine than are usually employed should be prescribed to diminish excessive secretion of the bronchial mucus. The suggested dose is $\frac{1}{50}$ gram (0.0013 Gm) for adults and proportionately less for children according to the age. 3 No binder should be applied to the patient's abdomen, dressings should consist only of a roll of gauze secured by deep sutures. 4 All patients should be made to exert strong expiratory movements at frequent intervals for at least the first forty-eight hours after operation. The use of mixtures of carbon dioxide and oxygen appear to be contraindicated, because they cause strong inspiratory movements, which may result in the mucus entering deeper into the lung. Also patients, when conscious, are rendered extremely uncomfortable by the administration of these mixtures. The complications that are most frequently encountered are acute bronchitis or bronchopneumonia of varying severity, which may clear spontaneously, or obstruction of bronchioles by tenacious mucus may cause collapse of part of one or both lungs. Treatment should be directed toward the expulsion of the mucus by coughing, rather than to hyperventilation by mixtures of carbon dioxide and oxygen.

Bicolored Guaiac Reaction in Mental Hospital Practice S W Hardwick —p 87

Lipoid Metabolism in Mental Disorders — Sharpe states that the lecithin content of the blood in mental disorders shows no important variation from the normal. The cholesterol content of the blood in early dementia præcox is decreased about 25 per cent. Later there is an increase of about 30 per cent and it remains at that level. This increase may be due to a hyperactivity of the suprarenals. The coefficient of utilization is low. In melancholia and confusional insanity the cholesterol content of the blood is slightly increased above the normal. The coefficient of utilization is low in these groups, denoting deficient oxidation and low metabolic activity. Cases of recurrent mania

show a high blood cholesterol, particularly during an acute attack. The cyclic nature of the condition suggests that it is caused by a derangement in metabolic activity, probably involving the suprarenals, as evidenced by the blood cholesterol increase. The coefficient of utilization is high, indicating increased metabolic rate. There exists in the blood in certain melancholic and confusional states a powerful depressor substance having a choline-like action on the isolated frog heart. This substance is antagonized by epinephrine. Normally the depressor substance is in such small concentration as to be almost undetectable. In dementia præcox and recurrent mania this substance exists in small quantities, approaching the normal figure as determined by the physiologic test. Choline added to active serum disappears on standing after a few hours at laboratory temperature. The choline added to serum inactivated at varying temperatures remains. Some substance having the properties of an enzyme is destroyed by heating. These observations suggest that there is a deficiency or complete absence of such a substance (conveniently termed "cholinase") in melancholia and confusional insanity. Hypotonia is a clinical feature of these cases.

Blood Cholesterol in Epilepsy — McLean attempts to correlate the work of Shaw and Sharpe with the methods of treating epilepsy by dehydration and ketogenesis. Sackett's method was used for the determination of cholesterol. The cases investigated were all of many years' standing. The patients were confined to bed without medication. Blood was collected at intervals of four hours. The observations indicate that the amount of blood cholesterol is lowered at the time of an epileptic attack. The author believes that the increase in concentration of cholesterol and urea in the treatment of epilepsy by dehydration is due entirely to the mechanical effect of the limitation of fluids. He suggests that the mechanical effect of limitation of fluids is assisted by the increased concentration of cholesterol. He placed two patients on a strict ketogenic diet for fourteen days. The results show a rise in the cholesterol level during ketosis. They are not conclusive, however.

Dextrose Tolerance and the Activity of Insulin — Himsworth presents experiments which show that the administration to a rabbit of a diet rich in fat decreases the sugar tolerance, retards and diminishes the action of insulin on the blood sugar, prevents or delays the progressive improvement of sugar tolerance that occurs on injection of consecutive doses of dextrose, and impairs the ability of insulin to diminish the hyperglycemia following intravenous injection of dextrose. The administration of a diet rich in carbohydrate improves the sugar tolerance, accelerates and increases the depression of the blood sugar by insulin, favors the progressive improvement of sugar tolerance after consecutive injections of dextrose, and does not impair the action of insulin in reducing the hyperglycemia after intravenous administration of dextrose. The author concludes that these results can be explained on the basis of the experimental observation that fat diets and starvation diminish the susceptibility of an animal to insulin, while carbohydrate diets and the administration of dextrose increase the susceptibility to insulin. He suggests that the susceptibility of an organism to insulin can be explained by the hypothesis that insulin is prepared and secreted by the pancreas as an inactive substance, that it is activated in the body by an unknown factor, and that

the production of this unknown activator is increased by the administration and diminished by the withdrawal of carbohydrates

Castellani's Test for Albuminuria—Hoffmann gives Castellani's test for albuminuria, which is as follows. The filtered urine, 5 cc, is placed in a test tube and 15 cc of liquefied phenol is added by pouring it slowly down the sides of the tube by means of a pipet. The liquefied phenol will collect at the bottom of the tube. If within two minutes a definite white ring forms where the two liquids come in contact the test is considered positive, namely, the urine contains albumin. The author has found that it is quite as sensitive as other similar methods and that it always shows the reaction in a clear and distinct way. He has never seen false positive reactions in the negative urines that have been examined as controls. He finds the method exceedingly useful for the daily routine work of the practitioner and still more for hospitals and laboratories. It is also an easy control for other tests in doubtful cases.

Acute Pneumococcal Pharyngitis—Henderson presents the case records of eleven patients with acute pneumococcal pharyngitis. There was little variation in the clinical manifestations throughout the group. There was no suggestion of contact with an acute or recent case of lobar pneumonia or bronchopneumonia or another similar pneumococcal tonsillitis. There was, however, a severe epidemic of pneumonia and influenza in the city at the time. All the cases were sporadic except in one there was no associated injury or illness (a fish salesman who had just returned to work after being off duty for a fortnight with so-called influenza). The onset was rapid, attended with fever of from 100 to 103 F and shivering. Local symptoms were remarkably constant, viz severe sore throat, dysphagia and tender cervical glands, which in most of the cases were definitely enlarged. In all there was intense inflammation and edema of the pharynx with membranous involvement of the tonsils, uvula, soft palate and posterior pharyngeal wall. Macroscopically, the exudate was similar in appearance in each case. Those seen early showed a gray slimy glistening adherent exudate. Soon, however, there appeared erosion of the mucous membrane with petechiae and the membranous exudate rapidly became dark and necrotic. Local tissue destruction and sloughing resulted, but there was no characteristic fetor. In three of the patients respiratory embarrassment was sufficient to warrant tracheotomy. In ten cases there was an associated pneumococcal septicemia. Only one patient recovered, all the others had a rapid and fatal termination. A throat swab and blood culture were taken on admission in each case but once, an early case, in which death occurred eight hours after admission and a blood culture was omitted. This patient, however, showed the pneumococcus in the throat in practically pure

culture, and had all the typical signs and symptoms. The pneumococcus was found as the predominating organism in the throats of all patients and all the blood cultures taken showed an associated pneumococcal septicemia. Serologic examination of the various strains of pneumococci showed that one patient was infected with type I, four with type III and six with group IV.

Transplantation of Living Grafts of Thyroid and Parathyroid—Stone and his associates believe that in the transplantation of living grafts of thyroid and parathyroid tissue a proper site should be selected and the form and size of the grafted material, the adaptation of the graft to the chemistry of its host and the existence of a state of deficiency causing a physiologic need of the tissue to be grafted should be considered. They have secured cross grafts of thyroid and parathyroid tissue which when removed, seemed to be entirely healthy and growing vigorously at varying periods from twenty-one to eighty days after the implantation. There have been a great many failures but the proportion of success has been sufficient to show that cross grafting of these endocrine glands is possible when all the conditions of the experiment are favorable. The method has been applied to two cases of human parathyroid tetany and four cases of thyroid deficiency. One of the tetany patients has lived one year since the first graft and the other seven months. They are entirely well clinically, and their blood calcium has returned to normal from a low level of 46 and 62 mg per hundred cubic centimeters, respectively. The thyroid cases are too recent to make any report on. The details of the technique of tissue culture for these grafts of endocrine glands follow, in general, the principles well established for the growth of mammalian tissue. A small fragment is placed, under sterile conditions, on a coagulated medium and kept in a thermostat until it begins to liquefy the surrounding medium by its growth and chemical activity. It is then transplanted to a new culture medium. In actively growing tissues this may have to be done every second to fourth day. The medium consists of Tyrodes solution with extract of beef embryo as a stimulating substance, and serum and plasma derived from the animal in which the graft is to be placed. Enough serum and plasma to form a coagulum of fibrin are always used.

Detection and Estimation of Alpha-Dinitrophenol—Bolliger states that, by the addition of a solution of methylene blue to a solution of dinitrophenol methylene blue, dinitrophenolate is obtained, which crystallizes in fine bronze-colored needles. This compound is sparingly soluble in most solvents forming a green solution. Its solubility in chloroform is greater. The acidified solution is extracted with chloroform, and to the neutralized chloroform extract a dilute solution of methylene blue is added. If dinitrophenol or a similar compound is present the chloroform extract will become green. To examine urine for traces of dinitrophenol, 20 cc of urine in a separating funnel is acidified with one tenth of a volume of a 70 per cent solution of sulphuric acid. It is then extracted by gentle shaking for about three minutes with half its volume of chloroform. Permanent emulsions should be avoided. If, after standing, a sufficient quantity of chloroform does not separate cleanly, the chloroform must be separated by centrifugation. About 10 cc of the chloroform extract is transferred to a test tube containing 1 Gm of calcium carbonate. The contents are mixed well and 0.0001 normal methylene blue, chemically pure (about 0.004 per cent), is added in small drops. The mixture is shaken after every drop till the first change of color occurs. It is then filtered through a dry filter into another test tube and an equal amount of distilled water is added. It is shaken thoroughly and the water is removed. If the chloroform shows a distinct green color which cannot be extracted by further washings with water alpha dinitrophenol is present in the

urine In the detection of dinitrophenol in the blood stream of a nonjaundiced person, serum acidified with a few drops of sulphuric acid is thoroughly shaken with an equal amount of chloroform. Then the mixture is centrifugated and the chloroform extract is pipetted off and filtered through a dry filter into a test tube containing some calcium carbonate. Then 0.0001 normal methylene blue is added in small drops till the mixture begins to change color. After filtering, the presence of dinitrophenol is indicated by a green tint of the chloroform extract. For the quantitative determination by titration of dinitrophenol in proprietary medicines, a known amount is dissolved in a 5 per cent solution of sodium hydroxide. After the solution is acidified with a 70 per cent solution of sulphuric acid, the dinitrophenol is extracted with several lots of chloroform. The combined chloroform extracts are treated with calcium carbonate, filtered and made up to a known amount. An aliquot part of the chloroform extract is transferred to a separating funnel and 0.0001 normal methylene blue is added from a buret. The technic of the titration is the same as the one described for the determination of trinitrophenol with methylene blue. The methylene blue combines with the dinitrophenol to give the chloroform-soluble methylene blue dinitrophenolate. Therefore, on extraction the watery layer originally containing the methylene blue turns yellow, while the chloroform takes on a green color. The end point is reached when the watery layer becomes colorless. The test described is not specific for 2,4-dinitrophenol. A similar compound is given by 2,4,6-trinitrophenol and this can be differentiated from the dinitro compound by the greater solubility in chloroform. In general it seems that all polynitro derivatives of phenol and naphthol with a nitro group in orthoposition to the hydroxyl group form with methylene blue an addition product, which dissolves in chloroform with the formation of a green color.

*Anatomic Changes in the Diaphragm Following Phrenicectomy Report of Eleven Necropsies W S Stanbury—p 300

Phrenic Evulsion in Control of Cavitation—In his fifty cases Russell found phrenic evulsion to be of definite value in controlling cavities in the apex and upper lobe. It should be considered in all such cases, no matter what size or type of cavity may be present. It is of most value in combination with artificial pneumothorax. As a method of dealing with adhesions preventing effective collapse it offers an alternative to cutting which is effective, easily performed and practically without complications. It was relatively of more value in women the figures being 63 per cent in women and 47 per cent

in men. Upper lobe cavitation occurred approximately twice as frequently in the left lung as in the right. Phrenic evulsion was relatively of more value in left-sided lesions (59 per cent) than in right-sided lesions (47 per cent). The operation appeared to affect thick-walled and thin-walled cavities equally. It was of most value in controlling medium sized cavities (62 per cent). The average length of phrenic nerve evulsed was 17 cm. The average rise was 4.8 cm. There was a better average rise of the left diaphragm by 0.6 cm. In 78 per cent the paralyzed diaphragm showed paradoxical movement.

Anatomic Changes in the Diaphragm Following Phrenicectomy—Stanbury gives an analysis of eleven necropsy cases of atrophy of the diaphragm following section of the phrenic nerve. In all but one case the operation of choice was evulsion by the method of Felix. The duration of the paralysis noted in the series varied from three weeks to six years. Atrophy of the diaphragm is evident as early as the third week after section of the phrenic nerve and is complete by the fourth month. After paralysis, one half of the diaphragm is elevated and eventrated into the thorax. With stretching it becomes a thin whitish membrane of parchment-like thinness. Histologically, the atrophy of the paralyzed half of the diaphragm is seen to be complete and uniform. In one case only, a few normal muscle bundles were seen in one area, scattered among atrophic fibers. This probably represents an accessory nerve supply rather than actual regeneration. In view of the marked distortion of the abdominal viscera in ten of the cases, three of which presented a fatal gastroduodenal obstruction, the possibility of such complications must be considered seriously when advising phrenicectomy for the treatment of pulmonary disease.

*Clinical Investigations on Summer Encephalitis in Japan S Naka S Kungo and K Kurowa—p 30

Summer Encephalitis in Japan—Naka and his associates point out that whether the acute encephalitis that occurs in Japan every year during the summer months is identical with epidemic encephalitis (Economo) is a disputed matter. They report their observations in seventy-six cases. They found that this form of encephalitis occurs only during the summer months. In this respect the disorder differs from the epidemic encephalitis described by Economo. The disease occurs for the most part among the poorer classes, whose houses are small and too warm. This type of encephalitis is also differentiated from epidemic encephalitis by the fact that it affects older persons (77 per cent were more than 40 years old) and small children primarily. It was revealed that approximately two thirds of the patients had passed through a disease that impairs the resistance of the brain or of the entire organism (cerebral hemorrhage, high blood pressure, nephritis, headaches, neuralgia, hydrocephalus, febrile diseases, general debility or congenital syphilis). The eliciting factor in 74 per cent of the cases was physical exertion during exposure to the summer heat. The prodromal stage lasts generally only one day, rarely two or three days, and in exceptional cases four or five days. The symptoms listed in the order of their frequency are headache, lack of appetite, general debility, nausea and vomiting, drowsiness and disturbed sleep. It is surprising that the sleep disturbances are comparatively rare. The disease usually begins with high fever, and the pulse is relatively slow. On the first or at the latest on the fourth day, the patient becomes delirious or comatose. After this stage either convalescence occurs or a condition of apathy supervenes. The psychic symptoms of this phase are total amnesia regarding the delirious phase, slow thinking, perseveration, apathy, astereognosis and various forms of aphasia. During this stage there frequently exists somnolence as the result of fatigue. In contradistinction to epidemic encephalitis, symptoms on the part of the cerebral nerves are comparatively rare. The pressure of the cerebrospinal fluid is normal or slightly increased. There is always a pleocytosis

(average about 60 cells per cubic millimeter) Phase I of the Nonne Apelt reaction is always positive. The course of this form of encephalitis is comparatively short. In patients who recover, the symptoms disappear in from nine to twenty eight days. The mortality rate is 63 per cent, death occurring between the fourth and twelfth days. The authors reach the conclusion that the Japanese summer encephalitis is a distinct disease entity which differs from acute meningitides, the epidemic encephalitis described by Economo, the encephalitis described by Strumpell Leichtenstern and alcoholic pseudo encephalitis. The symptomatology indicates that it is an acute inflammation of the midbrain and end brain or an acute panencephalitis.

Blood Picture of Summer Encephalitis in Japan—Matsumura and his associates made hematologic studies in thirteen typical cases of summer encephalitis. They found that the erythrocyte number is within normal limits. In the cases that take an acute course there are slight changes in the size and shape of the erythrocytes and normoblasts. The hemoglobin content averages 78.6 per cent. During convalescence the hemoglobin content is slightly reduced. The number of leukocytes increases. The degree of the increase corresponds to the severity of the disease process; it is highest during the severest stage of the disease. After this stage has passed, the number of leukocytes gradually decreases again. The neutrophil leukocytes are as a rule greatly increased, particularly during the severest stage. During convalescence they decrease again. The lymphocytes, however, are decreased during the severest stage of the disease and reach normal values during recovery. The monocytes are slightly below normal. The eosinophil leukocytes disappear or decrease noticeably during the height of the disease process, and the basophil leukocytes seem to be decreased. Plasma cells were found in only two cases. The average number of blood platelets is normal, but in severe cases their number seems to decrease at the height of the disorder and to increase during convalescence. The sedimentation speed of the erythrocytes is increased. The coagulation time, the bleeding time and the resistance of the erythrocytes show no noticeable changes.

Periostitis and Osteitis in Frambesia—Iseki observed two cases of jaws. One patient, a woman of 19, showed spindle-shaped swelling in the second segment of both her middle fingers accompanied by slight pain. The patient contracted the infec-

tion one year before from her child and then presented frambesic papules and afterward generalized papules, which were cured by three injections of arsphenamine. Six months later the papules returned, and about three months afterward the lesion appeared in the right hand, and in two months more it appeared in the left. Roentgen examination showed that both middle fingers were obviously thickened at the second segment, the shadow being especially well marked on the inner side. The right one presented slight swelling of the outer side of the bone. Also the first phalangeal joint of the left hand was affected. The other patient, a girl of 10, had the same spindle-shaped swelling in the first segment of the second finger of the right hand. She had suffered from frambesic papules for two or three months, and they were still to be seen. She presented swelling of the middle part of the left tibia, in which there was slight pain. There was also a frambesic papule on the left middle finger and one on the left joint of the knee. As these patients have been suffering from the early stage of framnesia with positive seroreaction and were healed readily by the administration of arsphenamine, the lesions may be safely regarded as being of frambesic origin. They may be considered as a periostitis and osteitis of the phalanges in the secondary stage and not in the tertiary (gummosis) stage. The cure, in the latter case, which is destructive in nature, is usually only slowly brought about through specific treatment.

- *Treatment of Myocardial Insufficiency by Dextrose and Combined Dextrose Insulin Guillaume—p. 529
Peripheral Facial Paralysis of Familial and Relapsing Type M. Schachter—p. 542

Treatment of Myocardial Insufficiency—Guillaume believes that the rationale of treating myocardial insufficiency by dextrose and insulin is sound. The utilization by the cardiac muscle of the increased supply of energy should be advantageous. In several cases good results were obtained, but a favorable outcome was not constant. Dextrose and insulin appeared to have an especially favorable action in cases in which the pulse showed alternation and in cases in which the electrocardiogram showed an inversion of the T wave in two leads. Even the results obtained in cases of angina pectoris were encouraging. In painful infections of the heart, however, this treatment was without action. The author states that the treatment is without danger to the heart and may be tried with impunity.

Choleraform Syndrome in Infections of Infancy—

Infantile cholera is a syndrome and not a morbid entity. Ribadeau-Dumas believes that the ratio of cell chlorides to plasma chlorides is a practical method of evaluating the changes in cellular ionic equilibrium. Thus normally in a child the cell chloride is 18 per cent and the plasma chloride 3.6 per cent, giving a ratio of 0.5. In the choleraform syndromes resulting from an infection this ratio is elevated. Coincidentally the renal function is disturbed, and oliguria, albuminuria and cylindruria appear. The blood urea is increased, it being common to observe 1 or 2 Gm. or more. In two children with the choleraform syndrome observed by the author the cell-plasma chloride ratio was 0.6. One patient recovered and the other died. He concludes that hyperchloremia may exist without modification of the cell-plasma chloride ratio. Under such circumstances dextrose solution is used to reduce the level of both the tissue and plasma chlorides. When the cell-plasma chloride ratio is increased, bicarbonate solution is used to reduce the level of both the tissue and plasma chlorides. When the cell-plasma chloride ratio is increased, bicarbonate solution is

used to reduce it. In children an isotonic solution is employed. Finally, in hypochloremia an isotonic salt solution is used.

Inhalations for Intoxication by Gases—Cordier believes that it is not logical to treat asphyxias without lesions of the lungs by the same method of therapy as those due to suffocating gases associated with serious pulmonary lesions. In acute phosphene poisoning, for example, the oxygen of the arterial blood and the saturation of the hemoglobin are diminished. The p_{H_2} also is progressively lowered. Likewise the proportion of free carbon dioxide in the plasma becomes higher than normal, especially at the moment of death. In the lung of a person affected with pulmonary edema due to a suffocating gas the volume of air that can circulate is naturally limited. Finally, the respiratory center in this type of poisoning is not deprived of stimulus, since the carbon dioxide content of the plasma is raised by the condition itself. In both types of intoxication there is therefore a lack of oxygen. In carbon monoxide poisoning, however, the free carbon dioxide is diminished. With these essential differences in mind the author concludes that in asphyxias without lesions of the lungs a treatment consisting of inhalation of oxygen, oxygen and carbon dioxide or air and carbon dioxide may be used. In those caused by suffocating gases, oxygen alone is capable of combating the anoxemia. Carbon dioxide mixed with oxygen or air can only serve to aggravate the acidosis, dyspnea, edema and asphyxia in conditions of this nature.

Important Point in Diagnosis of Operability of Cancer of Rectum in Man R. Leibovici and R. Soupault—p. 580

*Role of Neurovegetative System in Permanent Arterial Hypertension J. Olmer and J. Carbonel—p. 581

Enteralgic Crisis and Chronic Appendicitis—Jacquet describes a condition that differs from simple colic and in its acute rhythmic pain of several hours' duration justifies the name of enteralgic crisis. Morphine may attenuate the condition but does not interrupt it. The crises occur in series and in certain seasons of the year. Often they arise during the night accompanied by nausea, bilious vomiting, fever sometimes, and pain beginning in the right hypochondrium below the costal margin. Conforming to its colic character the abdomen is relaxed and palpation of the abdomen is only slightly painful, if at all. Violent pulsation of the abdominal aorta is usually visible and palpable. The crisis ends in the morning at the time when colonic digestion ends. It leaves the patients panting, prostrate and in a state of chill in the severe cases. After a short convalescence no signs of the attack remain. Various causes appear to be responsible at different times for this picture. Ptosis of the right colic angle, fecaliths and pericholecystitis have been determined in some instances. The most frequent cause is chronic appendicitis, sometimes, in fact, enteralgic crises are the only symptom of appendicular disease. Sensitivity of the appendix to pressure often arises only at the onset of a crisis and endures only a few hours after. Retrocecal appendices have been found in most of these cases that have come to operation. Of four with the appendix in the normal position, three were tuberculous. Tenderness to palpation was most marked over the ileocecal region. The author states that enteralgic appendicitis, regardless of anatomic form, offers an excellent prognosis from the operative standpoint.

Neurovegetative System in Hypertension—Olmer and Carbonel believe that epinephrine is the logical substance with which to test the role of the neurovegetative system. It is the product of secretion of the suprarenal medulla and is therefore physiologically allied to the neurovegetative system. Their technique is as follows. The arterial tension is measured with the oscillogram of Boullitte. Three successive measurements are made and the last is retained. Small doses of epinephrine (1 or 0.5 cc of 1:1,000 solution) are given intramuscularly. The tension and pulse are measured immediately after the injection, each minute for ten minutes, then every ten minutes for an hour, and finally every half hour until the pressure and pulse return to normal. This test was applied to twenty-four hypertensive and nine normal subjects. In two of the hypertensive patients the arterial tension was slightly increased

(1 cm of mercury) for forty and twenty minutes, respectively. In the twenty-two others a reduction of the blood pressure occurred. Of the nine normal persons, no notable change occurred in four, in five there was a diminution in arterial tension. Thus epinephrine produced in hypertensive persons an important and lasting reduction of the arterial tension, while the modification of pressure in normal persons was slight. In this differential action lies the proof of the derangement of the vegetative nervous system in hypertension. The authors conclude that, excepting perhaps in renal hypertension at the onset, the nervous system and vegetative metabolism are always disturbed in hypertensive persons.

*Rare Complication in Removal of Adenoids Case of Nasopharyngeal Torticollis Piotet—p. 355

Nasopharyngeal Torticollis—Piotet relates the history of a girl, aged 8, who after removal of the adenoids, felt severe pains in the left side of the neck. Examination revealed that the head was inclined to the left side, the cervical muscles were rigid and the slightest movement of the head caused pain. The temperature fluctuated between 37.8 C (100 F) and 38.5 C (101.3 F). The fever and the fact that the sternocleidomastoid muscle was neither rigid nor painful excluded the diagnosis of simple torticollis. After thorough examination, the author discovered a small retropharyngeal abscess from which pus was discharged. After two months of subfebrile temperature his patient recovered. He points out that besides the extreme cases, in which a luxation of the atlas takes place, there occur milder cases, in which a luxation does not take place. His case belonged to the latter group. As to treatment, he says that a recent luxation can be reduced by continuous extension by means of a special apparatus for the treatment of torticollis. If applied later, this treatment will have satisfactory palliative effects.

*Neosarsphenamine in Treatment of Typhoid C. Re—p. 555

Tonsil Investigation—By means of aspiration, Olivetti and Malan investigated the tonsils of fifty patients presenting nephropathies, polyarthritis, rheumatism and cryptogenic sepsis. Of the various generalized reactions following tonsillar trauma, the authors consider the changes in the leukocytes, preceded or not by leukopenia, signs of tonsillar involvement. The absence of quantitative variations would indicate that the tonsils are not affected. They preferred aspiration to tonsillar traumatism such as massage, rolling and thermic stimulations because, when produced by means of a suitable instrument, aspiration causes a constant traumatism in all cases and is a traumatizing maneuver which often rids the tonsils of numerous cheesy deposits. The authors first took a leukocyte count and then aspirated the tonsil for from thirty to forty-five seconds with a Worms-Le Mee glass pipet, the aspirating force being furnished by an electric motor of one-fourth horse power. After this the leukocyte count was taken every fifteen minutes for the first hour and every thirty minutes during the next two or three hours. In a number of patients in whom the test was positive the tonsil was the seat of a latent chronic infection. In considering the miniature focus resulting from aspiration, the authors accept the hypothesis of superinfection rather than reinfection, the reaccretion of disease symptomatology being interpreted on the theory of a renewed passage of germs through the old point of entry. The recrudescence of articular pains

hematuria or fever observed after tonsillar aspiration is important, especially when the disease of the patient did not previously indicate a focal origin. The authors emphasize the clinical importance of the curves showing absolute and relative neutrophilia. The curve indicating only leukopenia shows that the tonsils are not involved. All such patients presented an absolute neutropenia in addition to an absolute and relative lymphopenia.

Calcium Treatment and Glutathione in Tuberculosis—Baroni studied the behavior of reduced glutathione of the blood in twenty patients presenting pulmonary tuberculosis. The patients were given daily intravenous injections of 10 cc of a 10 per cent solution of calcium gluconate for ten consecutive days. The glutathione rate was estimated in blood taken immediately before treatment, after the fifth injection after the tenth injection and five days after the last injection. Of twenty patients, eighteen showed a marked increase in the glutathione rate, while two did not present any changes. After five days of suspension of treatment, sixteen patients showed increased values, three unmodified values and one lower values. After fifteen days, eleven patients showed stationary values and nine diminished values. The increase in the glutathione rate of 90 per cent of the cases, which was protracted during the days following the treatment, is attributed by the author to a reduction of intra-organic oxidative processes due to the calcium ion.

Neosphenamine in Treatment of Typhoid—Re states that the treatment of typhoid with neosphenamine should be tested on a large scale. The febrile period is shortened. This indicates that, when a rapid improvement of the general condition is evinced, the probability of complications diminishes proportionately and saves the defensive reserves of the organism. The treatment starts with a dose of 0.15 Gm of neosphenamine or, in robust individuals if thought necessary, 0.3 Gm. The preceding dose is repeated at intervals of from two to three days or the successive dose is increased. It is not possible in this regard to fix a rule, but attention must be given to the tolerance of the individual patients. Several authors have advised increasing the doses to 0.6 Gm, but the author never raised them beyond 0.45 Gm.

37 361 388 (April 7) 1934

*Desensitization by Autovaccines in Chronic Colitis H G Mogena — p 361
Meaning of Ammoniemia in Origin of Eclamptic Crisis J Botella Llusá — p 363

Desensitization by Autovaccines in Colitis—Mogena advises the use of autovaccines for the treatment of chronic spastic mucous colitis of bacterial origin. He obtains the organisms from the colon with the aid of rectosigmoidoscopy, the technic of which he describes. Cultures are prepared from the different types of organisms isolated from the colon and are killed by heat without the addition of an antiseptic. Intradermal injections of the cultures are given to the patient. The intensity of the reactions is observed one-half hour and twenty-four hours after the injection, and a vaccine prepared with the organisms whose cultures produce the most intense reactions. It is advisable to begin desensitization with small doses of the vaccine and to increase them gradually. Repeated small doses maintain the allergic condition. The author treated thirty-two patients suffering from chronic mucous spastic colitis and he was able to follow the results in twenty-six of the group. There was complete disappearance of the symptoms in sixteen cases, marked improvement in seven and failure in three. Two patients, in the group of three failures, probably had colitis of tuberculous origin because they reacted positively to the tuberculin test. Although the length of the treatment cannot be as yet determined, it is advisable to use the vaccines for several months in order to obtain complete desensitization. If the autovaccine treatment fails during the first few months, it is advisable to repeat the entire process and search for a new allergic reaction. New material is taken from the colon and new cultures and new intradermal injections are made. As a rule, the new cultures show the presence of other bacteria not previously observed, the vaccines from which give finally satisfactory results. The author used autovaccines, also in eight cases of advanced ulcerative colitis. The technic followed both

in the preparation and in the administration of the vaccines was the same as that used in cases of chronic spastic mucous colitis. In this group he obtained the following results. There was lasting improvement in one case slight improvement in two cases and no change in the remaining five. The author believes that these results are due to the fact that chronic spastic mucous colitis is of allergic origin (due either to alimentary or to bacterial allergens), while chronic ulcerative colitis is not of an allergic nature.

Treatment of Diffuse Peritonitis—Bretnier reports ten cases of diffuse suppurative peritonitis treated with the method of irradiating the intestine with ultraviolet rays during the course of the operation. The method was originated by Havlicek, whose purpose in irradiating the intestine during the operation was to study the circulation. Havlicek noticed that the convalescence of patients who had been irradiated was painless and brief. In the last three years he has operated in 108 cases of diffuse suppurative peritonitis without a death. The latest large statistics of Kirschner on diffuse peritonitis showed a general mortality rate of 47.7 per cent and for those of appendicular origin a mortality rate of 38.5 per cent. Havlicek removes the focus of infection, after which a coil of intestine is brought out if possible with its mesentery and the omentum. This is irradiated on either side with ultraviolet rays from a distance of about 35 cm, the procedure lasting from five to twenty-five minutes. Of the author's ten patients eight recovered and two died. The theory explaining the effect of the treatment is as follows. The patient with peritonitis dies, as a rule, because of cardiac failure. This failure is due to withdrawal of a large amount of blood that is stagnating in the splanchnic capillaries; the patient is said to bleed into his own splanchnic area. Irradiation of the intestine releases the histamine, the effect of which is to open the direct arteriovenous anastomoses and to raise the pressure within the portal vein. Circulation is thereby quickened, the minute volume is increased and the danger of cardiac failure is obviated.

Thrombo-Anguitis Obliterans—Hanser reports three cases of anguitis obliterans in patients whose ages were 43, 38 and 37 years. Death in the first case was caused by a morbid process in the coronary arteries identical with that causing gangrene of the right lower extremity. In the other two cases the coronary arteries presented the picture of anguitis obliterans. Sudden death in these cases was attributed to cardiac or coronary causes. The blood vessels of the extremities were not involved. The author considers anguitis obliterans a generalized inflammatory disease of the vascular system, and capable of localization. The process may involve internal blood vessels without simultaneous involvement of the extremities. The term "juvenile gangrene of extremities" is justified as a clinical concept, however, it represents only one manifestation of the generalized blood vessel disease of the organism when considered from the point of view of pathology. The concept that the disease is caused by suprarenalema and should therefore be treated by suprarenalectomy and sympathectomy meets with the objection that epinephrine, while narrowing the lumen of the blood vessels of various territories has the opposite effect on the coronary arteries and widens them.

Agranulocytosis After Treatment with Typhoid Vaccine—Schur reports a case of agranulocytosis with severe myeloid reaction in blood and spleen, which developed after treatment with typhoid vaccine. A review of the literature disclosed five other cases of changes in the blood following treatment with typhoid vaccine. In the first there developed a temporary thrombopenia and a hemorrhagic diathesis, in the second a mixed lymphatic and myeloid reaction, in the third a chronic lymphatic leukemia, in the fourth a chronic myeloma, and in the fifth, as in the reported case, an agranulocytosis. The literature describes two cases of neutropenia and lymphatic reaction following paratyphoid. From the fact that the typhoid toxin may cause various changes in the hematopoiesis from a simple thrombopenia to agranulocytosis with myeloid or lymphatic reaction and to chronic myeloma and lymphoma the author concludes that these disorders must be related and he emphasizes that investigations on the pathogenesis of leukemia should be considered in this regard. These observations have practical significance in that they prove the necessity of caution in the use of bacterial toxins, particularly typhoid toxins.

Treatment of Spinal Disturbances in Pernicious Anemia—Mester reports that in the treatment of the spinal complications of pernicious anemia he obtained good results with daily injections of a preparation containing liver, arsenic, strychnine and sodium glycerophosphate. He discusses the histologic aspects of the spinal changes that develop in pernicious anemia and reaches the conclusion that it is of vital importance to begin the treatment early.

Irradiation in Trigeminal Neuralgia—In a case of refractory trigeminal neuralgia Ausch resorted to treatment with the cold quartz lamp. In sixteen sessions the rays were applied from the outside at the infra-orbital foramen, as well as intra-orally along the entire right maxilla. The final result was complete freedom from pain, which has persisted for more than a year. The author employed this method in more than twenty cases and on the basis of his observations he concludes that the cold quartz lamp should always be tried before resorting to alcohol injection or to a surgical intervention in trigeminal neuralgia. Since July 1933 the author's method has been adopted by a clinic, and favorable results have been corroborated. He admits that ultraviolet irradiations in cases of trigeminal neuralgia are not new as such. The new aspect of his method is that the cold quartz lamp makes it possible to approach the second and third branches of the trigeminal from the oral side. The burner of the cold quartz lamp can be brought into direct contact with the mucous membrane.

Neuralgias and Chronic Myalgias—Benzur shows that neuralgia and neuritis frequently are not sufficiently differentiated. Pain may be the only symptom of a mild neuritis, but he thinks that only in this case can the two be identified. In most cases neuralgia is the symptom of a disturbance in some other part of the body, although neuralgias, particularly sciatica, may be caused by pressure on a nerve. The author considers that he is justified, however, in stressing the reflex neuralgias because the neuralgias and neuralgia-like pains that are not

caused by neuritis or pressure are reflex manifestations. He thinks that his opinion is justified in view of the fact that the pathogenesis, the course and the cure of many neuralgias and myalgias seem to be subject to the same laws as are the reflexes. The sudden appearance and cessation, the changes in intensity, the strong influence on the pain of external conditions such as cold, dampness and drafts, the frequent relapses and the high incidence during certain periods of life are further proofs for their reflex character. The author considers that the factors essential in the development of a reflex neuralgia or a reflex myalgia are a basic disorder that elicits the reflex, a high reflex response in the nerve or muscle, a high reflex response of the entire organism and an eliciting factor. After discussing these factors he points out that in the past the treatment of neuralgia and myalgia frequently considered only one symptom, the pain, without being aware of the real cause of the pain. It is necessary to determine whether the pain in neuralgia or myalgia is caused by inflammation or pressure or is reflex in nature. If the latter is the case, the underlying disturbance has to be determined and treated. Attempts should be made to reduce the general and local reflex response by such methods as improving the circulation or by psychotherapy. Moreover, the patient must avoid eliciting factors.

Treatment of Lupus Vulgaris—Richter combines the application of a tuberculin ointment with quartz lamp irradiation. In addition to concentrated tuberculin, the ointment contains killed but morphologically and chemically intact tubercle bacilli of the bovine and human types. To promote the antibody formation in the diseased area, quartz lamp irradiation was applied from a distance of 1 meter, beginning with a five minute exposure and gradually increasing by one minute each time. The surrounding areas were covered. It was assumed that the hyperemia and the resulting increase in the functional processes of the skin would increase the action of the tuberculin ointment. On the day following this treatment, a strong reaction with the signs of an acute inflammation was noted. As a rule, the treatment was repeated after five or eight days. After ten treatments a period of rest was given for from four to six weeks. If after that further treatment was necessary, a new series of treatments was started. Thus far, the author has employed the treatment only in patients with extensive and severe lesions. In two cases the treatment was a complete success, not a single lupus nodule remained and the extensive lesions had healed with a flat faintly red scar. In another case, considerable improvement was obtained. In two other patients only a few nodules remained after the treatment, and these were destroyed by means of electrocoagulation. Three other patients are still receiving treatment and in all the lesions show a tendency to heal. In two cases the treatment failed. The combined tuberculin and quartz lamp treatment was tried also in three cases of erythema induratum Bazin and cures resulted. A patient with papillonecrotic tuberculids on both legs was likewise cured.

 *Allergic Disturbances of the Eye J Urbanek—p 533

Therapy of Peptic Ulcer—Glaessner shows that the non-specific irritation therapy of peptic ulcer has not come up to expectations and that the results of the specific therapy that he and Loeper have introduced surpass those of other internal methods. The specific therapy consists in the subcutaneous or intramuscular injection of a neutral pepsin preparation. He gives thirty injections either subcutaneously or intramuscularly. The first ten injections are increasing amounts of pepsin, the next ten are equal amounts and the last ten are decreasing amounts. This series of treatments may be repeated after six months, because about this time relapses occur occasionally.

The pepsin therapy is combined with a dietary and a medicinal therapy. The diet is primarily lactovegetarian, but some meats and fish are permissible. The medicinal therapy consists in a dose of pure olive oil (20 Gm) to be taken before the meals and a bismuth preparation (bismuth carbonate, or bismuth subnitrate) after meals. The pepsin therapy may be employed in peptic ulcers of the stomach and duodenum and in ulcers of the esophagus and of the jejunum in which there are no irreparable changes. However, in cases of deeply penetrating ulcers that have existed for a number of years, cases presenting scar formations and severe stenoses, cases in which carcinomatous degeneration is likely or cases in which perforation threatens or there is severe hemorrhage pepsin therapy is inadvisable and surgical treatment is usually necessary. The author has employed the pepsin therapy in approximately 1,000 cases. The results were favorable in gastric and duodenal ulcers, esophageal ulcers likewise were improved, but in jejunal ulcers the results were not so favorable.

Allergic Disturbances of the Eye—Urbanek shows that the frequent demonstrations of tubercle bacilli in disturbances of the eye, particularly in cases of uveitis, prove that tuberculosis is the cause of many diseases of the eye. The fact that in a number of cases of keratoconjunctivitis a tubercle bacillema could be demonstrated indicates that the tuberculosis is the most prominent endogenous factor. As uncleanness of the skin is found in the majority of cases of keratoconjunctivitis, it is likely that an exogenous noxa enters the conjunctival sac and produces the eczematous keratoconjunctivitis. The author shows the analogy between anaphylaxis and tuberculin allergy and points out that the development of scrofulous keratoconjunctivitis requires, in addition to the general sensitization of the organism (tuberculin allergy), also a second, endogenous or exogenous, factor. He thinks that the exogenous local component is more frequent than the endogenous. He points out that scrofulous keratoconjunctivitis is particularly frequent among the poorest classes of people and he thinks that neglect is a factor in its development. During the years of starvation after the war, he noted that approximately 40 per cent of eye disorders were scrofulous keratoconjunctivitis, and nearly all of these patients had skin disorders. He observed a number of cases in which, on the basis of a tuberculous disturbance, the administration of tuberculo-protein was followed by the development of uveitis not only in the eye that had been diseased formerly but also in the healthy eye.

Glycogen Storage Disease—Biedermann and Hertz describe two cases of glycogen storage disease in children of school age. One of the boys was almost dwarfish, he had a eunuchoid accumulation of fat at the pubic eminence, and repeated bone fractures from slight causes indicated that there was a calcium deficiency of the skeleton. In the other one, the inhibition of the growth was less noticeable and the obesity involved the trunk. The urine was practically normal in both

cases. It was always free from sugar, urobilin and urobilinogen were never increased and bilirubin was absent. Microscopic examination of the feces and test meals revealed no disturbances of the digestive function. The stability of the serum colloids of the blood was altered, and the sedimentation speed of the erythrocytes was enormously increased. The width of Weltmann's flocculation band was changed and the fibrin content of the plasma was reduced. The authors point out that the history of the parents of children with glycogen storage disease frequently reveals treated syphilis and that other relatives occasionally show degenerative psychic changes. The patients themselves have never been found to be syphilitic.

Growth Disturbances in Glycogen Storage Disease—Hertz shows that in glycogen storage disease there occur various growth disturbances. There are the aspects of a dystrophy resulting from carbohydrate hunger and the aspects of incretory disturbances. These two types of disturbances may occur alone or together. The incretory disorders known thus far indicate a disturbance in the function of the hypophyseal mesencephalic system, but anatomic changes of the hypophysis have not yet been discovered in glycogen storage disease. However, local hypophyseal disturbances frequently are absent also in adiposogenital dystrophy and in a form of dwarfism, which is now widely assumed to be of hypophyseal origin. The author concludes that a familial constitutional deficiency of the endocrine system and of the organism on the whole is highly probable in glycogen storage disease but that the high incidence of hypophyseal and cerebral manifestations nevertheless seems to indicate a circumscribed neuro-endocrine disorder.

Children's Eczema and External Irritations—Becker and his associates employed various tests without being able to demonstrate a primary increased vasomotor sensitivity as a characteristic of the skin of eczematous children. From the localization of the eczema and from its dependence on a stronger blood perfusion, it could be determined that slight external irritations, which in noneczematous persons remain below the threshold of stimulation, produce a secondary irritation of the capillaries in eczematous persons. The resulting hyperemia is considered to be important in the pathogenesis of eczematous changes. The cantharidin test was performed in order to determine whether a superficial erosion of the epidermis heals differently in the eczematous person than in the one without eczema. In seborrheic dermatitis, it revealed retardation of the healing process and increased desquamation, congestion and infiltration. The dermatosis and the reaction could be modified by alimentary measures, and thus the underlying metabolic nature of the cutaneous disturbance was revealed. The reactions observed in eczema indicated that, aside from the pathogenomic congestive-exudative component, a dyskeratotic factor is involved. In eczema the reaction is not of primary alimentary origin, as it is in seborrheic dermatitis, but is caused by a nutritional disturbance produced by inflammatory impregnation of the epidermis, which becomes more evident when the skin is inclined to desquamation. In neurodermatitis the cantharidin reaction is frequently weak and similar to that of the noneczematous person. This is due to the spastic condition of the cutaneous vessels, as the result of which a single irritation by cantharidin is not capable of producing the permanent hyperemia, which in turn is the basis for the pathologic form of the reaction. Normal reactions are obtained in cases of milk crusts, supporting the opinion that the condition is localized. The authors think that the epidermis is impaired by the exudation and that the products of the disordered epidermal metabolism increase the irritability of the vessels.

Death from Eclampsia—Caffier thinks that death in eclampsia may be due to (1) asphyxia of central origin, which

in turn is caused by vascular spasms in the region of the respiratory center, (2) involvement of the heart in the tonic phase of the eclamptic attack, (3) spasm of the coronary vessels of the type that causes death in angina pectoris, (4) shock, caused either by an alteration of the center of the vagus by vascular spasm in the medulla oblongata or by an irritation of the pulmonary branches of the vagus during the tonic phase of the eclamptic attack. The postmortem examination of a woman who had died during the attack showed the heart in maximal systole. This would indicate the second mode of death listed by the author. Two other patients did not die during the eclamptic attack, but a severe cardiac disturbance developed with the eclamptic attack and was the cause of death. The postmortem examination revealed pathologic changes in the cardiac conduction system. The author thinks that the heart should be given careful attention during an eclamptic attack. He discusses a group of fatal cases of eclampsia in which characteristic renal changes were found. In all of them the amount of the functioning renal parenchyma was reduced so that practically only one kidney was functioning. The author thinks that the eclampsia takes an especially severe course in such cases.

Rapidity of Exchange of Amniotic Fluid—In studying the exchange of the amniotic fluid, Albano injected 6 mg of sodium phenolsulphonphthalein into the amniotic cavity. Since the phenolsulphonphthalein begins to appear in the maternal blood about one hour after the injection, observations on the resorption were begun at this time. Specimens of amniotic fluid were withdrawn at intervals of several hours and the quantity of phenolsulphonphthalein was determined by means of the colorimeter. The studies were made on women who were near the end of pregnancy, some were healthy and some had polyhydramnios. However, the author thinks that the studies should be made also during the earlier period of pregnancy (up to the fourth month). His investigations revealed that toward the end of pregnancy the capacity of the amniotic cavity is 675 cc. The resorption of the amniotic fluid takes place with a rapidity of 47.25 cc per hour or 0.783 cc per minute. The entire quantity of fluid is renewed in about 14.31 hours. It was found that the values determined by theoretical computation correspond to the real values, and thus it is possible to determine the resorption value at any moment of the observation period. The author thinks that the knowledge of the physiologic condition may serve as a basis in the study of pathologic conditions in the exchange of the amniotic fluid and may aid in the early diagnosis of such disorders as polyhydramnios, compensated cardiopathies, tuberculosis, death of the fetus and gestosis.

*Occurrence of Follicle Stimulating and Luteinizing Factors of Anterior Pituitary Like Principle in Urine of Women Castrated by Roentgen Treatment or by Operation. H. C. A. Lassen and E. Brandstrup—p. 89

Cutaneous and Mediastinal Emphysema in Parturient Women—Turunen reports two cases of young, healthy primiparas in whom, after comparatively easy deliveries, cutaneous emphysema developed in the upper part of the body, especially on the right side. In one case a roentgenoscopy of the thorax showed that the mediastinum likewise was emphysematous. This is the first report in which this condition has been noted with cutaneous emphysema. Clinical examination revealed that the cardiac dulness was absent for several days, furnishing additional proof that mediastinal emphysema existed. It was probably the result of a subpleural tearing of the pulmonary tissue. Consequently it may be assumed that, in cases of cutaneous emphysema developing in connection with delivery, the air comes from a pulmonary rupture, enters the mediastinum

and gains access to the skin. Since this complication is extremely rare and since it could be caused by the amount of exertion necessary to normal labor, it must be assumed that anomalies of the respiratory tract or abnormal weakness of the pulmonary tissues favor its development. The author thinks that mediastinal emphysema may occur more frequently during delivery than is generally assumed but that it rarely is extensive enough to produce cutaneous emphysema.

Follicle Stimulating and Luteinizing Factors of Anterior Pituitary Like Principle in Urine of Castrated Women—In a series of women who had been subjected in thirty-six instances to roentgen castration and in ten instances to surgical castration, Lassen and Brandstrup made a total of 436 tests for anterior pituitary-like principle in the urine. The tests were made once a month for from three to thirty-one months. With the technic employed, anterior pituitary-like principle could be demonstrated only when 1 liter of urine contained in excess of 400 mouse units. In the women who had been castrated with roentgen rays, the reaction for the follicle-stimulating factor of anterior pituitary-like principle was positive in approximately 30 per cent of the urine specimens (343) examined. The reaction for the luteinizing factor of anterior pituitary-like principle was positive in 7 per cent of the specimens. The incidence of the reaction for the former factor was practically the same throughout the observation period, but the reaction for the latter factor was positive most frequently during the first half year after castration. Of the roentgen castrates, 92 per cent excreted the follicle stimulating factor of anterior pituitary-like principle in amounts of over 400 mouse units per liter at some time during the observation period, while a similar amount of the luteinizing factor of anterior pituitary-like principle was detected in 44 per cent of the cases. In the surgical castrates a positive reaction for the follicle-stimulating factor of anterior pituitary-like principle was obtained in about half the urine specimens examined, while the reaction for the luteinizing factor of anterior pituitary-like principle was positive in about 9 per cent of the specimens. The reactions for anterior pituitary-like principle are most frequent during the first six months after the operation. All ten patients excreted at some time or other after the operation the follicle-stimulating factor of anterior pituitary-like principle in amounts of more than 400 mouse units per liter of urine, most of them within the first half year after the operation. Six patients gave a positive reaction for the luteinizing factor of anterior pituitary-like principle within that period. In suitable control material less than 15 per cent of the cases gave positive reactions for the follicle-stimulating factor of anterior pituitary like principle and the reaction for the luteinizing factor of anterior pituitary-like principle was positive in from 1 to 2 per cent of the cases. Tests were made also (one in each case) on sixty-three women of the menopausal age and the reaction for the luteinizing factor of anterior pituitary-like principle was positive in 14 per cent of the cases.

*Adipose Necrosis in the New-Born. H. Harpøth—p. 369

Adipose Necrosis in the New-Born—Harpøth reports a case of necrosis of the fatty tissue in an infant. Subfebrile temperature and a disturbance of the skin and subcutaneous tissues of the buttocks were noted two or three days after birth and a slowly progressive dry necrosis with undermined edges. Death occurred after seven weeks. There was infiltration of the skin 5 cm outward from the edge of the necrosis. The author says that sclerema neonatorum includes sclerema adiposum, sclerema edematosum and necrosis adiposum neonatorum. The first two diseases are excluded in this case. The results of the microscopic examination agreed in the main with those in Gelberg-Hansen's case. The condition was characterized by indistinct boundaries of fat cells and reactive infiltration of giant cells. This is believed to be the second report of superficial adipose necrosis.

WHAT IS A NORMAL PELVIS?

HERBERT THOMS, MD
NEW HAVEN, CONN

It may be surprising at first glance that the question of what constitutes a normal female pelvis should be presented as a subject for consideration. However, in the light of recent studies, I am of the opinion that this query does offer a basis for serious discussion.

In modern textbooks on obstetrics the normal female pelvis is differentiated from the normal male pelvis by characteristics of size and shape, which are generally recognized and which do not require delineation. One of the chief differences noted is the shape and size of the superior strait or inlet. In the normal male pelvis this plane is described as more or less round, with practically equal anteroposterior and transverse diameters. On the other hand, in the normal female pelvis the plane of the superior strait is described as more oval, the transverse diameter averaging 13 cm and the anteroposterior 11 cm.

Four facts have a bearing on this query. In the first place the superior strait of the fetal and of the infant pelvis in the two sexes is similar. It is round or even presents a longer anteroposterior than transverse diameter. In the second place the adult male pelvis retains much of the fetal shape, the pelvic inlet being round with diameters of approximately equal length. In the third place the adult female pelvis of many aboriginal races retains much of the fetal conformation in the shape of a round pelvis. Finally, in white women in the United States the incidence of the round pelvis, and of pelves whose longest diameter of the inlet is the anteroposterior (the so-called anthropoid type) is far greater than has been hitherto suspected.

Because of these facts it appears, first, that possibly the material for study, from which the definition of the so-called normal pelvis has been derived has been insufficient for proper evaluation and secondly, that the so-called normal or oval pelvis is the result of the influences of civilization rather than those of race or sex. The fact that aboriginal races have easy labors is well established. If it is true that these women in general possess the round type of pelvic inlet it is at once clear that the round fetal head fits such a pelvis to far greater mechanical advantage than obtains in the "oval" pelvis of their civilized sisters.

In Jarcho's¹ recent review of the literature on this subject the following statement is made:

On the basis of comparative findings two types of pelves may be distinguished:

1 The round pelvis in which the conjugata vera is as long or nearly as long as the other two diameters of the inlet. This

From the Department of Obstetric and Gynecology Yale University School of Medicine.
1 Jarcho, Julius. The Pelvis in Obstetrics. New York: Paul B. Hoeber, 1933. p. 58.

type is found in the aborigines of America, Australia, and the East Indies.

2 The oval pelvis, in which the conjugata vera is more than one-tenth less than the other diameters of the inlet.

Upon studying the mass of statistics presented in Jarcho's work one is impressed with the comparatively small number of studies made on the fresh or the dried pelvis and the comparatively large number of data that have been derived from reviewing external pelvic measurements. With regard to the determination of the size and shape of the pelvic inlet by external pelvimetry, I would refer the reader to my recent communication² in which the fallacy of such a procedure is exposed by roentgenometric study. Prior to the employment of roentgenometry in obstetrics, exact information regarding the size and shape of the pelvic inlet in living women was not available.

It is probable, therefore, that roentgenometry will reconstruct views with regard to the characteristics of the female pelvis. That this has already occurred to a degree is witnessed by the unusual incidence in the population of what have been termed the "male" type and the "anthropoid" types of pelves emphasized by Caldwell and Moloy in 1933,³ and by me in 1932,⁴ 1933,⁵ and 1934.⁶ The round or "male" type, and the elongated or "anthropoid" types of pelves, as I pointed out in 1932, are definitely associated with both primary and secondary occiput posterior positions. That these positions are frequently met during labor is shown not only by my own studies but by those of Pride,⁷ who found in a roentgenologic study of 250 cases that at the beginning of labor the occiput was directed posteriorly three times as frequently as it was anteriorly.

Interesting, too, are the observations of J. T. Williams,⁸ who in speaking of variations in types of female pelves divides them into "feminine" and "muscular" types. The increase in the incidence of the occiput posterior position and the narrowing of the pelvic outlet noted in the latter type of pelvis, are observations which correspond in general to my own observations in the "male" and the "anthropoid" types of pelves.

In a study in which I am now engaged there have been observed to date fifty consecutive primiparous patients, of whom twenty-three possess either the round or the elongated pelvis already referred to. I believe, therefore, that female pelves corresponding to the type seen in primitive women occur with far more frequency in women of this country than has hitherto

been suspected. The question at once arises as to which is the normal pelvis, the round or the oval type.

Stoney⁹ and Vaughan¹⁰ have suggested that oval pelves are not truly the result of racial influence but are caused by the conditions of life in modern civilization. The former says that the oval pelvis of the civilized woman is due to lack of light and vitamin D. Vaughan emphasizes the causal relationship of other factors such as posture (especially in children) and points out that differences in pelvic development may be noted in the same race living under different conditions. Thus, women of India and China who work outdoors have easy labors, while those living in cities or in seclusion have difficult labors. Jarcho¹¹ quotes the Carnegie Trust Report for 1917, which emphasizes the "easy labors and large families among the Highland women who, barefooted, haul in the nets with the men, follow the plough and engage in field work." Incidentally, I may add that their diet probably consists largely of fish, which is a well known source of vitamin D.

The effect of civilization on an aboriginal people living under poor hygienic conditions in large cities is nowhere better shown than in the studies of J. Whitridge Williams,¹² who emphasizes the effect of such an environment in producing rickets and imperfect general development which play so conspicuous a part in the genesis of abnormal pelves in the colored race.

Miller,¹³ in speaking of Williams' studies of rachitic pelves in the Negro women of Baltimore, makes the comment that

he [J. W. Williams] works in a city which is essentially Northern in mode of life and his patients live in tenements and in typical tenement surroundings, whereas the Negro of the far South both in the city and the surrounding country, whatever else he may lack has an abundance of fresh air and sunshine, the two arch enemies of rickets. Levey's report from the Touro clinic I might add corroborates these findings as to the relatively small percentage of contracted pelves among colored women in this part of the country.

In view of the facts that the so-called simple flat pelvis is frequently regarded as of rachitic etiology and that there is a great prevalence of at least the mild manifestations of rickets in the population, as witnessed by the excellent studies of Eliot¹⁴ for the Children's Bureau, it is not difficult to see how the lesser grades of flattening of the superior strait could occur. Furthermore, it is not difficult to imagine a more or less general production of the oval type of pelvis.

The observations of Hess and his associates¹⁵ are pertinent. These authors state that

Although the incidence and severity of rickets in the United States has decreased in the last five or ten years, it must not be thought that it has become a negligible disorder. A clinical survey of rickets which we carried out this winter [1930-1931 in New York City] among the poor who attended health stations showed that fully half the white infants and approximately three fourths of the Negro infants have definite signs of rickets.

The various facts that I have enumerated suggest two interesting points, both of which are, of course, entirely speculative. First, the lack of the opportunity

now provided by roentgenometry, of studying accurately a great number of pelves in living women prevented our predecessors in obstetrics from securing satisfactory data for the proper evaluation of the normal or standard pelvis. Second, the predominant type of pelvis which was formerly seen in clinics may have actually changed in character within a generation. When alterations are considered in environment surrounding female infants and adolescent children during the past twenty-five years, changes brought about not only by a great difference in diet, but by such influences as outdoor exercise and life in the open, it must be admitted that the environment for this group has changed indeed during that period. When one further considers the sedentary habits, the type of clothing, the diet and general restrictions that previously were a part of the life of female infants and children, may one not speculate as to the effect of such an environment on the adult form of the female pelvis? That changes in environment can affect skeletal changes in a large proportion of a population is witnessed in recent years by the extraordinary lessening of the incidence in children of severe rachitis.

CONCLUSION

As present-day studies of the pelvis, greatly aided by roentgenometry, increase, it is assured that a definite answer to the original question will be found. At the present time it would appear, from a purely obstetric point of view, that the adult female pelvis is preferably round rather than oval. It may be, therefore, that the query has already been answered by the pragmatism of nature.

New Haven Hospital

THE MEDICAL CARE OF PATIENTS FOLLOWING TOTAL THYROIDECTOMY

EUGENE C. EPPINGER, M.D.

AND

SAMUEL A. LEVINE, M.D.

BOSTON

Total thyroidectomy has been proposed by Blumgart, Levine and Berlin¹ as a method of treatment in certain forms of intractable heart disease. There naturally have arisen some objections to this apparently drastic procedure, particularly in regard to the thyroprivia and its sequelae. Our purpose in this report is to consider the aftercare of patients subjected to complete thyroidectomy, especially the treatment of myxedema. Because requests have been received from physicians asking for specific details of postoperative management and because in some instances patients have been dismissed from some hospitals shortly after the operation without further attention, this discussion appears to be timely. As patients both with angina pectoris and with congestive heart failure have been subjected to this operation, the postoperative management of the two conditions will be dealt with separately.

In those with angina pectoris, who as a rule do not have evidences of cardiac decompensation, the convalescent period following operation is usually short, uneventful and unattended by troublesome complications.

From the Medical and Surgical Clinics of the Peter Bent Brigham Hospital.

These patients often are allowed to become ambulatory forty eight hours after operation and are permitted to leave the hospital from seven to ten days following operation. However, in this group the likelihood of sudden and unexpected death from coronary thrombosis or ventricular fibrillation is a constant menace. This risk may be aggravated by the emotional stress in anticipation of surgery or may be provoked by the operation itself. Fortunately, such a complication was a rare event in our cases. Within a period of four to eight

Chart 1—Progress of a patient with angina pectoris. Note the fall in blood cholesterol and the rise in the basal metabolic rate following thyroid therapy (0.030 Gm daily for one week and 0.015 Gm daily thereafter).

weeks following operation the typical symptoms and signs of myxedema will almost invariably develop and require treatment.

It has been shown that the administration of thyroid extract to elderly arteriosclerotic individuals with myxedema² may induce attacks of angina pectoris or precipitate congestive heart failure and occasionally coronary thrombosis. Although on several occasions thyroid feeding has failed to reproduce attacks of angina after surgical myxedema, such dangers are imminent, and the necessity of cautious administration of the extract is obvious. A safe rule is to give 0.030 Gm of the desiccated gland³ daily for one week and to continue with a maintenance dose of 0.015 Gm daily. The actual maintenance dosage should be determined by appropriate amelioration of the symptoms of myxedema, due regard being given to any possible untoward effects that the dosage might have on the circulation. In a very few instances, 0.015 Gm of thyroid extract daily was not adequate and a slightly larger dose was necessary, but in general it will be found that small doses are more effective in these thyroidectomized patients than in the ordinary spontaneous myxedema encountered in practice. A typical postoperative course is graphically depicted in chart 1.

The aftercare of patients operated on for the relief of congestive heart failure presents a more complicated problem in therapeutics, particularly in its relation to the management of myxedema. The postoperative convalescence was necessarily longer than in the group with angina pectoris and depended on two factors: first, the degree of decompensation at the time of operation and, second, the rapidity of the circulatory response to the deprivation of the thyroid secretion. In cases in

which cardiac compensation could be restored previous to operation by the usual medical measures, the period of convalescence in the hospital following operation was not longer than two or three weeks. After discharge, the medical regimen customarily employed in the treatment of chronic heart failure should be continued. The amount of physical effort to be permitted will naturally vary in different cases. In the group in which prolonged medical care failed to reestablish compensation and in which total thyroidectomy was done to lower metabolic demands to a level compatible with the lowered efficiency of the circulation, a much longer period of hospitalization was necessary. The full beneficial effects of the thyroidectomy did not become apparent until three or four weeks after the operation. When both signs and symptoms of heart failure disappeared, the patients were allowed to become ambulatory. As in the less seriously decompensated group, full digitalization should be maintained and a strict medical regimen observed. Occasionally it was found that less digitalis was necessary after than before operation. The eventual myxedema was effectively alleviated by thyroid extract in dosages similar to those outlined for the cases of angina pectoris. This regimen raised the basal metabolic rate from about minus 30 to a level of about minus 20, where it should be kept. A satisfactory course is shown in chart 2.

It is in this group with cardiac failure that the administration of an excessive amount of thyroid extract should be scrupulously avoided. The rise in the basal metabolic rate and the development of congestive failure can be quite rapid even on small doses of thyroid extract. This is well illustrated by the following case (chart 3).

A Negro, aged 52 with hypertension, chronic myocarditis and chronic auricular fibrillation was operated on for the relief of intractable cardiac failure. With the subsequently lowered metabolism, compensation was restored and he was able to lead a comfortable life until myxedema appeared. At this time he was given thyroid extract in doses of from 0.030 to 0.045 Gm daily. Within a period of fifteen days his basal

Chart 2—Progress of a patient with mitral stenosis, auricular fibrillation and refractory congestive heart failure. Note the marked fall in heart rate parallel to the fall in the basal metabolic rate after operation and the subsequent rise in both on thyroid therapy.

metabolic rate reached a level of 0 per cent and decompensation abruptly recurred, as manifested by a marked rise in pulse rate, pulmonary and peripheral edema, orthopnea and Cheyne-Stokes respirations. The basal metabolic rate rose still further after the thyroid extract was omitted, but then there was a rapid return to the previous state of compensation, which is still maintained eight months after the operation.

Myxedema has been the inevitable consequence of total thyroidectomy in all instances that were adequately followed. As a rule, the degree of myxedema was not

J. 195: 351 (Aug. 19) 1926. Means J. H. White P. D. and Kranitz C. I. Observations on the Heart in Myxedema with Special Reference to Dilatation and Angina Pectoris. *ibid.* 195: 455 (Sept. 2) 1926.

³ Armour's thyroid extract was used in this study.

marked. The symptoms complained of were puffiness of the face, lassitude, muscular pains, dryness of the skin, arthralgia, and gain in weight. In some cases, determinations of the basal metabolic rates were not reliable indexes of the degree of myxedema. Checks such as the velocity of blood flow⁴ and elevation of the blood cholesterol⁵ are occasionally helpful in guiding the course of therapy. When such measurements cannot be made, observations of the clinical status of the patient at appropriate intervals will serve sufficiently well to regulate thyroid medication. An example of such a discrepancy is a patient with angina pectoris without congestive heart failure whose basal metabolic rate was plus 1 per cent but in whom the evidences of myxedema were unmistakable. The velocity of blood flow was found to be 40 seconds and the blood cholesterol 610 mg per hundred cubic centimeters of blood. Thyroid therapy was given with beneficial results. Anemia was not encountered in our patients, probably because of the short duration of the myxedema. The association of psychosis with the hypothyroid state was encountered on only one occasion. This was in a patient with valvular heart disease and advanced congestive failure whose condition was but little improved by total thyroidectomy. There was no improvement in

three weeks. In no instance were the symptoms of sufficient severity to demand parathyroid extract. After treatment there were no recurrences.

Injury to the recurrent laryngeal nerves may occur as a result of surgical trauma and is indicated by hoarseness and possibly aphonia. Hoarseness appeared in a few cases and persisted for a variable length of time, but as yet aphonia has not been encountered. There is no specific treatment for this complication.

SUMMARY

In the postoperative care of patients subjected to complete thyroidectomy, there are three complications with which the physician is concerned: 1. Hoarseness and aphonia as a result of injury to the recurrent laryngeal nerves was very rare and required no specific treatment. 2. Postoperative tetany was quite uncommon, was never severe and was relieved by the administration of viosterol and calcium. 3. Mild symptoms of myxedema occurred almost invariably, were not necessarily paralleled by a low basal metabolic rate, and could be controlled easily by thyroid medication.

It was generally desirable to keep the metabolic rate at a level of about minus 20.

It was found that smaller doses of thyroid extract were necessary to produce the same effect in surgical myxedema than in the spontaneous type.

Finally, these patients should be given the same sort of medical advice as is given to cardiac patients in general, except so far as improvement permits an increased range of activity.

SIALOLITHIASIS

PAUL W. GREELEY, MD
WINNETKA, ILL.

In searching for causes of pain, swelling and inflammation around the mouth and cheeks, the average practitioner frequently overlooks salivary calculi, because he rarely sees one.

As uncommon as salivary calculi are thought to be, one may be surprised at some figures quoted. Harrison¹ made a careful search of the literature from 1825 to 1926 and found 375 reported cases. He added twenty seven of his own. When salivary calculi are found in the duct, they are usually oval or olive shaped, if formed in the gland, they are more apt to be round or irregular. They are usually single, but one author reports the removal of fourteen stones from one gland and its duct. Stones weighing as much as 236 Gm have been reported. This particular calculus measured 1 3/4 inches long, 1 inch wide, and one-half inch thick. Bush states that these concretions may vary in size from a millet seed to a walnut. Owing to the difference in their composition, the weight is not always proportional to the size.

One case was noted in the literature as occurring in an infant less than 1 month old. They are more common in males than in females. In about 75 per cent of all reported cases of salivary calculi the stones were in the submaxillary ducts or glands, about 20 per cent in the parotid and a small number in the sublingual ducts or glands.

Chart 3.—Rapid development of marked congestive heart failure (indicated by the black triangle) as a result of thyroid therapy (from 0.030 to 0.045 Gm. daily). Compensation was readily reestablished when the thyroid extract was omitted.

the psychosis following thyroid therapy, and the psychosis might equally well be attributed to the effect of prolonged cardiac decompensation. In general, with the initiation of thyroid medication the signs and symptoms of myxedema were promptly controlled and in our experience easily maintained by the regimen previously outlined.

Tetany was an infrequent complication of the operation and, when evident, the symptoms and signs were mild, such as stiffness of the hands, paresthesias and muscular weakness. Trousseau's sign was invariably positive when tetany developed, but Chvostek's sign was found to be less reliable. When tetany occurred, it appeared within four to fourteen days after the operation and was readily controlled by the administration of from 5 to 10 drops of viosterol and from 4 to 8 Gm of calcium lactate daily⁶ for a period of from two to

Badanes³ believes that three principal substances contribute to their formation, namely, calcium oxalate, globulin and mucin.

Calcium oxalate enters into the formation either as a foreign constituent from some fruits or vegetables rich in oxalates, such as asparagus, rhubarb and tomatoes, or as a salivary constituent in disorders of metabolism from a pathologic condition, or as a result of faulty nutrition.

Globulin, which is always present in the saliva mostly from the parotid secretion, is held in solution by the aid of the various salts present. Globulin is distinguished from albumin mainly by its insolubility in water. It may be precipitated from the saliva by weak acids or alkalis or a concentrated solution of neutral salts. It is also precipitated from a solution when diluted with pure water. The water one drinks with food precipitates globulin. In the churning act, while a bolus for deglutination is formed a small part of globulin, together with mucin and precipitated inorganic salts, is pressed into inaccessible places, where it finds protection as in the gingival trough around the necks of the teeth and, unless removed by chemical or mechanical means while fresh and still soft, will remain until it hardens in the course of time.

Mucin is a glucoprotein, formed from mucigen, which is found as granules in goblet cells of secreting glands. It forms the chief constituent of the cementing substance between epithelial cells. In the saliva it exists as potassium mucinate in solution. Like globulin, mucin is precipitated from solution by weak acids which have a pH range of about 1.5 to 4.9. It may also be precipitated from the saliva by strong alcoholic beverages. Mucin, in its precipitated form, swells up and is insoluble in water. It is soluble in weak solutions of neutral salts, such as chloride, sulphates and phosphates of sodium and magnesium, and will not be precipitated in their presence by acetic acid. A concentrated solution of sodium chloride renders sodium mucinate less soluble. Mucin dissolves in very weak solutions of alkalis, including lime water, but as calcium mucinate it is less soluble than as potassium or sodium mucinate.

Calcium carbonate and phosphate stones are sometimes formed around a foreign body nucleus.

SYMPTOMS

The symptoms vary. Some individuals may go for years without symptoms. There may be periodic attacks of colicky pain in the gland or duct involved. This is produced by retention of saliva and is accompanied by varying amounts of pain and discomfort in the region of the affected duct or gland, usually occurring immediately on eating or at the sight of food. The pain may be severe, especially when the patient attempts to swallow. A painful enlargement may occur, especially at mealtime. This may recede slowly, or, if the stone slips out of the duct so as to reestablish adequate drainage, the swelling may quickly disappear, at which time the patient may notice a sudden gush of saliva into the mouth.

Marked inflammatory symptoms may occur. If from prolonged blocking of the duct or for any other reason infection occurs, the mass may become tender, painful, red and swollen. Pus may be seen coming from the opening of the duct. A foul taste in the mouth, most frequently noticed after a night's rest, sometimes occurs

when the stone causes a continuous low-grade infection within the gland or duct.

DIAGNOSIS

Usually the diagnosis of salivary calculus is easily made from the history, supplemented by bimanual palpation and roentgen examination.

It is questionable whether probing a duct as a diagnostic procedure is warranted, since the duct may be perforated during the procedure. If it is necessary, a method described by Blair seems simple. A hypodermic needle filled with a local anesthetic solution infiltrates the tissues around the duct as the needle is passed in an effort to locate the stone. The needle or sound may touch the calculus and produce a grating sensation. Occasionally the stone may be seen spontaneously extruding from the orifice of the duct.

Since salivary calculi are usually rich in lime salts, they can be easily roentgenographed. Hamlin⁴ believes that negative reports are often the result of faulty technique. A calculus in the anterior two thirds of Wharton's duct can be readily demonstrated by using a $2\frac{1}{2}$ by $3\frac{1}{4}$ inch film placed horizontally between the teeth as far back in the mouth as possible, and by directing the rays from beneath the chin upward. A calculus in the posterior third of the gland itself will be best shown by taking a lateral view. The anterior two thirds of the duct cannot be demonstrated by a lateral picture because the duct will be obscured by the shadow of the mandible. Those in Stenson's duct can usually be shown on a small film held over the outside of the duct and parotid gland on the cheek.

DIFFERENTIAL DIAGNOSIS

Swelling of the parotid salivary gland must be differentiated from the following conditions: Benign tumors such as fibromyoma, endothelioma and teratoma are encapsulated, grow slowly, lie alongside the parotid gland, shell out easily and, if removed, do not recur. They may become quite large in years, if left alone. Carcinomas and sarcomas grow rapidly and soon involve the whole gland. They extend deeply among important structures such as the facial nerve and may cause facial paralysis. Swellings of the preauricular lymph glands due to pyogenic infection and syphilis must also be excluded. Mumps must not be forgotten.

Tumors of the submaxillary and sublingual glands are similar but more rare than those which occur in the parotid gland. Ranulas and mucous cysts of the floor of the mouth rarely offer much diagnostic difficulty. Lymphadenitis due to infection in the teeth or tonsils is frequently confused with sublingual or submaxillary enlargements. A careful history of the symptoms and examination as already described, together with roentgenograms of the teeth, will usually be adequate to rule out swellings due to dental origin. Ludwig's angina must also be remembered.

Mikulicz's syndrome is characterized by bilateral chronic swelling of the parotid or submaxillary or sublingual salivary glands. There may be a simultaneous swelling of the lacrimal glands. The spleen and lymph glands may also be enlarged. The syndrome is not due to a specific disease but usually results from lymphatic leukemia or less often from some infection such as tuberculosis, secondary syphilis or gout. Each of these

³ Badanes, D. B. Magnesium: An Aid in Preventing Calculus Formation. Dental Cosmos 71: 251 (March) 1929.

contributing factors can be easily ruled out by the proper diagnostic procedures

PROGNOSIS

Salivary calculi may recur, as shown in an article by Boss.⁶ Recurrences after operative removal are noted most frequently in the submaxillary and sublingual glands and ducts. The period between operative removal and recurrence has been noted to vary from a few months to five years. A recurrent attack may be due to (1) failure to recognize concretions of the excretory ducts of the salivary glands at operation during which these are often forced into the ducts, (2) breaking the calculus during removal and (3) transitory or permanent cicatrization of the salivary passages after removal of a stone without simultaneous extirpation of the gland. The universal preoperative use of roentgenography should localize and identify these calculi accurately so that all can be removed at the operation.

TREATMENT

The treatment may be medical or surgical or a combination of the two.

The essential medical methods include anything that will stimulate the salivary secretion. Belladonna in all forms should obviously be avoided. Simple massage of the duct may remove a stone if located in the anterior third. If acute inflammatory conditions exist, continuous hot fomentations and frequent oral irrigations with antiseptic washes should be carried out until such processes have subsided.

As stated earlier in this paper, mucin and globulin are both soluble in magnesium salts. Badanes⁷ believes that, by incorporating 0.5 per cent each of magnesium chloride and magnesium sulphate into any good toothpaste, globulin, mucin and even calcium oxalate may be dissolved. Although these two salts have a slightly bitter taste, they may be easily disguised by the sweet taste of glycerin and aromatics used as flavors in toothpaste.

INDICATIONS FOR OPERATION

When salivary calculi are found in a duct or gland they should be removed, not only for the relief of pain, but also to prevent further pathologic changes from developing. As pointed out by Waring,⁷ surgical intervention as a rule is uncomplicated, but a deep seated cellulitis of the cervical tissues has been known to follow the simple removal of a calculus.

OPERATIVE TECHNIC

Most surgeons believe that the stone should be removed by an intra-oral incision if it is situated in the sublingual gland or duct, the anterior two thirds of the submaxillary duct, or the buccal portion of the parotid gland. Total extirpation of the sublingual or submaxillary gland is indicated if a stone is present in the substance of the gland or if there is inflammation of the gland, even though the stone is in the duct. It is not advisable to extirpate the parotid gland.

Calculi usually can be removed under local infiltration anesthesia. Blocking the lingual nerve, as in the mandibular injection for extraction of teeth, also gives excellent anesthesia.

A calculus may be seen impacted in or presenting itself at the orifice of the duct. Simple extraction with

a forceps usually is adequate in such instances. If the stone is farther back in the duct, the duct may be fixed with tissue forceps or a suture, the duct incised parallel with the long axis, and the calculus removed with a scoop or forceps. If the stone has not previously been fastened, it may slip along the canal and enter the hilus of the gland. In nonsuppurative cases, the mucous membranes can be closed without drainage. If an acute inflammatory process or suppuration exists, a small strip of gauze packing or Penrose drain should be left in the incision. Since there may be considerable reaction following the operative procedures lasting for several days, frequent intra-oral irrigations, accompanied by the external application of ice, should be carried out. Drugs of various kinds may be indicated to control pain.

In cases of long standing in which multiple stones are present or when there is chronic inflammation, radical extirpation of the gland should be done. Bailey⁸ says that if symptoms recur after the removal of a stone from Wharton's duct, the gland should be removed in every case. He has found that recurrent calculus often signifies that there are still other calculi within the gland. He also believes that there is a definite relationship between Ludwig's angina and acute inflammation of the submaxillary gland.

Radical extirpation of the gland is carried out as follows. The incision is made parallel to the lower border of the mandible, which is preferable to that used in the classic operation for ligation of the lingual artery, because the main vessels are encountered more easily and without forcible traction on the skin. The platysma myoides muscle is divided along the same line and turned up as a separate layer. The facial artery and vein are identified and divided between ligatures during the dissection of the gland. The inframandibular branch of the facial nerve should be preserved if possible. Its injury will cause drooping of the corner of the mouth, owing to paralysis of the triangularis menti muscle. Although improvement may occur in time, care during the surgical steps must be observed. The accident is difficult to avoid, but there is less chance of its occurrence if the incision is made well below the border of the jaw.

REPORT OF CASE

A white woman, aged 56 when first seen had a marked tender swelling involving the left sublingual salivary gland. The swelling pushed the tongue well over to the right side of the mouth. The patient gave a history of having had many similar attacks during the previous forty years. They always subsided spontaneously but none had been as severe as this one. The attacks usually began when she was eating a meal. The submaxillary duct had been probed several times by her dentist, but without relief or diagnosis. During the past forty years she always was aware of a foul taste in the mouth, especially on arising in the morning.

A diagnosis of left sublingual salivary calculus seemed most likely. The patient was in immediate distress and roentgenograms were postponed. She was advised to irrigate her mouth frequently with an antiseptic mouth wash and to apply continuous external hot fomentations over the swollen tissues.

When seen twenty-four hours later a stone was presenting itself through the orifice of the left submaxillary salivary duct. It was easily extracted with forceps. Palpation revealed further stones and two more were milked down the duct and extracted. When fitted together they measured 3 cm in length by 1 cm in maximum diameter. They weighed 0.5 Gm. The pieces were faceted or articulated together, apparently

having been broken off from one large duct stone, or over a period of years of rubbing together, three separate stones had gradually fitted themselves end to end.

Following the extraction of the calculi, the swelling and pain rapidly abated and has not recurred since (one year). Moreover, the foul taste has been absent. Roentgenograms failed to reveal any further calculi.

GAS BACILLUS INFECTION OF ABDOMINAL WALL

REPORT OF THREE CASES COMPLICATING ENTEROSTOMY

THOMAS G. ORR, M.D.

KANSAS CITY, KAN.

Considering the great number of operations done for intra-abdominal infections, gas bacillus infection of the abdominal wall, as a complication, is quite rare.

In 1925, Ochsner and Schmidt¹ reported a case of gas bacillus infection of the abdominal wall following the drainage of an appendix abscess and removal of a gangrenous appendix. Butler² has recorded two infections of the abdominal wall, one following the removal of a perforated gangrenous appendix and the other following cecostomy. Shearer's³ case of gas infection of the abdominal wall followed the removal of a nonruptured gangrenous appendix. King⁴ describes a case following appendectomy, in which he stated that the smear showed a suggestion of *Bacillus welchii*. Extensive gas infections, following drainage of appendix abscesses, are recorded by Lamprecht,⁵ Traver,⁶ Douglas⁷ and Miyamoto.⁸ Butler and Rhodes⁹ report two cases in which an extensive infection of the abdominal wall by the gas bacillus followed enterostomy for intestinal obstruction. Seven cases of infection of the abdominal wall with gas bacillus, following abdominal operation, are recorded by Eckhoff,¹⁰ one of which followed enterostomy.

REPORT OF CASES

The following three cases are briefly noted as examples of gas bacillus infection of the abdominal wall, as a complication of enterostomy for intestinal obstruction.

CASE 1—A. W., a man aged 44, was admitted to the University of Kansas Hospital, March 29, 1932 and died April 6. There was a history of a rather atypical appendicitis with the development of an abscess in the right lower part of the abdomen complicated by an obstruction of the small intestine. An operation was done the day following admission to the hospital through a right rectus incision. A large appendiceal

abscess was found and drained. An enterostomy was done at the same time in the lower part of the ileum by the Witzel technique. Aerobic cultures made of the pus from the appendix abscess showed *Staphylococcus aureus* and a gram-positive bacillus. Two days following the operation the patient's temperature rose to 104 F and he was irrational. Free drainage from the enterostomy tube and profuse drainage from the incision were noted. On the fifth day following operation, gas was noted in the subcutaneous tissues of the abdominal wall and in the wound. The wound showed a dark gray sloughing surface with a very foul odor. This suggested a gas bacillus infection. The cultures taken of the pus from the appendix abscess the day of the operation were then recultivated by an anaerobic method, and a gram-positive bacillus, producing gas was found. An intravenous injection was made into a rabbit. The rabbit was killed five minutes later and left in an incubator for twenty-four hours. Extensive emphysema was found in the subcutaneous tissues and liver. Large numbers of gram-positive bacilli were present in the liver and recovered in anaerobic culture. This gram-positive bacillus morphologically and culturally resembled *Bacillus welchii*. An autopsy showed general peritonitis due to the ruptured appendix with necrosis of the skin about the abdominal incision.

CASE 2—P. R. S., a man, aged 67, was admitted to the hospital, Nov. 28, 1933, and died, November 30.

There was a history of an old right femoral hernia. The onset of the present illness occurred four days before admission with abdominal pain and persistent vomiting. Examination revealed a strangulated femoral hernia. Study of the chemistry of the blood showed a high nonprotein nitrogen and a low chloride content. Operation was done the day of admission under local anesthesia. The bowel was in good condition and the hernia was reduced. Because of the marked distention and long duration of the hernia, a Witzel enterostomy was done through a small right rectus incision, the first loop of intestine presenting in this locality being used. Following operation the next day the patient had a temperature of 102 F but appeared to be doing fairly well. The evening of the second day he grew very delirious. At the end of forty hours discoloration and subcutaneous gas was noted in the abdominal wall, extending upward from the incision. This increased until it reached the axilla. Blisters formed in this area and the skin turned very dark, suggesting beginning gangrene. He died fifty hours following the operation. Cultures from the enterostomy wound showed a gram-positive, gas-producing organism resembling *Bacillus welchii*. A rabbit was injected and incubated. Smears and cultures from the rabbit showed an organism typical of *Bacillus welchii*. The autopsy showed an acute emphysematous cellulitis of the skin and subcutaneous tissue of the right side of the abdomen and thorax. A localized peritonitis with beginning gangrene of the intestinal loop was noted. The hernia wound was free from infection.

CASE 3—J. B., a man aged 62 was admitted to the hospital, March 15, 1932, and died March 28.

There was a definite history and manifestations of acute intestinal obstruction of six days' duration. Because of his general poor condition a Witzel enterostomy was done with local anesthesia through a left rectus incision. The omentum was interposed between the enterostomy and the abdominal wall. Distention of the small intestine was found, but the cause of the obstruction was not discovered. Five days after the enterostomy, marked drainage was noted from the abdominal wound, evidently a leakage from the intestine at the site of the enterostomy. The scrotum was edematous and his general condition was critical. Seven days following the operation, gangrene of the scrotum was noted with crepitation in the subcutaneous tissue, extending from the suprapubic region up to the enterostomy wound. Death occurred eleven days following enterostomy. General peritonitis was found at autopsy as a result of perforation at the site of the obstruction of the lower part of the ileum, and acute gangrenous cellulitis of the scrotum and abdominal wall. Cultures from the scrotum showed nonhemolytic streptococci and a short, plump, gram-positive bacillus. Anaerobic cultures made later showed a gas-producing organism of the *Bacillus welchii* type.

COMMENT

In the three cases cited, each presented a pathologic condition that might have caused death even though the gas infection had not been present. However, it seems very probable that the gas infection at least contributed to and hastened the lethal outcome. In case 2 the infection evidently developed directly from the enterostomy wound in the ileum. In each instance, the gas-producing organism probably came directly from the intestinal tract.

In considering the diagnosis of gas infection of the abdominal wall it must be remembered that quite an extensive emphysema may develop following closure of an abdominal wound owing to the escape of retained air through the wound into the subcutaneous tissues. This observation was especially emphasized by Russell¹¹ in 1897. A beginning gas bacillus infection is likely to be associated with severe pain at the site of the wound, commencing from twelve to forty-eight hours after an operation. This may be considered one of the early warning symptoms of the onset of this type of infection. Other well known signs and symptoms, such as swelling, skin discoloration, crepitation, foul odor, and the finding of the typical bacillus, develop rapidly, necessitating hourly observations of any suspected wound.

It is quite reasonable to expect gas infections secondary to abdominal infections, since gas-forming organisms are more or less constantly found in the intestine. Jennings¹² found a positive culture of *Bacillus welchii* in 90 per cent of appendices removed at operation. Williams¹³ has expressed the belief that the toxemia of intestinal obstruction and peritonitis is due in part at least to the absorption of the toxin of *Bacillus welchii* but such an assertion still lacks proof.

Since the gas bacillus is present in the small bowel and appendix in quite a high percentage of individuals, the use of antitoxin is quite logical in patients having operations that expose the tissues of the abdominal wall to infection from bowel content.

SUMMARY

Eighteen cases of gas bacillus infection of the abdominal wall following abdominal operations have been found recorded. To this number the three cases here briefly described are added. The diagnosis was not proved by culture in all cases, which made an error in diagnosis possible.

The mortality in the twenty-one cases has been 61 plus per cent.

Because of the possibility of gas infection of the abdominal wall following gangrene or abscess of the appendix, or any operation that involves opening the intestine, clinicians should be on the alert for this complication.

Any unusually severe pain developing in a postoperative wound within twelve to forty-eight hours should suggest the possibility of gas bacillus infection.

In the present state of knowledge, gas bacillus antitoxin seems to be of value in the treatment of gas bacillus infection and is recommended in such infections of the abdominal wall.

OBSERVATIONS ON THE RELATIONSHIP
OF THE VIRUS OF HUMAN INFLU-
ENZA AND DOG DISTEMPER

PRELIMINARY REPORT

ADOLPH EICHHORN, DVM

AND

NORMAN J PYLE, VMD

PEARL RIVER, N Y

Investigations that have been carried out during recent years have revealed that certain diseases of previously obscure etiology are caused by viruses—infectious agents so small that they are capable of passing through filters that hold back all known bacteria.

The list of these viruses is still increasing, and one of the latest additions has been described by Smith, Andrewes and Laidlaw¹ in a study of throat washings from influenza patients. These investigators inoculated ferrets intranasally with the bacteria-free filtrates from the throat washings and regularly observed the occurrence of a febrile condition in these animals, indicating an infectious process.

The ferret disease is characterized by a two-day incubation period, a diphasic temperature response and symptoms of nasal, catarrhal and systemic disturbances. The temperature rises often above 106 F, it subsides on the third and fourth day but rises again on the fourth and fifth day, after which it gradually returns to normal. Systemic symptoms are lethargy, inappetence and muscular weakness. The eyes and nose show a watery discharge. The symptoms usually subside within from six to ten days, after which the ferret becomes perfectly normal. According to Smith, Andrewes and Laidlaw, the disease has never been fatal in ferrets in the sixty-four cases that they observed throughout the full course of illness. This experience has been confirmed by us in our experimental work with this virus.

The postmortem changes as observed by us coincide with those described by the original investigators and are as follows. In ferrets killed during the first and second febrile periods the mucous membrane of the nasal passages shows acute inflammation. Sections across the turbinate bones show, in the soft parts, acute vascular congestion, dilated lymph channels, numerous leukocytes passing out through the epithelium, and serious derangement of this structure. There is almost invariably complete disappearance of ciliated cells, and occasionally patchy necrosis of the whole thickness of the epithelium may be observed. No histologic feature, such as an inclusion body, has as yet been discovered that can be called characteristic of the disease.

For propagation of the virus, the English investigators employed the following technic. Throat washings from eight human cases diagnosed as influenza were inoculated into ferrets. Five of these produced the disease in ferrets. Six days following the onset of the disease in man no virus was recoverable from the nasal discharges. The filtrate, prepared from an emulsion of the lung tissue from a fatal case of influenzal pneumonia likewise produced the ferret disease. Throat washings from human subjects not suffering from influenza were noninfective.

From the Lederle Laboratories, Inc.

1 Smith, Wilson, Andrewes C H and Laidlaw P P. *Lancet* 2: 66 (July 8) 1933.

Carefully checked experiments confirmed the filtrability of the virus. According to Smith, Andrewes and Laidlaw, ferrets recovered from the disease were immune to subsequent infection with the same strain of virus. In our own experiments, we found that only a percentage of such ferrets showed definite immunity. Others reacted to the second injection of the influenza virus with a rise in temperature.

EXPERIMENTAL DATA

During a visit to England in July 1933 the senior author secured a small amount of the dried virus for the purpose of testing the susceptibility of pigs in the United States to the influenza virus of man. The virulence of the virus was maintained through passage in ferrets and, in the course of this work, the virus, for some reason or other, lost its infectivity for ferrets. A fresh supply was obtained from Smith, Andrewes and Laidlaw, which, on arrival in our laboratory, proved infective for ferrets. This virus has been kept active through passage in ferrets for thirty generations.

The virus was propagated by instilling the virus into the nasal passages of the ferrets, two ferrets were used

a uniform incubation period as previously mentioned, these results, even in the limited number of suitable animals at our disposal, clearly suggest that the animals which had recovered from the infection with influenza virus had acquired a resistance to the canine distemper virus. This resistance could not be due to local changes in the nasal mucous membrane caused by the influenza virus because the subsequent tests with the distemper virus were made by injection.

These interesting changes suggested a repetition of the experiments. A second series of eleven ferrets were given two and three nasal instillations of influenza virus and then were subjected to an injection of canine distemper virus in amounts that always proved fatal to susceptible animals. The results are tabulated in the accompanying table.

Of the eleven ferrets, six received only two instillations of the influenza virus, of which only one remained well. Of the five remaining ferrets which received three nasal instillations, three remained well. All ferrets that died showed a marked delay of the distemper symptoms, which is apparent when compared with the three control animals.

† Not distemper.

for this purpose. At the height of the reaction, one ferret was destroyed and the virus removed and preserved in the described manner. In due time, a large number of ferrets recovered from the influenza virus were accumulated.

It is our routine practice to employ ferrets in the testing of canine distemper virus and, not suspecting a possible relationship between this virus and that of influenza, we used some of the ferrets that had recovered from the influenza infection for tests with canine distemper virus. However, it was observed that these ferrets did not react to the virus of distemper in the same manner as they usually do to such virus injection. There was a very pronounced delay of the period of incubation and, in view of this peculiarity, it was deemed advisable to subject all the remaining ferrets to an injection with the distemper virus, eleven ferrets in all having been used. The results showed that the usual period of incubation of from nine to ten days following the injection of distemper virus was extended to from thirteen to seventeen days, and two of the ferrets proved apparently immune to distemper.

In view of our experience that the strain of distemper virus, with which these experiments were made and which has been studied in more than 800 ferrets, never has failed to kill these animals and always shows

It is apparent from these experiments that the influenza virus induces some immunologic reaction in ferrets against the distemper virus. Limited cross-neutralization experiments and immunizing attempts with hyperimmune distemper serum against the influenza virus are now in progress and will be reported on at a later date.

From time to time, claims have been made of the close relationship of influenza in man and canine distemper in dog. However, no definite proof has been presented of the identity or the relationship of these viruses. The data submitted strongly point to the possibility of such a relationship and it is hoped that the experiments now in progress will further clarify knowledge with regard to these viruses.

CONCLUSIONS

The virus of influenza in man apparently induces an immunity in ferrets against the distemper virus of dogs.

The available experimental data, as indicated in this preliminary report, suggest a possible relationship of influenza in man and distemper in dogs.

Experiments are now in progress to determine the possibility of cross-immunization with the virus of influenza and the virus of distemper in dogs.

EFFECTS OF INTRAVENOUS ADMINISTRATION OF HYPERTONIC SOLUTIONS OF DEXTROSE

WITH SPECIAL REFERENCE TO THE CEREBROSPINAL FLUID PRESSURE

JULES H. MASSERMAN, MD

Resident in Neuropsychiatry Baltimore City Hospitals
BALTIMORE

Following the discovery that the introduction of concentrated solutions of various salts or of dextrose into the blood stream¹ or the gastro-intestinal tract² of an experimental animal causes a diminution in its cerebrospinal fluid pressure, hypertonic solutions have been administered clinically by different routes in attempts to reduce intracranial hypertension in patients suffering from brain trauma,³ brain tumor,⁴ meningitis⁵ or brain edema with acute infections⁶. However, more recent observations both in animals⁷ and in a small number of human beings⁸ have indicated that the initial decrease in the tension of the cerebrospinal fluid induced by these methods is superseded within from one to three hours by a persistent rise in subarachnoid pressure and an exacerbation of the initial symptoms of intracranial hypertension.

The problem, therefore, appeared to require further investigation. It is my purpose in this paper to report a study of certain clinical and rachimydodynamic effects of the intravenous administration of solutions of dextrose in various amounts and concentrations to eighty-five human subjects under controlled experimental conditions.

METHOD

Patients between 20 and 40 years of age and free of clinically determinable organic disease were chosen for this study. Ten grains (0.6 Gm.) of barbitol was administered to each patient to promote relaxation. He was then allowed to rest in the right lateral position for half an hour, after which his pulse rate and blood pressure were determined. Lumbar puncture

was then done under local anesthesia, and a glass manometer filled to the 150 mm mark with sterile Ringer's solution was connected to the spinal needle with the loss of as little fluid as possible. When a satisfactory control reading of the patient's "basic" cerebrospinal fluid pressure⁹ during from fifteen to sixty minutes had been obtained, solutions of dextrose in various amounts and concentrations were injected intravenously at the rate of from 10 to 20 cc per minute, dextrose being chosen for use in this study because, in contrast to various electrolytic salts, it is apparently nontoxic when given intravenously in concentrated solution¹⁰. During the injection and for a period of from two to six hours thereafter, the patient's spinal fluid pressure was read at least every ten minutes, in addition, his pulse rate, blood pressure and general condition were recorded half-hourly during the experiment and also at various intervals during the ensuing forty-eight hours. In twenty-four cases, moreover, lumbar and/or cisternal punctures were performed eight, twelve or twenty-four hours after the administration of the dextrose in order to determine the general course of the cerebrospinal fluid pressure subsequent to the period of continuous observation¹¹.

EFFECTS OF THE INTRAVENOUS ADMINISTRATION OF HYPERTONIC SOLUTIONS OF DEXTROSE

Clinical.—The administration of less than 55 Gm of pharmacologically pure dextrose in simple 20 to 50 per cent solution produced no adverse symptoms in our subjects,¹² when, however, more than 100 Gm of dextrose in greater than 20 per cent concentration was given intravenously to thirty-two patients, twenty-three of them subsequently complained of headaches, backaches or peripheral nerve pains, which began from one-quarter to one hour after the injection of the dextrose and persisted during the ensuing three to thirty hours. Concentrations of dextrose of from 35 to 50 per cent produced pain in the injected vein in about 35 per cent of cases, but none of our patients developed an overt phlebitis. Of the twenty-four patients who received 185 Gm or more of dextrose, fourteen subsequently showed elevations of temperature reaching 100 to 102.8 F in from three to five hours, with subsidence to normal in from three to eleven hours. Since eight of the sixty-one patients who received 100 Gm of dextrose or less also had some degree of pyrexia, the possibility of pyrogenic impurities¹³ in some of the dextrose preparations cannot be altogether excluded.

Contrary to previous comparable observations,¹⁴ no constant rise in systemic arterial blood pressure after

the injection of hypertonic solutions was observed, nor was there any significant effect on the pulse rate

Effects on the Cerebrospinal Fluid Pressure—The average deviations of the cerebrospinal fluid pressure following the intravenous injection of various amounts and concentrations of dextrose are plotted in the accompanying chart. To summarize the data: 1 The administration of 10 per cent dextrose intravenously to sixteen patients produced an increase in cerebrospinal fluid pressure whose duration and height were in direct proportion respectively to the amount of solution administered and to the speed with which it was injected, no consistent secondary deviations in the cerebrospinal fluid pressure were observed with the isotonic preparations.¹⁷ 2 Similar but somewhat smaller initial rises in cerebrospinal fluid pressure were produced by the injection of the hypertonic solutions. 3 When more than 75 Gm of dextrose was administered in from 20 to 50 per cent solution, this initial effect was followed by a fall in cerebrospinal fluid pressure of from 26 to 162 mm of water, the curve of pressure reaching its nadir at from 50 to 170 minutes after the injection. 4 In the ensuing 50 to 120 minutes, the cerebrospinal fluid pressure then recovered to the basic level, after which (5) the upward trend continued until levels of cerebrospinal fluid tension of from 8 to 148 mm above normal were reached and, in most cases, maintained throughout the remainder of the period of continuous observation.

In the twenty-four cases in which puncture was done at from eight to twenty-four hours after the injection of dextrose, the mean of the cerebrospinal fluid pressure readings, taking into consideration the range of normal variability of the basic cerebrospinal fluid pressure,⁹ did not differ significantly from the mean of the initial spinal pressures of the same patients before the injection of dextrose. It appears, therefore, that in the majority of cases the reactive intracranial hypertension had subsided within eight hours after the administration of the dextrose.

COMMENT

The initial rise of cerebrospinal fluid pressure during the intravenous administration of the dextrose solutions is apparently an expression of the concomitant increase in cerebral venous tension produced by the rapid injection of fluids into the circulation¹⁰ and probably has no other immediate significance. On the other hand, the ensuing diminution in subarachnoid pressure in cases in which the dextrose had been administered in effective concentration¹⁷ is of greater physiologic importance and may be attributed both to a resorption of the spinal fluid¹⁸ and to a diminution in the volume of the nervous

tissue itself.¹⁰ Conversely, the rise of cerebrospinal fluid pressure to normal and above subsequent to the period of depression would then theoretically be due to (1) an increased rate of dialysis of cerebrospinal fluid from the blood, which had meanwhile been rendered relatively hypotonic to the cerebrospinal fluid through the loss of dextrose and salts in the urine, and (2) the deposition of dextrose in the nervous tissues with ensuing compensatory intercellular and intracellular edema.²⁰ The possibility of the latter two effects is of prime clinical importance, since they may well account for the recurrence and exacerbation of symptoms of increased intracranial pressure after a

Mean deviations in the pressure of the cerebrospinal fluid in sixty nine human subjects following the intravenous injection of hypertonic solutions of dextrose at rates ranging from 10 cc per minute for 100 cc to 20 cc per minute for 1,000 cc of the solution. Although the data in each series are not sufficiently numerous to justify explicit statistical derivation the respective curves nevertheless represent deviations in cerebrospinal fluid pressure of such relative constancy as to render the experimental results clinically significant.

transient initial improvement in patients suffering from intracranial hypertension treated by the intravenous administration of various types of hypertonic solutions.²¹

SUMMARY

The effects of the intravenous injection of solutions of dextrose in various amounts and concentrations were studied in eighty-five normal patients. The administration of 50 Gm or less in 20 per cent solution produced no untoward clinical sequelae other than diuresis, however, the intravenous injection of 100 Gm or more in 35 to 50 per cent solution caused headaches and other adverse symptoms in 72 per cent of cases, whereas 58 per cent of the patients receiving 185 Gm or more suffered transient pyrexia. The intravenous administration of isotonic solutions caused a transient increase in cerebrospinal fluid pressure, with hypertonic solutions in effective concentration (100 to 200 Gm in 20 to 35 per cent solution) this initial rise was followed by a secondary fall in cerebrospinal fluid pres-

15 To simplify the chart the curves plotted from these data are omitted as are the designations of the numerous coordinative points to which the average curves for the hypertonic solutions were approximated.

Spinal Fluid Pressure in Relation to the Bony Encasement of the Central Nervous System as a Rigid Container, *Am J Physiol* 58:85 (Nov) 1921, Intracranial Venous Pressure and Spinal Fluid Pressure as Affected by Intravenous Injection of Solutions of Various Concentrations, *ibid* 58:101 (Nov) 1921.

17 This diminution in cerebrospinal fluid pressure seems of potential therapeutic value in cases in which it is imperative to break the vicious cycle of a rapidly progressive intracranial hypertension and resultant cerebral ischemia. However, such decompression as is possible in this way may in suitable cases be accomplished through slow, repeated spinal drainages (Jackson¹⁴, Masserman¹⁵) without the risks apparently attendant on the intravenous use of strongly hypertonic solutions.

THE STUDENT NURSE AND TUBERCULOSIS

J ARTHUR MYERS, MD

HAROLD S DIEHL, MD

MINNEAPOLIS

AND

H D LEES, MD

PHILADELPHIA

Tuberculosis among nurses has long been a serious problem, although it has not been generally recognized in this country. As the morbidity and mortality from tuberculosis in the general population have decreased, the incidence of disease among nurses has become more conspicuous and the magnitude of the problem more obvious. The problem is of universal interest among physicians, since some of them send their daughters to schools of nursing, many of them teach in such schools and nearly all of them recommend nurses to their private patients.

A small group of physicians from various parts of the world has brought to light the fact that in some hospitals outrageously high percentages of students of nursing became contaminated with tubercle bacilli. It is almost unbelievable that with so much available knowledge of techniques which are effective in preventing the spread of disease, a hundred per cent of the girls who entered the school of nursing of the Ulleval Hospital in Oslo and the Ancker Hospital in St. Paul without infection from tubercle bacilli should become so infected before graduation. In view of this, it seems logical to conclude that many who were already infected on admission to the schools probably were reinfected before graduation.

In an attempt to determine how serious was the offense being committed by various types of nursing schools, we tested with tuberculin the junior and senior students in two schools of nursing in 1929. The results are seen in chart 1. School 1 has a tuberculosis service of approximately thirty beds, where the students at that time gave intimate care to patients with no protection of any avail. School 3 has no tuberculosis service as such but admits tuberculous patients. In school 3 it is possible for girls to complete their course without being assigned to a tuberculous patient. Obviously, the more exposure the more contamination with tubercle bacilli, as seen in chart 1.

Although the contamination in school 3 was a good deal less than in school 1, it was still too high since we knew that among the girls entering a university in the same city the incidence of positive tuberculin reactors was only from 30 to 35 per cent. In order to prove definitely whether most of the contamination occurred during the course of training we subsequently observed the nurses of two classes with reference to tuberculin reactions from the time they entered until they graduated. To schools 1 and 3 we added school 2

which admits tuberculous patients but does not have a tuberculosis service and a school of education.

In chart 2, one sees that slightly less than 40 per cent of the probationers who entered school 1 (with a tuberculosis service) in 1929 reacted positively to the test, but in the senior year all had become positive to the tuberculin test. In school 2, less than 25 per cent of the probationers reacted positively, while in this same class only slightly more than 25 per cent were positive in the senior year. In school 3, slightly more than 25 per cent of the probationers were positive but when the senior year was reached slightly more than 45 per cent of the class was positive. In chart 2, the percentages of positive reactors among the probationers and again in the senior years of the three schools of the class entering in 1930 are recorded. In chart 2 one also sees the percentage of positive reactors among the freshmen of the School of Education in the University of Minnesota in 1929. By the time this class had reached the senior year the positive reactions had increased only 4 per cent. One must bear in mind that these students spend one more year in school than those of the schools of nursing. From this figure it is obvious that school 1 with a tuberculosis service is transmitting tubercle bacilli to large numbers of its student nurses, whereas schools 2 and 3 are transmitting bacilli to some of their students but to a much smaller number than school 1. In fact, in the class entering school 2 in 1929 there is approximately the same increase in positive reactors by the time they had reached the senior year as in the school of education. The detailed results of this study will be reported later.

The contamination of girls who entered free from tuberculous infection was determined by the tuberculin reaction. A positive reaction indicates the presence of at least one focus of tuberculosis somewhere in the body which has rendered the tissues allergic. Certainly one would not look on a focus of living and virulent

Chart 1.—Tuberculin reaction in student nurses. School 1 with tuberculosis service, school 3 without service.

tubercle bacilli, even when encapsulated, as an asset to the body, any more than one would look on allergy as an asset. Therefore, the hospitals that have infected for the first time or reinfected their students have committed a serious offense against them. A good many of these girls will suffer from clinical tuberculosis as the decades pass, and some of them will die from that disease. In fact, more than 11 per cent of the students entering school 1 negative to tuberculin in 1929 are already suffering from clinical disease. From this, one must not gain the impression that those who enter schools of nursing already positive to the tuberculin test are by any means safe. For example, of one class of six students who entered school 2 in 1932, only one reacted positively on admission. Roentgenograms of this girl's chest were clear. However by the end of the first year she had pulmonary tuberculosis with cavity formation.

We have had an opportunity to study rather carefully the sequence of tuberculosis events in the bodies of students of nursing and medicine who reacted negatively to the test on entrance to school but who became positive before graduation. Not one became positive to this test because of overwork, bad housing conditions, improper food and the like. There is always a definite exposure as the first event.

Following exposure there is usually a period of approximately three weeks during which there is no test or phase of examination to determine that the body has become contaminated. After about three weeks, the second event is the presence of sensitiveness of the tissues to tuberculin, as demonstrated by positive reaction to the tuberculin test.

From this it is known that at least one focus of tuberculosis is present. In many cases it is never possible to locate the focus by any phase of examination during life but in a small percentage, after a period of approximately from three to five months, following the development of the positive tuberculin reaction, the focus has become sufficiently large to cast a shadow on the x-ray film.

There may be no other event, in fact, in 80 or 90 per cent of contaminated individuals no other clinical changes are ever observed. However, this is only an estimate, since no one has yet traced a large group of infected individuals from the early adult period through the span of life. Nevertheless, it would seem to be a very conservative estimate based on brief periods of time during which such cases have been followed. When other events do occur they are due to the reinfection type of tuberculosis, which may be from endogenous or exogenous sources. The first clinical event may be miliary tuberculosis or tuberculous meningitis, again it may be pleurisy with effusion, pulmonary disease, tuberculosis of the bones and joints and the like, or a combination of these.

It is disappointing to see that some of the hospitals which should be true health centers and which should be putting into practice the very best that is known concerning the prevention of disease, are in reality hotbeds for the propagation and dissemination of tubercle bacilli to student nurses.

When one calls attention to the high incidence of positive tuberculin reactors among seniors or recent graduates of schools of nursing and the low incidence among entering students to many of these schools, the question is often asked as to whether these positive reactions have not been brought about through the ingestion of dead bacilli. Another question rather recently asked is whether this is not a manifestation of a general allergic phenomenon that has no particular significance. One should not be misled nor treat a serious problem lightly, for it is known that tubercle formation is present or is taking place when a human body reacts positively to the tuberculin test.

To allow a human body to become contaminated with tubercle bacilli is to set a potential stage for every scene of destruction of which the tubercle bacillus is capable. Many other pathogenic micro-organisms that contaminate the human body are soon destroyed by the protective mechanism, but not so with the tubercle bacillus. When bacilli first enter the body some of them become encapsulated, where they live year after year, ever retaining their virulence and ever ready to destroy, once they escape from their capsule. Moreover, as they pass through the stage of primary encapsulation they sensitize the body tissues so that other

bacilli that may come into the body subsequently are not so easily encapsulated and thus often cause much destruction of tissues and organs.

Thus, he who ponders long and carefully over this subject will not congratulate a parent whose infant has recently become contaminated with tubercle bacilli but is not ill. Nor will he congratulate students of nursing and medicine who appear well but who have recently become contaminated with tubercle bacilli, on the ground that they have received the proper dose to protect them.

If any physicians or any nurses who graduated five or ten years ago are not convinced of the great destruction of tuberculosis among the members of their professions, let them attempt to get in touch with their first-year classmates, most of them will be convinced.

Chart 2—Tuberculin reaction in student nurses and in college of education students. School 1 with tuberculosis service schools 2 and 3 without tuberculosis service.

of the seriousness of the problem by finding that a surprisingly high percentage have been ill or have died from tuberculosis. In this country a good many physicians and nurses are engaged in sanatorium work and a good many in other phases of tuberculosis and chest disease activities in private practice. In conversing with such physicians and nurses one is amazed at the large number who have had clinical manifestations of tuberculosis and of this group the number in whom such manifestations developed either in school or soon after graduation.

The medical profession has a great responsibility in changing the situation. If it does not act, the courts will solve the problem. Already tuberculosis contracted in line of duty in a hospital has become a compensable disease. The Industrial Commission of the State of Wisconsin has drawn awards in favor of professional workers in whom tuberculosis developed while they were working with tuberculous patients.

Medical men know how to solve this problem and should not allow discredit to come to the profession and hospitals through intervention of the courts. Moreover, the future of the school of nursing is in jeopardy whenever parents become sufficiently informed as to the contamination that threatens their daughters when they enter schools of nursing. Intelligent and informed parents, who for fifteen or twenty years have given meticulous care to the rearing of a daughter, whose

success and welfare have become the pride of their lives, are not likely to allow her to enter a school of nursing without reasonable assurance that every possible effort will be put forth to keep her body free from contamination with tubercle bacilli and every other communicable disease.

Every hospital has the problem of patients with tuberculosis being admitted for some other condition, such as one requiring emergency surgery. Unless a special examination is made, the patient remains in the hospital until he has recovered from the urgent condition without the staff of physicians and nurses knowing of the presence of tuberculosis. This problem is very easily and cheaply solved by making an x-ray film of the chest of every patient admitted to the hospital. Most of these institutions already have their x-ray equipment and staff of technicians employed. Usually they are not working to capacity. Films of the chest of new patients would not tax their capacity. With paper films, which are entirely satisfactory for chest work, the total cost of making a film of the chest should not exceed 40 cents. When a patient is found to have tuberculosis, he should be admitted as previously, but adequate protection should be provided all who come in contact with him.

Some hospitals have an additional problem of a special tuberculosis service or an affiliation with a sanatorium for the tuberculous. We do not think that these should be discontinued, for they are very essential in the tuberculosis program and in the proper training of nurses and physicians. However, in these services and in the sanatoriums where students are taught, strict contagious technic, such as that employed in a diphtheria service, is essential. Nothing short of this will solve the problem, since it has been demonstrated that with modified contagious technic approximately as many student nurses become contaminated with tubercle bacilli as when no technic is used.

It is generally believed that 100 years ago nearly all young adults had been contaminated with tubercle bacilli. At that time the mortality in this country was approximately 450 per year for 100,000 population. It would seem logical to conclude, therefore, that if 100 per cent of the student nurses were contaminated there would be among them a mortality similar to that of the general population of 100 years ago. Thus, while tuberculosis in the general population has very materially decreased in the nursing profession the stage is constantly being set for the high mortality of 100 years ago.

Not long ago there was prevalent a fatalistic view which often led to the statement that nurses or physicians could not remain free from contamination with tubercle bacilli because they came in contact with tuberculous patients so frequently. Conditions have changed so much that this view is no longer justified. Marked reduction in clinical cases of tuberculosis together with the realization of its communicability, as well as actual observation, has shown that many students may go through nursing schools without becoming contaminated. If they are properly trained with regard to tuberculosis, many of them should be able to go through life without contamination.

If conditions are considered as they existed fifteen and twenty years ago, when most of the present students of nursing were infants or small children, and contrasted with present conditions, it will be readily seen that the infant of today has a much better chance of growing to adult life without contamination than

infants of that time. Therefore, it would be expected that the incidence of positive tuberculin reactors among probationers in schools of nursing would continue to decrease until the positive reactor on entrance to a school of nursing would be the exception. Already whole classes of probationers have been tested without a positive reactor being found.

Where there is no infection with tubercle bacilli, there are no tuberculous potentialities and thus no tuberculosis problem. In the schools that we have observed, there is already a tuberculosis problem among the probationers when they enter, since from approximately 15 to 40 per cent are already infected. The problem is to keep them under close observation for the development of clinical disease and treat it as early as it can be located. Unfortunately, some schools materially increase their problem by allowing the uninfected students to become contaminated. For example, among the probationers entering school 1 (chart 2) in 1930, slightly less than 15 per cent had been infected. Here the problem was small, but before the class graduated more than 85 per cent had become contaminated and the problem had been more than quadrupled. Thus, the problem exists. It is serious and can be solved only through the efforts of the medical profession and closely allied workers. Following a long period of observation and with much experience the National Tuberculosis Association has for several years in its slogans and elsewhere emphasized the importance of preventing infection with tubercle bacilli. The tumbling down of the death rate and the markedly reduced morbidity in the general population have become very noticeable. As physicians, we can do no better than to apply the same methods to schools of nursing.

COSMETICS—PAST AND PRESENT

JOHN GODWIN DOWNING, M.D.

BOSTON

Cosmetics and vanity are twins and can be traced by the most ancient historical documents to the earliest records of which burials have been found, from the Egyptian tombs there is evidence that the ancients used eye and face paints, oils, solid fats and perfumes.

The two most common eye paints were malachite (a green ore of copper) and galena (a dark gray ore of lead), the latter ultimately replacing the former as the principal eye paint of the country. These substances were placed in graves in small linen or leather bags in the crude form. The prepared form, called kohl, has been found in shells, in segments of hollow reeds wrapped in leaves of plants, and in small vases.¹ Kohl was found either as a paste (now dried) or as a powder, and analyses by Barthoux² and Lucas³ showed that the material in 64 per cent of the specimens was galena, while the rest included carbonate of lead, black oxide of copper, brown ochre, magnetic oxide of iron, oxide of manganese, malachite and chrysocolla (a greenish blue ore of copper), fifty-eight specimens examined showed only a trace of antimony in three, while a fourth consisted of an antimony compound. Lucas considers it wrong to say that ancient Egyptian kohl always consisted of or contained antimony or an

³ Lucas A. *Ancient Egyptian Materials* pp. 59, 104, 146, 147.

antimony compound, that it is misleading to term it "stibium," an early Latin name. This mistake probably arose from the words "stimm" and "stibi" used by Pliny,⁴ to designate an antimony compound employed by the Romans in eye cosmetics and eye medicines. It is doubtful that any of these substances contained aromatic essences, for the impregnation of these substances would have required a knowledge of distillation, and it is believed that this process was not discovered until the fourth century B. C. when mentioned by Aristotle.⁵

In addition to painting around their eyes, the ancient Egyptian women probably colored their cheeks, for certain red pigments have been found in graves associated with palettes and on stones on which it was ground for use, this pigment was red ocher, occurring naturally as red oxide of iron, and is generally termed "haematite." Egypt has a hot, dry climate, so that the use of oils and fats by the poor and the rich has always been popular—the most popular being castor oil, which grows wild in this country.

The leaves of henna, an Egyptian shrub, were used in ancient Egypt in the form of a paste to color the hands, feet, nails and hair. Elliot Smith⁶ described the hair of the mummy Hontumihou (eighteenth dynasty) as being dyed a brilliant reddish which, he suggests, was done with henna. Various other authors mention the use of henna on the fingernails, others suggest the possibility that these stains on the nails were caused by embalming material.

There is evidence that certain plant perfumes such as resins and gum resins were known by the ancient Egyptians. These plant perfumes were made either by laying the petals of the flowers in solid fat or by soaking them in oil, and when these substances were thoroughly impregnated the petals were removed. Among the early Egyptian perfumes frankincense should be mentioned, and Breasted⁷ states that this can be traced as early as the sixth dynasty. Frankincense is thought to be the white incense mentioned in the papyrus Harris (twentieth dynasty), Myrrh, a fragrant gum resin is mentioned and storax (styrax) a balsam belonging to the natural order Hamamelidace was also known.

The Egyptian baths are a matter of history and these were later copied by the Greeks and subsequently became elaborate in the days of the Romans, when beauty culture reached new heights, then the tall, slim type of young woman was favored. Dieting and binding of the breasts are described by Catullus (Carm. LXXVI), those with too flat a figure used padding.

Superfluous hair in those days was considered unsightly, all well groomed girls were expected to have smooth legs, and they plucked the hair from the face, armpits and other areas of the body. Evidently the depilatories of those days were not any more successful than those of today, for Pliny the Elder states "In using every psilothrum (a depilatory ointment) the hairs must be first plucked out." Psilothra mentioned included the blood cells and liver of sea fish, with leeches and lice occasionally added. Pumice stones were also used for removal of hair, shaving was first brought to Italy in 300 B. C.

Special care was given to the teeth, the ashes of various animal substances being used as dentifrices.

False teeth, made of bone or ivory, were held in place with gold wires. Martial in a satire speaks

Haer you bought, and teeth and rouge and wax to make you pale,

You would have bought an eye as well—there wasn't one for sale

Skin tighteners and wrinkle removers were eagerly sought in those days. Ovid mentions various preparations, including the use of honey and barley to soften the skin and here one first hears of face packs such as egg washes and halcyoneum, which Pliny states consists of the thickening filth of sea foam or some slime or woolly substance of the sea which was used for wrinkles. Poppaea, the wife of the emperor Nero is said to have used a poultice made of a substance like bread dough soaked in ass's milk, which she spread over her face at night and washed off with milk in the morning, followed by a facial massage for which also this milk was used, she took a herd of asses with her wherever she traveled and used their milk for tub baths.⁸

Although hydrous wool fat, an ingredient of most beauty creams, was not brought forth until the latter part of the twentieth century, both the Greek and the Latin writers speak of the famous oesypum, a sort of hydrous wool fat salve made of the grease from sheep's wool, which had a strong disagreeable odor and was used as a softening and cleansing salve.

Toward the end of the second century A. D., Galen, a celebrated Roman physician, wrote a four volume work summarizing the literature of beauty culture to date. Many complicated facial treatments were described by Ovid in his work "Medicamina Faciei Femineae."

Various types of treatments for freckles were used, the use of rouge was widespread, even eyebrows were painted in those days. Xenophon (Oeconomicus X, 2, 5, 7) relates the still popular scene of a young husband telling his wife that instead of using cosmetics she would be much better if she kept her complexion clear and red by exercise from the usual household activities, such as weaving, kneading bread and shaking coverlets. Martial, the famous satirist of the day, in an epigram (IX, 37, 4f) states

The face you show the world is laid at night

Not in your bed, but in your hundred rouge-pots

Rouge was made mostly from vegetable dyes, among them was fucus, a product of a root of a plant, red lead also was used. The use of chalk and white lead (cerussa) intended to whiten the face in a manner comparable to the practice of enameling faces, which prevailed fifty years ago, was not neglected by Martial (1, 72, 5f) in his lines

Blackberry hued Lycoris feels delight

Knowing Cerussa makes a dark face white⁸

Beauty plasters of soft leather were worn not only by women but by men, although sometimes they were used to set off the complexion they also had their value in concealing defects or marks of the branding iron on the foreheads of rich freed men.

There are numerous references to the dyeing of hair, bleaching also was very popular. Ovid mentions the dryness, brittleness and poisoning from hair dyes. Tertullian also speaks of the danger in the use of hair dyes, however, they were more advanced in their

⁸ Wilner, O. L. Roman Beauty Cultures Classical J. 27: 26 (Oct.) 1931

prophylaxis, for Marcellus insists that after the use of his concoction the hair be bound in cloth until dry. The face was always greased before the application of a dye to prevent its being stained by some stray dripping of the dye, and the mouth was kept full of oil until the dye was dry to prevent the teeth from turning black. Vegetable, animal and mineral substances were included in the list of coloring materials. Of the latter, lead was the most popular and was acquired by allowing the most nauseating mixtures to decompose in lead vessels. Another very important dye substance was made from walnuts and acorns, which were gathered when very green and their juice applied with a comb. Wigs were very popular and were sold in the open market. The use of rouge and hair dye is a favorite subject of mythology and among the Romans it was unquestionably very popular, but it was not universal, the principal users being the courtesans and the sporting class.

The various authors from 500 B. C. to the present day make frequent references to the use of cosmetics.

In 1909 there were 429 establishments manufacturing cosmetics, doing a business of \$14,211,969. By 1931 the number of manufacturing establishments had increased to 657 doing a business of \$156,375,744, and the last report was that the wholesale value of the products sold amounted to over \$250,000,000. At the present time there are 41,000 beauty shops and 80,000 barber shops in the United States employing 170,000 women and 250,000 men.⁹ However, the latter figure in no way reveals the number employed in this work, because I investigated last year those in Boston alone. In 1932, 3,018 licenses were issued for beauty work, but it is estimated that despite the energies of the health department half as many again are engaged in this work, having as their place of business a room in their home. Boston has tried to prohibit these residential establishments not only for sanitary but for moral reasons, and now every application is first acted on by the zoning board which passes on it as to whether the location is in a business zone or whether it is residential, if residential, it is disapproved and the applicant is told not to work in that location.

Although women do and will continue to pay ridiculous prices for cosmetics that are of little or no value, still as a result of the efforts of the American Medical Association there is unquestionably an effort on the part of the manufacturers to prevent the selling of harmful substances, and the various associations of cosmetic manufacturers state that they will admit no one to membership who uses paraphenylenediamine in their compounds.

With such a tremendous increase in the cosmetic business there has been an alarming increase in the number of local disturbances of the skin, and some systemic results have also been reported. Fortunately, most of them are not severe. Many women try a new powder or cream and it immediately irritates their skin so they discontinue its use. The physician is consulted only when there is a violent reaction or when the long interval between the time of application of these preparations and the beginning of symptoms makes it impossible for the users to determine the cause of their skin irritation or the loss of previous good health. Every busy dermatologist sees one or more cases a week of some result of cosmetics, but few report these cases. Frequently they are not proved

cases, a cosmetic is suspected, the patient is advised, gets well and refuses any testing to prove the case, and one hesitates to report a case without scientific proof. Out of 437 questionnaires for the investigation of injuries from hair dyes, dyed fur and cosmetics, only sixty-two were returned.¹⁰

Powders rarely contain bacteria, although Kapp¹¹ made a bacteriologic examination of sixty-seven powders from powder boxes taken from his private patients and found various types of bacteria, these were probably contaminations from the powder puffs used. He thought that the vegetable powders injured the skin through the swelling of the powder granules in the cutaneous fat and moisture and considered rice powder the least harmful. Mineral powders irritate because some of the grains have sharp edges and spicules, especially those containing calcium sulphuricum and terra silicea. The least harmful mineral powders are those containing zinc oxide, precipitated magnesium carbonate, and magnesium silicate. Powders also are of two types—heavy and light. The light contain magnesium compounds and occasionally the heavy contain lead acetate, which has been prohibited in Germany. Numerous face powders contain orris root, which is used as a perfume fixative and may not produce a hypersensitiveness until after a long period of use.

Persons using perfumes containing oil of bergamot on unprotected skin should not expose themselves to the sun, for the combination will produce a disfiguring pigmentation.¹²

With the almost universal use of lipstick, irritation of the lips (cheilitis) is rarely encountered, for the natural dyes such as burnt sienna, cantharum and carmine used in them are fairly safe, although Miller and Taussig reported lipstick dermatitis due to the second.

Soaps containing more than 0.25 per cent of free alkali will irritate certain skins.

Pyrogallol and paraphenylenediamine (also known as urso) will irritate one in a hundred skins, and even the lay person is aware of the dangers in their use. No operator should use a hair dye on a person who has had a previous dermatitis from dye.

The various sulphites, calcium, barium, sodium, strontium and magnesium, to remove superfluous hair will frequently cause a dermatitis. The dangers of the use of thallium acetate have been known since Sabouraud pointed out its dangers in the latter part of the last century.

McKenna states that the irritating effects of cold creams is intensified by the successive application of vanishing cream and thinks that the fats block the sebaceous and sweat glands and interfere with the perspiration, causing the temperature of the skin to rise and leading to a continued dilatation of the superficial blood capillaries and eventually to an acne rosacea,¹³ a good cleansing at night will prevent this.

Freckle creams and bleaches generally contain mercury, they may cause an acute dermatitis or pigmentations such as those reported by Goeckerman,¹⁴ Wedd¹⁵ and Woltman,¹⁶ the latter reported a case of lead

poisoning such as that seen after the continued use of face powders and enamels containing lead acetate

Men use hair tonics more than women, a man presenting desquamation of the skin on the palm and finger tips accompanied by vesicles should be questioned about a hair tonic. The use of arsenic in hair tonics has undoubtedly caused more cases of arsenic poisoning than those reported. Cole¹⁷ reports a severe dermatitis from a hair tonic containing arsenous oxide, 1.06 grams (0.068 Gm.) to the fluidounce. Cole quotes Newcomb as stating that in sixty-six toilet preparations he found that forty-six were free from wood alcohol. Perhaps with repeal, grain alcohol will not be so valuable.

Silver with its aftermath of that disfiguring condition called argyria should be warned against, and the use of potassium cyanide and oxalic acid as a hair bleach should be a criminal offense.

In all the vast array of literature, occasionally one finds an article defending cosmetics, such as Carleton's¹⁸ experiments with vanishing cream, which she tried on forty subjects. In twenty-four it proved harmless, although three of these subjects had naturally dry skin, in thirteen cases, the cream was beneficial and in only one case did the cream cause dryness. McCafferty and Genovese¹⁹ experimented with cold creams and vanishing creams on a group of twenty-five and stated that there was not one case of dermatitis produced from the use of vanishing or cold cream of a special formula. Cold cream is for the most part innocuous and is prepared from a vegetable or mineral oil such as almond oil, beeswax or liquid petrolatum, to which is added a small amount of borax to aid emulsification. Some manufacturers add spermaceti, which produces a very white cream but which is liable to become rancid and cause irritation, the quality depends on the fineness of the fats. Vanishing cream in reality belies its name, for it does not vanish. It serves as a greaseless, adhesive surface on which powder is spread. The two creams differ in that the vanishing cream is an emulsion of stearic acid in water containing soap, and cold cream is an emulsion of water in oil containing wax.²⁰ Vanishing cream should never be allowed to remain on the face.

Women at a certain age will dye their hair, and dangerous dyes should be pointed out. Perhaps one of these forbidden dyes is desired; it still can be used if the patient submits to a patch test.²¹ This test should be applied on every occasion before the dye is used. While Negresses are trying to remove the curl and kinks from their hair by the use of gluey substances such as acacia and quince seed, at the same time white women are striving for this effect by the use of permanent waves. The action of permanent waving depends on the softening action of an alkali on the cuticle of the hair. Permanent waves are made by winding the strands of hair on a rod, either spiral or croquemale, which in turn is wrapped in cloths saturated with an alkali, frequently ammonium hydroxide. Over these spindles are placed steam cylinders that are electrically wired and attached to a large stand. The hair should be tested first to determine the time needed

to produce a wave, the scalp is protected by non-inflammable shields placed close to the scalp at the base of the rod. Occasionally, one rod gets too hot or the shield is defective and small burns result. The results seen at the office vary from a superficial blistering to the involvement of the entire epithelial layer, with scarring and permanent alopecia as shown in the accompanying illustration. They are of a characteristic circular appearance about 8 mm. in size.

Rouge is composed mostly of zinc oxide to which chalk and one of the natural dyes has been added. Carmine is used in lipsticks, which are composed of wax, lard and oil of theobroma (cacao butter) in varying proportions.

Henna is probably the safest dye to use on the hair. Wrinkle removers are another group highly advertised and much sought after, they are generally of three types—astrinents, fillers and cauterizing agents. As a rule the astrinents are seldom harmful except those containing phenol (carbolic acid), as to fillers, many are the tragedies of disfigurement that have come from

Typical alopecia and scarring from a burn following a permanent wave (Hair surrounding burn has been clipped by physician.)

the injection of paraffin for the elimination of wrinkles and depressions.²²

Eyebrow pencils rival lipsticks in their popularity, they are, as a rule, harmless and are composed of finely ground carbon made into a pencil of wax or paraffin.

Liquid nail polishes generally consist of acetone containing tincture of benzoin or a solution of cellulose acetate and may be of value, by their antiseptic qualities, in preventing infections that might have resulted from the none too sterile operating tools of the manicurist.

With proper labeling of the various cosmetics and with the cosmetic expert restricting his activities to hygiene, the proper cleansing of the hair, scalp and face, and if requested the application of facial adornments and using pure materials, there will be no loss of business, in fact, there will be an increase, for many women now who fear the use of cosmetics but envy their attractive neighbor may join the ranks, although the American women are rapidly ceasing to look like barbarians and agree that the best face is the natural face.

TELANGIECTASIA ASSOCIATED WITH VARICOSE VEINS

TREATMENT BY A MICRO-INJECTION TECHNIC

H I BIEGELEISEN, MD
NEW YORK

Telangiectases are dilatations of capillaries. They occur frequently in conjunction with varicose veins, being present to some degree in most cases. To date, there has been no satisfactory method of treatment for this unsightly complication. The new method, intravascular injection by a microtechnic, which furnishes the basis of this report, has given satisfactory results.

Varicotelangiectasia must be differentiated from the generalized capillary dilatation occurring in other conditions. The telangiectasia accompanying varicose veins is usually absent before the veins themselves become dilated. Furthermore, it is limited to the lower extremities and the dilated capillaries never project above the surface of the skin. According to Madden's¹ classification, it belongs to the group of secondary telangiectasia.

The shapes assumed by the dilated vessels vary from a straight line to the complex spider web pattern that is often seen. Their color may be pinkish, bright red or dark blue. They are much more frequent in women than in men and are seen in greatest numbers between the ages of 20 and 40 years. Thrombi are seldom encountered in these capillary loops.

The numerous former methods of therapy employed in treatment of this lesion were either ineffective or poor from a cosmetic point of view. They included the use of the cautery, surgical galvanism, multiple linear scarification, radium therapy, radiotherapy, electrodesiccation, and carbon dioxide snow. All these measures give poor cosmetic results, since they involve the production of more or less scar tissue. Furthermore, the dilated capillaries are often present in straight lines many inches long. The use of a skin destroying agent in these cases would cause widespread scar formation. Consequently, there has been a recent attempt on the part of some investigators to eradicate the lesion by the use of subcutaneous perivascular injections of irritating substances. I investigated this perivascular sclerosing method hoping that by its aid I could get improved cosmetic results in my varicose vein cases.

At the outset, it was conceded that if the subcutaneous injection of a harmless sclerosing solution could remove dilated capillaries, this procedure would offer the best method of treatment. Therefore it was decided to make a thorough testing of this technic before other types of therapy were considered. The theory behind this treatment is that the subcutaneous injection of sclerosing fluids will cause the formation of fibrous tissue. The subsequent contraction of this newly formed fibrous tissue should compress the dilated capillaries and thereby remove them completely. The accompanying table illustrates the study that was made in order to determine the effectiveness of this type of treatment.

Before the table is analyzed, it is necessary to explain the technic involved. In most cases the solu-

tion under investigation was injected subcutaneously into the area of capillary enlargement. The fluid was introduced so as to permeate the region thoroughly, the needle point first being placed below and then shifted to the sides of the capillary groups. Whenever possible it was also inserted into the spaces between the individual loops. The average amount of sclerosing solution injected was 2 cc, although the amount varied with the agent used.

A study of the table shows that seventeen different solutions were employed. The first solution used, dextrose and sodium chloride, was given up after one trial on account of the immediate and severe necrosis that resulted in the injected area. Invertose solution was used in four different concentrations, but only with the highest concentration was any degree of fibrosis noted. This was scant in amount and could be felt in the subcutaneous tissue beneath the dilated vessels. There was no evident effect on the telangiectasia.

Neoarsphenamine was then tried on account of its irritating qualities. I vividly remember cases of sphy-

Solutions Under Investigation

Solution Used	Number of Times	Amount	Result
1 Dextrose (25%) and sodium chloride (18%) aa	1	2 cc	Slough 30 mm
2 Invertose 75%	22	0.5 to 4 cc	Occasional slough fibrosis
3 Invertose 60%	70	1 to 5 cc	Usually no fibrosis
4 Invertose 37%	10	1 to 2 cc	No result
5 Invertose 30%	4	1 to 2 cc	No result
6 Neoarsphenamine* 1:20	2	3 cc	Slight fibrosis
7 Neoarsphenamine* 1:10	35	1 to 2 cc	Fair amount of lumpy fibrosis
8 Neoarsphenamine* 1:5	20	1 to 2 cc	Definite fibrotic lump
9 Neoarsphenamine* 1:4	10	1 to 2 cc	Large lump
10 Neoarsphenamine 1:10 and Invertose 60%	4	2 cc	Slight fibrosis
11 Neoarsphenamine* 1:4 and Invertose 75%	2	2 cc	Slight fibrosis
12 Sodium morrhuate 1:3	2	0.5 cc	Slight fibrosis
13 Sodium morrhuate (whole) 5%	4	0.5 to 1 cc	Fair fibrosis
14 Sodium morrhuate and water aa	18	0.5 to 1.5 cc	Slight fibrosis
15 Sodium morrhuate and Invertose 60%	4	2 cc	Slight fibrosis
16 Whole blood	1	1 cc	No result except ecchymosis
17 Fibrinolytic	2	4 minims	Scanty fibrosis
Total	212 injections		

* Stock solution of neoarsphenamine 0.45 Gm in 5 cc of water

lism in which perivascular injections were accidentally made during intravenous administration of this preparation. In each instance, a pronounced lumpy fibrosis resulted which lasted for weeks. It was decided to make use of the sclerosive quality of neoarsphenamine in these experiments. As shown by the table, varying degrees of fibrosis were obtained with neoarsphenamine, especially in the more concentrated solutions in which actual lumps were formed. However, in spite of the marked induration and fibrotic contraction that resulted no change occurred in the telangiectatic capillaries.

With the other solutions used, similar results were evident. Occasionally, fibrosis was produced, but no improvement in the capillary blemishes resulted. Furthermore, in no case was capillary thrombosis seen following the use of any of the seventeen solutions. The subcutaneous method was, therefore, a complete failure.

It was then decided to use intracutaneous injections in order to get the sclerosing action directly in the field of capillary enlargement. It was felt that perhaps the usual subcutaneous injection placed the irritating fluid

2 Kovacs Richard. Electrotherapy and the Elements of Light Therapy. Philadelphia Lea & Febiger 1932.

too far below the papillary capillaries to exert any direct influence on them. A series of intradermal wheals was raised, 60 per cent invertose solution being used. No vascular obliteration occurred.

Failing to influence the telangiectasia with an ordinary wheal I decided to try a high pressure intracutaneous injection. This was done in the following

Fig 1—Telangiectasia before treatment

manner. The injection was not stopped when a wheal was formed but was continued past this point. The forceful introduction of fluid placed the artificially created intercellular space under high pressure. This procedure caused the appearance of an interesting phenomenon. The wheal did not become appreciably larger. Instead, the injected fluid was seen to enter the dilated capillaries nearby, displacing the blood column in them. Evidently, an intravascular introduction of fluid had taken place in spite of the fact that the needle point was in the intradermal wheal.

This curious result has no clear explanation. The intimate connection between the lymph spaces of the skin and the capillaries is well known.³ The density of the perivascular tissues in this region is relatively great on account of the abundance of collagenous and elastic fibers. Furthermore, it has been shown that injury to the capillary wall makes it much more permeable.⁴ All these factors probably operated to cause the phenomenon, but the exact route of the injected liquid from the wheal into the capillary circulation is not known.

With this technic, a definite result on the capillaries was evident for the first time. In a few cases, thrombosis was secured and caused the subsequent disintegration of the affected tiny vessels. However, in about 50 per cent of the cases, necrosis took place at the site of wheal formation, even with the use of invertose solution in dilute form. It was therefore necessary to discontinue this method of treatment.

At this stage of the investigation, it was evident that in order to remove dilated capillaries it was necessary to bring sclerosing fluid in direct contact with endothelium. Consequently, the tiny vessels would have to be injected intravascularly. Ordinary methods of injection

would not answer this purpose. It was necessary to develop a new and finer technic, which will now be described.

MICRO-INJECTION TECHNIC

For this technic the necessary equipment includes (a) proper illumination, (b) extremely fine metal needles, and (c) a powerful binocular loupe.

The light is very important. It must be strong and so arranged as to avoid shadows. A shadow-free operating room lamp is ideal. If this cannot be procured, a good headlamp will also answer the purpose. Proper magnification, as afforded by a good binocular loupe, is indispensable, since the affected blood vessels are too small to be injected by the naked eye. The needles should be the thinnest and finest attainable.

The patient stands on a table so as to distend the capillary loops. No tourniquets are necessary. After the injection is completed, an ordinary gauze pad, held down by adhesive plaster, should be applied.

The blood vessels dealt with stand out clearly when magnified by the binocular loupe. They are either true capillaries, capillary venules, or small venules. No effort was made to distinguish between the various types, since they are difficult to differentiate even under the microscope. It has been stated before that the tissue surrounding these dilated tubules is of greater density than that of the subcutaneous tissue beneath. This fact is of importance because it helps materially in the actual injection. The papillary capillaries are surrounded by dense structures. Above and to the sides lies the highly cellular epidermis with its papillary projections. Below is a dense structure composed of interlacing fibrous and elastic tissue fibers. The tiny vessels are held firmly and do not roll away from the needle point. They are transfixed with comparative ease if the proper technic is used.

The injection should be started in healthy tissue. The fine needle point is carried toward the offending capillary, being kept near the skin surface so that it will engage the vessel directly under the epidermis. With experience, one should be able, by a gentle but firm push, to catch the needle point in the capillary wall and enter its lumen. This procedure, although delicate, is not difficult and very often capillaries of smaller diameter than the needle itself can be entered successfully, owing to the elasticity of the vessel wall.

Fig 2—Telangiectasia after treatment by micro-injection method.

When the needle has been successfully engaged in the capillary, the fluid is injected rapidly, causing the vessels to swell visibly. The sclerosing solution can usually be seen as it displaces the blood in the telangiectatic tubules. Care must be observed to avoid a perivascular injection. This will be evidenced by the formation of a wheal and it is a signal to stop the

³ Sutton R. L. Diseases of the Skin ed 7 St. Louis C. V. Mosby Company 1928.
⁴ Krogh A. The Anatomy and Physiology of Capillaries rev. ed. edition New Haven Conn Yale University Press 1929.

injection in order to avoid a slough. Quinine should not be used, because it is often followed by pigmentation, which may be more unsightly than the telangiectasis itself. Sodium morrhuate, 5 per cent, may be used, but caution must be observed, since it is occasionally capable of slough production, as described by me in 1933.⁵ Any of the other mild sclerosing agents are also satisfactory for this technic.

In some cases, a successful treatment is followed by an almost magical disappearance of the capillary groups. This is especially true of spider web formations or similarly connected clusters of capillaries. In other cases, thromboses will occur and be evidenced by firm dark stripes corresponding to the blood vessels injected. These are easily seen through the thin layer of epidermis covering the thrombotic streaks and are slowly but definitely absorbed in a few weeks. The final reaction in every case is a definite, clean, scarless removal of the offending capillaries.

Fig. 3—Association of telangiectasia with varicose veins

The method described is safe and efficient. With proper technic, one can always secure a positive removal of the offending capillary dilatations. It is being extended to other flat angiomas in the expectation that equally good results will be obtained in these hitherto difficult cases.

CONCLUSIONS

- 1 Telangiectases or dilated capillaries are often present on the lower limbs of patients exhibiting varicose veins.
- 2 Previous methods of treatment have been ineffective or have given poor cosmetic results because of scar formation.
- 3 The subcutaneous perivascular injection of sclerosing fluids is useless in varicotelangiectasia.
- 4 The micromethod of intravascular injection presented successfully removes dilated capillaries.
- 5 The method is safe, does not cause scar formation and gives good cosmetic results.

ACUTE GONOCOCCIC PERITONITIS OF THE RIGHT UPPER QUADRANT IN WOMEN

THOMAS FITZ-HUGH JR., MD

Assistant Professor of Clinical Medicine, University of Pennsylvania
School of Medicine
PHILADELPHIA

In 1930 Curtis¹ in a paper on a cause of adhesions in the right upper quadrant, drew the following conclusions:

1 Extensive adhesions between the anterior surface of the liver and the anterior abdominal wall, characteristically of the separate "violin-string" type, are not infrequently encountered in patients operated on for relief of pelvic distress incident to gonorrheal disease of the tubes.

2 It would appear that gonorrheal disease is not so invariably limited to the pelvis as has heretofore been assumed.

3 Female patients with symptoms suggestive of gallbladder disease or pleurisy may be suffering from liver-abdominal wall adhesions complicating a pelvic gonorrheal infection.

The following three cases, encountered within the past six months in the practice of an internist, would seem to represent instances of the hitherto undescribed acute and early manifestations of gonococcic peritonitis of the right upper quadrant. They would seem to complete the picture of the condition previously described in the end stage by Curtis.

REPORT OF CASES

CASE 1—Miss X, aged 31, seen in my office, Nov. 3, 1933, complained of severe pain all around the right lower rib margin. It was most intense in front over the gallbladder area. Examination showed marked right upper quadrant rigidity and exquisite tenderness. There were no pulmonary or pleural signs or symptoms. A tentative diagnosis of acute cholecystic disease was made. This diagnosis was partially confirmed the next day by a cholecystographic report of "nonfunctioning gallbladder." The patient was hospitalized and Dr. I. S. Ravdin, in consultation, agreed with the diagnosis. After the patient had been in bed ten days, the pain, tenderness and rigidity having partly subsided, Dr. Ravdin operated. To our astonishment we found a normal gallbladder. An unusual, localized fairly dry peritonitis involved the anterior surface and edge of the liver and the adjacent peritoneal surface of the diaphragm and the anterior abdominal wall. The peritoneum in these areas was injected and had the appearance of salt sprinkled on a moist surface. A small section of the liver was taken for biopsy, a peritoneal culture was made, a drainage tube was inserted in the subhepatic fossa, and the operation was terminated after palpation of the appendix, pelvic organs, stomach and duodenum. No abnormal changes were noted in these organs.

After cogitating overnight, we decided that what we had seen was probably the acute stage of the process described in its chronic form by Curtis. Accordingly, smears were made from the drainage tract and we were promptly rewarded with the finding of a beautiful spread of typical gram-negative intracellular biscuit-shaped diplococci (fig. 1).

The patient made an uneventful recovery. When we told her the results of our examination she related the following remarkable story. Five years previously she had been desperately ill in another hospital, first with gonorrheal salpingitis and then with gonococcic septicemia. Two separate blood cultures had shown the gonococcus. She was treated by such measures as transfusions and the administration of antiserum. She finally recovered completely, much to the surprise of every one concerned. She had not told us this story prior to operation because she had been assured that all the smears and tests had become absolutely negative and she did not think that the old condition could cause her trouble in the future.

GONOCOCCIC PERITONITIS—FITZ-HUGH

2095

She stated that there had been no possibility of subsequent exposure

Our own efforts to find the gonococcus in smears from the cervix and urethra after operation were negative. No palpable evidence of pelvic disease could be demonstrated. The blood Wassermann and gonococcus complement fixation tests were negative at the time of her discharge from the hospital. The sedimentation curve showed marked acceleration, even after a week in bed, and at a time when most of the symptoms had become quiescent. The section from the liver showed a partly organized and partly acute "inflammation of the capsule with a parenchymal involvement" (fig 2). A few diplococci were seen but were not definite enough to permit a diagnosis from tissue itself. We were in no doubt, however, as to their nature in view of the smears from the peritoneal exudate. The patient is at present entirely well and has had no trouble except that the first postoperative menstrual epoch was stormy, with fever for a few days, unusual cramps, menorrhagia and dysuria. She recalled the fact that similar symptoms accompanied the period preceding the present illness.

Case 2—Mrs. Y., aged 30, was seen February 6 in consultation with Dr. Mackinnon Ellis, to whom I am indebted for the following details. The patient was the mother of two healthy sons, aged 5 and 6 years, and had been divorced three years before. She had been sick for several weeks with symptoms suggestive of "intestinal grip," such as low abdominal pain, distention and fever. The fever ranged from 98 to 101 F. lasting a few days and then subsiding to such a point that she "went out and had a few high-balls" against her doctor's orders. A relapse occurred. The temperature was higher than it had been before and there was generalized abdominal pain, distention, great sensitiveness and some rigidity. These symptoms partially subsided after about a week, when the patient was seized with severe acute pain in the right upper quadrant of the abdomen. Dr. Ellis found localized rigidity and marked tenderness. He suspected an acute cholangitic complication of the grip. The temperature rose to 103 and subsided up and down for a few days, when it began to sub-

syndrome. The patient, on being informed of our diagnosis, showed no trace of righteous indignation. She seemed anxious, however, to establish the possibility in our minds that the original infection might have occurred "some years ago."

Dr. Ellis made a pelvic examination during the early stages of the pain in the lower part of the abdomen and found nothing abnormal. She was menstruating at the time of my consultation. About five days later Dr. Ellis obtained smears from the cervix, which Dr. W. P. Belk reported as positive

Fig. 2—Section under low power showing hemorrhage and fresh exudate at surface organized exudate below and normal liver tissue at the bottom and left

Fig. 1—A typical oil immersion view of a smear from the peritoneal exudate showing a cell packed with gram-negative diplococci

side and the pain, distention and rigidity gradually disappeared. It was at this juncture that I saw the patient. My examination revealed nothing except slight tenderness in the right upper quadrant and suprapubic region and a slightly elevated temperature. Questioning brought out the fact that a week prior to onset of the low abdominal pain and the fever there had occurred well marked leukorrhea and some dysuria which had lasted for a few days. I told Dr. Ellis the story of the first case reported in this paper and we agreed that his patient probably had the same

for gonococcus. A week later Dr. F. E. Keene found clinical evidence of gonorrhea in his examination of the cervix and stated also that the left ovary was inflamed. He, too, obtained positive smears from the cervix.

The patient made an uneventful recovery. The urinalyses, January 4 and 16, were negative. The blood count, February 8, showed red blood cells, 3,500,000, white blood cells, 8,800, and hemoglobin, 87 per cent. The differential blood count showed neutrophils, 69 per cent (19 per cent nonfilament), lymphocytes, 25 per cent, monocytes, 3 per cent, eosinophils, 1 per cent, and basophils 1 per cent. February 8, the gonococcus complement fixation test was negative and the sedimentation curve showed marked acceleration (20 mm fall in twenty minutes and 25 mm. fall at the end of an hour).

CASE 3—Miss Z., aged 34, presented a picture almost identical with that of patient 2 except that I had the opportunity of examining her during the latter part of the acute stage of the localization of the pain in the right upper quadrant. Her contribution to this syndrome, beautiful "new snow" creaking frictions audible all along the right upper margin of the anterior abdominal wall, is perhaps of considerable importance. She, too, had had an irregular moderate elevation of temperature for three weeks with prodromal symptoms of leukorrhea and dysuria, followed by low abdominal pain, rigidity and distention prior to the sudden severe localization of symptoms in the right upper quadrant. There was marked acceleration of the sedimentation rate, little or no leukocytosis and a moderate secondary anemia. The complement fixation test was positive. The pelvic examination subsequently revealed no gross abnormalities. After rest in bed for three days, the frictions disappeared and after one month from the onset she had recovered entirely. One of three cervical smears showed the typical gram-negative intracellular diplococcus. She admitted the probable correctness of the diagnosis but could not assign a likely date of contact.

COMMENT

The first case is the only one in which there is real proof of the presence of acute gonococcic peritonitis

Even here it must be admitted that the proof is incomplete in that no cultural identification of the gram-negative biscuit-shaped diplococcus was undertaken. There seems to be no reasonable doubt, however, that this was acute gonococcal peritonitis. In the two subsequent cases, in which the diagnoses were made only on the basis of experience from the first case, there is no personal doubt that the same peculiar localized gonococcal peritonitis existed in the right upper quadrant.

From the admittedly incomplete data at hand the clinicopathologic picture is reconstructed in the following manner. At some indefinite time presumably following a previous gonorrheal infection, or possibly a reinfection, there occurs a brief period of leukorrhea, slight transient dysuria, cramps and perhaps a somewhat abnormal menstrual epoch. This train of symptoms suggests that a mild pelvic reactivation has occurred. Vague low abdominal pain, distention and slight irregular fever follow promptly. Within from one to three weeks, sometimes after a brief interval of apparent quiescence, there occurs acute severe pain in the upper part of the abdomen with distention and rigidity, which quickly localizes in the right upper quadrant. The pain in the right upper quadrant, rigidity and febrile relapse last for from a few days to a week and simulate very closely the picture of acute hydrops or acute empyema of the gallbladder. The pain is made worse by coughing, sneezing, laughing or twisting the trunk muscles, and it is not relieved by strapping the lower part of the chest. A quiet deep breath does not cause much pain and the diaphragm moves fairly well. The peristaltic sounds are normal or only slightly diminished. The anterior abdominal wall below the right costal border is rigid and exquisitely sensitive. A crunching to and fro type of friction may be readily heard just over this area of the abdominal wall, at least during the subsiding stage of the acute process. The fever, pain, distention and rigidity subside within from three to six weeks from the first onset of symptoms. After this the "chronic stage" begins, which may be symptomless or characterized by the later manifestations described by Curtis. The prognosis for recovery from the acute stage is uniformly good, and the ultimate outlook as to life itself is apparently equally good. It would seem probable, however, that recurrent gonococcal invasions of the right upper quadrant might occur in certain cases.

During the stage of acute peritonitis in the upper part of the abdomen there is little or no leukocytosis and only a moderate "left shift" in the neutrophil formula. There is, however, a marked acceleration of sedimentation rate. The gonococcus may be obtained from the peritoneum during the (subsiding?) acute stage if one is fooled into operating. The gonococcus may or may not be obtained subsequently from the cervix or the urethra. A reasonable doubt as to the diagnosis must remain if the organism is not demonstrated. Sometimes in these cases there is apparently no gross evidence of residual gonorrhea in the pelvis. The gonococcus complement fixation test is not helpful (negative in two instances and positive in one during convalescence from the acute phase).

It should be emphasized that these cases do not seem to fit the picture of the previously reported² instances of virulent generalized acute gonococcal peritonitis, which is said to be very uncommon.

The clinical manifestations of this syndrome would seem to be rather clear cut. It is probably true that internists and general practitioners, who would be the most likely observers of the condition, have overlooked a number of these cases. It is obvious that the differential diagnosis of the condition must include a careful consideration of basal pleurisy, pneumonia, "intestinal grip," "devil's grip," colitis, cholecystitis, perforating peptic ulcer, pyelitis, an early stage of shingles, appendicitis and all forms of peritonitis. On the operating table the appearance of the lesion has a greater resemblance to a mild localized "zuckerkuß" change with little or no fluid than it has to an acute peritonitis. It should not be necessary, except in unusual circumstances, to establish the diagnosis at operation.

SUMMARY

1 In three cases of what is believed to be acute gonococcal peritonitis of the right upper quadrant in young women, the clinical and pathologic features are sufficiently distinct and uniform to justify the belief that the diagnosis may sometimes be made without great difficulty.

2 These cases, which represent the acute stage, help to complete the picture of the condition the end stage of which has been described by Curtis as "violin-string" adhesions between the anterior surface of the liver and the anterior abdominal wall occurring in women with present gonorrheal salpingitis or a previous history of that condition.

Clinical Notes, Suggestions and New Instruments

TRAUMATIC INFECTED INTERSTITIAL MYOSITIS AS A CAUSE OF PARANEPHRIC ABSCESS

ALFRED BROWN, M.D. OMAHA

Professor of Surgery University of Nebraska College of Medicine

In December 1927¹ I called attention to the occurrence of an abscess of the lumbar region which was situated outside the perirenal fat in a space bounded in front by the posterior parietal peritoneum and perirenal capsule, behind and laterally by the deep muscles of the back, above by the diaphragm and below by the lower boundary of the false pelvis. This type of abscess I considered to be due to trauma in the form of a muscle strain or contusion which caused a tear either of the muscle fibers themselves or of the capsule of the muscle, from which a localized area of hemorrhage or exudate resulted. Subsequent infection of this area caused the abscess. Two cases were cited which appeared to bear out this hypothesis, which at the time was offered as a hypothesis without definite proof. In the paper I wrote "If this assumption of hemorrhage as the causative factor in this type of abscess is correct, and it seems to be most reasonable, it is questionable whether these abscesses should be classified as true paranephric abscesses or rather as abscesses of the paranephric body of Zuckerkandl and Gerota, which is a continuation of the subperitoneal fascia of the abdominal wall and lies outside the true perirenal fat."

If hemorrhage results from muscular violence, such as a sudden strain which is presupposed in this condition, it would come from the tearing apart of a few muscle fibers resulting from the sudden violence. The blood escaping from the surface of the muscle would enter the fatty layer covering this surface and would not reach the perirenal fat as it would not perforate the fascia of Gerota unless that structure were

² Norris, C. C. *Gonorrhea in Women*. Philadelphia: W. B. Saunders Company, 1913. pp. 355-360.

¹ Brown, Alfred. *Retroperitoneal Lumbar (Paranephric) Abscess*. J. A. M. A. 90: 666-668 (March 3) 1928.

torn, and a tear of this fascia, because of its mobility, would not be apt to occur from muscular violence."

As can be seen from the foregoing description, the etiologic factor was purely an assumption and at the time was offered without proof other than deduction. Since that time, however, I have had the opportunity of studying a case of trauma to the back which furnished material not only clinical but also pathologic, which seems to demonstrate conclusively that this

Fig 1—Section under low power showing collection of round cells, destruction of muscle fibers and newly forming connective tissue

type of abscess is the result of muscle trauma in the position described and that the assumption offered is correct

REPORT OF CASE

D B, a schoolboy, aged 15 years, admitted to the University Hospital, Nov. 23, 1929, complained chiefly of pain in the right side of the abdomen, front and back, and in the region of the right kidney.

October 16, five weeks and three days before, the patient was hit in the back with a chair while scuffling in school. For about thirty seconds following the blow he was dazed and paralyzed, after which he fell in a chair and felt a sharp pain in the right kidney region. After two or three minutes he got up and after five or ten minutes the pain had left him. Four days later, October 20, the patient began to feel a dull aching pain, which lasted five days, at which time, the patient said, relief was obtained by a visit to an osteopath, who stated that he replaced four vertebrae which had been knocked loose. This same afternoon, October 25, the patient's arm was accidentally jerked, and he nearly lost his balance, bending his back, again causing pain. Three or four days later he had the "flu," which made the pain quite severe.

Some time during the first week of November he noticed a soft sore mass in the right upper quadrant of the abdomen. This increased in size and soreness for several days, until it became very painful except when he kept his breathing very shallow. About November 10 it felt as if this mass had broken, and his symptoms were greatly relieved. For two or three days before and after this feeling of the mass breaking he had coughed once or twice each morning and brought up a yellow sticky material that contained blood, which was sometimes bright red and at other times dark red. A few days after the apparent breaking of the mass the patient felt a hard lump in the right side of the abdomen which he could move easily nearly over to the midline and into the right upper quadrant. This mass was very sore on palpation. It felt about as big as a hen's egg. A few days later the lump could not be found by the patient. It had last been pushed to the right upper quadrant. About the same period, during which the patient could feel this lump, he states that when he pressed along the hip on his right side it felt as if he was forcing fluid from this region.

He had had only slight pain since the breaking of the first mass and had practically none on entrance to the hospital.

He was advised to enter to have an abscess in the right side of the abdomen drained.

Since the accident the patient had lost 27 pounds, or 113 Kg, his weight having dropped from 149 to 122 pounds, (67.6 to 55.31 Kg). This he attributed largely to pills that he had been taking for about a week and a half, which caused about six to ten bowel movements a day.

The previous history was good. He had had his tonsils removed, had sprained an ankle and had a few minor injuries in the fall, otherwise he had always been well. He had never had any burning on urination, frequency, retention or nocturia.

The family history was negative.

Physical examination by the house surgeon was negative except locally, which disclosed a very evident tenderness on palpation in the right upper quadrant posteriorly. A palpable mass in this region gave the impression of being part of or the entire right kidney.

The patient's temperature ranged from 98.6 to 96 F. Most of the time it was subnormal. The pulse varied during the days of examination from 60 to 96, with a variation of about 20 beats each day. The respirations were from 18 to 22.

The day following admission the urine was clear, the specific gravity was 1.020, the reaction was acid and there was no albumin, no dextrose and no acetone. Microscopic examination showed debris, a few leukocytes and a few epithelial cells.

The day after admission the blood count was: red blood cells, 4,940,000, hemoglobin, 80 per cent, leukocytes, 13,800, polymorphonuclears, 75 per cent, lymphocytes, 24 per cent, transitional cells, 1 per cent. December 1, the leukocytes numbered 14,000, December 4 (two days after operation) there were 14,300, December 10 (eight days after operation) there were 7,700, with polymorphonuclears, 61 per cent, and lymphocytes, 39 per cent. The Wassermann reaction was negative.

The presence of a paranephric abscess was suspected and measures were taken to determine the condition of the urinary tract.

In a report on the roentgenograms, November 26, Dr. James S. McAvoy stated that studies made with special references to the kidney, ureter and bladder tract did not demonstrate any gross bony abnormality. The kidneys were markedly obscured by gas, especially on the left side, that on the right showed no

Fig 2—Section under low power showing interstitial myositis with milary abscess

appreciable increase in size. There was no evidence of renal calculi.

November 29, ureteral catheterization was performed by Dr. C. A. Owens, and Dr. Carleton B. Peirce made the following report on a pyelogram:

"Ureteral catheterization on the right side followed by injection demonstrated a rather large renal pelvis, the minor calices having short thick necks the cusps rather shallow. There is an apparent incomplete filling of the inferior calices. The outer margin of the kidney is well defined. We would be curious

about the urinary findings as possibly indicating some localized pathology causing the defect in the inferior calyx which we cannot attribute to inadequate pressure"

In the light of the conditions found at operation the roentgen examination is of great interest, showing as it does a squeezing of the calices of the lower pole of the kidney by the pressure of a mass outside the perirenal fat

Operation was performed, December 2 The preoperative diagnosis was hematoma in paranephric space, infected, and the postoperative diagnosis was the same

An oblique kidney incision was made over the right kidney and deepened to the perirenal capsule (fascia of Gerota) At the lower part of the incision opposite the fourth lumbar spine, a definite mass of material consisting of broken down blood clot and a small amount of pus surrounded by newly formed connective tissue was found in and in front of the psoas and quadratus lumborum muscles This extended up to and involved the lower portion of the perirenal capsule, but the perirenal fat and kidney were uninvolved A fragment of the wall of the abscess was removed for microscopic examination, a cigaret drain was inserted and the wound was closed

The material consisted of a small portion of muscle which in part appeared to be replaced by connective tissue

Microscopic examination disclosed that adjoining one surface of the muscle was a dense exudate of fibrinopurulent material

Fig 3—Interstitial myositis under high power

associated with an underlying overgrowth of connective tissue both of mature and of fibroblastic cells In the muscle itself there was considerable amount of connective tissue overgrowth associated with numerous focal areas of leukocytic infiltration, as shown in the accompanying illustrations

The pathologic diagnosis was acute and chronic interstitial myositis

The postoperative convalescence was rapid and uneventful, and the patient was discharged on the eighth postoperative day with the wound almost healed

December 21, eleven days after discharge, the patient returned to the follow-up clinic and the report made at that time stated that the condition was wonderfully improved The patient had gained 26 pounds (11.8 Kg) and the wound was in excellent condition

CONCLUSIONS

It would seem clear from the observations made in this case that there exists a type of traumatic abscess of the back involving the contents of the paranephric space which is due to muscle trauma accompanied by hemorrhage The first result of the trauma is interstitial myositis in which, if infection follows, small abscesses form which may coalesce and, with the infected hematoma, form a large abscess

This type of abscess is separate and distinct from the abscess involving the perirenal fat and might more properly be designated "paranephric" than "perinephritic" abscess

NEUTROPENIA FOLLOWING THE ADMINISTRATION OF AMIDOPYRINE REPORT OF A CASE

I S ZINBERG MD LAWRENCE KATZENSTEIN MD, AND
L E WICE MD, BALTIMORE

A W, a Jewish woman, aged 46, admitted to the private medical service of the Sinai Hospital, March 1, 1934, complained of fever, cough, and shortness of breath, of seven days' duration

The family history was unimportant The only noteworthy events in the past history were an appendectomy twenty five years previously and an uncomplicated pneumonia in March 1933 A review of the systems shows the patient to have been

TABLE 1—Blood Counts to March 13

	White Blood Cells	Polymorphonuclear Leukocytes, per Cent
On admission	17,000	96
March 2	19,300	90
March 3	24,100	96
March 4	20,200	91
March 6	11,500	84
March 13	7,850	78

in good health except for high blood pressure with headaches during the last ten years These headaches have been relieved by one or two tablets of acetylsalicylic acid However, about five years before the patient was given a white pill, other than acetylsalicylic acid, for a headache About an hour later she had a severe chill lasting fifteen minutes As both the physician who wrote the prescription and the pharmacist who filled it are now dead, the identity of the "white pill" must remain a mystery With this one exception, the patient states that she has taken no other sedatives or antipyretics besides acetylsalicylic acid and codeine

The present illness started, Feb 23, 1934, with a chill, fever, cough, expectoration of rusty sputum, and shortness of breath During the following week these symptoms increased in severity, and the patient was hospitalized, March 1

On physical examination the patient was obese and acutely ill and presented typical signs of pneumonia of the left lower lobe Aside from a loud blowing systolic murmur at the apex of the heart and moderate abdominal distention, the remainder of the examination was negative

Laboratory examination revealed red blood cells, 4,100,000, hemoglobin, 85 per cent (Sahli), white blood cells, 17,000, polymorphonuclear leukocytes, 96 per cent, lymphocytes, 4 per cent All cells appeared normal Examination of the urine and stool was negative, blood sugar was 114 mg per hundred cubic centimeters, and the blood urea was 35 mg The blood Wassermann test was negative Typing of the sputum showed pneumococcus type I

TABLE 2—Blood Counts March 28-April 10

	White Blood Cells	Polymorphonuclear Leukocytes, per Cent	Meta myelo cytes, per Cent	Lympho cytes, per Cent	Mono cytes, per Cent
March 28	4,200	25	4	68	3
March 30	8,700	53	2	44	1
April 3	8,800	49		48	3
April 10	8,400	67		31	2

After three weeks the temperature was normal, and there was no longer evidence of pneumonia The blood counts during this period are given in table 1

During this time the patient received no antipyretics out was given the following barbiturates two dial-Ciba tablets, March 4, 1½ grain (0.1 Gm) of phenobarbital, March 5 and 6, 7½ grains (0.5 Gm) of barbitol, March 9 to March 12 and daily from March 13 to 16, 1½ grains of phenobarbital, March 20, and 5 grains (0.3 Gm) of barbitol, March 22, 23 and 24

March 25 at 10 55 p. m. the patient had a chill lasting about ten minutes with a subsequent mouth temperature of 100 F The only complaint was marked weakness, and examination showed nothing noteworthy The next day the temperature was normal Because of a headache 5 grains of acetylsalicylic

acid and 5 grains of amidopyrine were given at 1 25 p m. Five grains of barbital was given at 9 o'clock. The next morning, March 27, the patient had a chill lasting about five minutes, with no other objective changes. That afternoon the blood count was white blood cells, 2,700, polymorphonuclears 28 per cent, lymphocytes, 71 per cent, monocytes, 1 per cent. Succeeding counts are given in Table 2.

From March 28 to April 10, the convalescence was uneventful. No antipyretics were given, and the only sedative used was codeine.

TABLE 3—Blood Counts April 11-April 14

	White Blood Cells	Polymor- phonuclear Leukocytes, per Cent	Lympho- cytes, per Cent	Mono- cytes, per Cent
During the chill				
At 9 30 p m	4,600	18	80	2
At 3 40 p m	1,300	47	56	1
At 4 40 p m	1,500	42	53	
At 8 40 p m	1,400	49	51	
April 10	2,200	18	80	2
April 13	4,200	37	60	3
April 14	7,800	36	61	2

April 11 at 1 30 p m 5 grains of amidopyrine was given. At 2 45 p m the patient had a severe chill lasting fifteen minutes, with a subsequent rise in mouth temperature to 101.4 F. Later in the afternoon she became perfectly comfortable and has suffered no ill effects whatever from the experience.

The blood counts at this period are given in table 3.

REACTIONS TO CERTAIN BARBITAL DERIVATIVES

FLORENCE L. MEREDITH, M.D., BOSTON

The following case has a bearing on the subject recently discussed by Loveman.¹

A white woman, aged 39, took one allonal (allylisopropyl-barbituric acid with amidopyrine) tablet at night Jan 28 1928. In the morning she noticed three roundish inflamed areas one each on the front of the neck, the side of the neck and the inner aspect of the midhigh region. They were deeply red in the center and shaded off into the normal skin. They itched slightly and felt warm subjectively and objectively. She applied an ointment, and in three or four days the diffuse redness and itching had disappeared, leaving, however, clearly defined reddened areas about 1 inch in circumference. Because those on the neck were disfiguring, she consulted a dermatologist who made a diagnosis of cryptococcc infection, prescribed medication to produce epidermal scaling and disinfection, and told her that it would probably be years before they entirely disappeared.

She used the medication faithfully for several weeks but discontinued it finally, as it seemed to her to perpetuate the redness. Scaling occurred to some degree but without any change in the underlying tissue. Itching continued as long as the medication was used.

After she stopped all forms of treatment, the lesions finally settled down to clear-cut rather deeply pigmented brownish areas. Although aware of the fact that the first lesions had followed the taking of allonal, about six weeks after the lesions first appeared she again took allonal, with the result that the three original lesions reappeared exactly as they did at first.

She has not taken allonal since then but exacerbations have occurred as follows. Sedormid caused an exacerbation which appeared slowly after four or five nightly doses, dial, after one dose, phenolphthalein, contained in a liquid petrolatum preparation, after one dose, sodium amytal after one dose. The latter caused the most violent reaction of all. Amidopyrine (Pyramidon) has never caused trouble. No new lesions of the type under discussion have occurred. Each time they reappeared the redness has faded more rapidly than on the previous occasion. These three lesions have finally become nearly normal. First, minute punctate areas of normal color appeared and now only minute punctate areas of pigmentation

¹ Loveman, A. B. Experimental Aspect of Fixed Eruption Due to Allurate a Compound of Allonal. J. A. M. A. 102:97 (Jan 13) 1934.

are present which are scarcely visible. A slight exacerbation occurred during the summer of 1933 in connection with sunburn of the neck followed by deeper pigmentation in these areas than elsewhere, but as the tan faded, the final effect on these areas seemed to have been good.

Jan 25, 1934, a physician in another city prescribed Belledenal "Sandoz" as an antispasmodic. The next morning she reported that the three original lesions had reappeared, with considerable redness and itching. She took one-half tablet (each Belledenal tablet contains 1/2.00 gram [0.00025 Gm] of bellafoline, or belladonna alkaloids as malates and three-fourths grain [0.048 Gm] of phenobarbital). A week later she reported that the reaction had been intense but had subsided in three days, leaving the areas more nearly normal in appearance than they had been since 1928.

Prior to the appearance of the three lesions mentioned, the patient had been subject to a skin eruption similar to acne rosacea together with slight swelling of the forehead and hands, severe headache and digestive "upset." She had never been able to trace these symptoms to the ingestion of any particular food or drug, nor had her physicians been able to find a cause for them. Following appendectomy three years ago she became much less susceptible to these symptoms and has not had them except in connection with the same drugs that cause exacerbation of the lesions under discussion.

SIMPLE CRADLE ATTACHMENT FOR PLASTER CAST OF FOOT

PHILIP LEWIN, M.D., CHICAGO

A simple cradle is useful to protect the toes in cases in which a foot or leg cast is indicated. It is simply the application of a wire or plaster rope wicket to protect the toes. I am indebted to Dr. Arthur P. Picard for the suggestion.

When the cast is complete and just before the stockinet is turned down to make a French cuff, a slit is made on each side of the stockinet. It is turned back, spanning each side of the wicket, and two or three turns of plaster are applied to secure the wicket in position. Plaster rope may be used to secure the contact edges.

The wicket can be made of No. 12 gage galvanized wire shaped by hand, or of plaster rope fashioned by passing a strip

Cradle attachment for plaster cast of foot

of bandage through the partly closed hand. The distance between the ends of the toes and the wicket should be about 1 1/2 inches. The ends of the wire may be curled or bent to afford greater stability.

If desired, the cradle may be made removable by incorporating a clamp on each side of the cast and inserting the wicket when needed. A combination groove and corrugation may be used.

Wire may be used as a core for the plaster wicket. If plaster is used the ends should be spread out fan shape.

The wicket can be modified to function like a banyo splint used in the treatment of lesions of the hand and fingers. It can be used in conjunction with a walking iron. A 50 foot roll of galvanized 12 gage wire can be purchased for 20 cents. The wire of an ordinary coat hanger furnishes excellent material for a wicket.

Therapeutics**THE THERAPY OF THE COOK
COUNTY HOSPITAL**EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE—In their preparation, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft prepared for publication. The series of articles will be continued from time to time in these columns.—ED

THERAPY OF RHEUMATIC FEVER**PROPHYLAXIS**

1 The patient's resistance should be increased by
(a) A nutritious diet, including an abundance of vitamins

(b) The administration of cod liver oil

(c) An outdoor life

(d) Graduated tonic cold hydrotherapy

2 Chilling, especially when fatigued, should be avoided by

(a) Warm clothing (but not to the extent of sweating)

(b) Avoidance of prolonged exposure to cold and wet. Wet garments, especially shoes and stockings, should be changed at the earliest possible moment

(c) One should change to a warm climate. Rheumatic fever does not occur in the tropics

3 Adequate treatment of the primary infection should be given by

(a) Keeping the patient in a warm room if mild symptoms of a cold are present

(b) Absolute rest in bed, if there is a fever, and for as many days of normal temperature as there has been temperature abnormality

(c) Isolation of cases of catarrhal fever, or enforced absence from school on the part of children so infected

4 Removal of foci of infection in

(a) The tonsils. Frequently repeated tonsillitis is an indication for tonsillectomy, or whenever rheumatic fever, chorea or carditis follows tonsillitis, provided there is evidence of infection in the tonsils

(b) Abscessed teeth

(c) Other tissues

TREATMENT

1 Absolute rest in bed should be insisted on

(a) For several (at least three) weeks after the temperature has become normal and the arthritic symptoms have subsided

(b) For several months, if there is any evidence of heart involvement, particularly in children. A walk to the bathroom may bring on a relapse

2 Chilling should be avoided by

(a) Adequate but not excessive bed coverings

(b) Drying the skin and changing (with due care against exposure) the night gown and, if necessary, the bed clothing when these are wet with sweat

3 Analgesics to be employed are the following

(a) While no cure for rheumatic fever and not even shortening the duration of the disease, salicylate is in adequate doses often almost specific in checking pain and joint inflammation. When it fails to do so within

three days, it may as well be abandoned for that particular attack. Salicylization is best accomplished by giving sodium salicylate (prescription 1 or 2) in doses of 1 Gm., 75 per cent for women, from 30 to 50 per cent for children (prescription 3) every hour, generally for eight or ten doses or until pains are relieved, or until salicylism (severe tinnitus, excessive sweating,

PRESCRIPTION 1—Sodium Salicylate

R Sodium salicylate 30.00 Gm
Sodium bicarbonate 60.00 Gm
Divide into thirty powders

Label One powder in a glassful of seltzer water every hour until relieved or until symptoms of intolerance (severe tinnitus, excessive sweating, vomiting, delirium)

PRESCRIPTION 2—Sodium Salicylate

R Sodium salicylate 30.00 Gm
Sodium bicarbonate 90.00 Gm
Divide into thirty blue powder papers

R Citric acid 30.00 Gm
Divide into thirty white powder papers

Label One of each in half a glass of water every hour until the condition is relieved or until symptoms of intolerance appear

PRESCRIPTION 3—Sodium Salicylate

R Sodium salicylate 5.00 Gm
Potassium bicarbonate 10.00 Gm
Cinnamon water 60.00 cc
Syrup of cinnamon to make 120.00 cc

M Label Two teaspoonfuls in water every hour the dose being reduced on the appearance of symptoms of intolerance

PRESCRIPTION 4—Sodium Salicylate

R Sodium salicylate 40.00 Gm
Divide into ten powders

Label Dissolve powder in 4 ounces of thin starch water and use as a retention enema every eight hours

and vomiting, especially prone to occur if there is carditis or delirium) is complained of. Mild sweating or tinnitus may be disregarded. Then a dose may be given every two hours, possibly for two days, every three hours, possibly for three days, every four hours for four days, and so on, the salicylate being continued in this manner, in gradually decreasing dosage, in order to lessen liability to relapse. Recurrence of symptoms calls for prompt resumption of the original dosage, which may not now be as successful. When the salicylate is not tolerated by the stomach, it may be administered by rectum after a cleansing enema (prescription 4).

(b) Amidopyrine (prescription 5) in doses of 0.3 Gm. every hour until pain is relieved, then at slowly but progressively increasing intervals, is indicated in

PRESCRIPTION 5—Amidopyrine

R 30 Amidopyrine tablets 0.30 Gm

Label One every hour until the pain is relieved then every two hours and at gradually increasing intervals

cases that do not respond to salicylate. When this agent is employed, the leukocyte count should be controlled, to forestall the development of granulopenia.

(c) Morphine (see Pain) may be administered hypodermically at once in a sufficient dose to relieve the pain, repeated every four hours in half the preceding dose, and discontinued as soon as the pain-relieving effect of the other remedies has been secured.

4 Resistance should be increased

(a) Alkalis (prescription 6) in sufficient dosage to render the urine alkaline are probably of value in

PRESCRIPTION 6—Sodium Citrate

R Sodium citrate 30.00 Gm
Syrup of orange 60.00 cc
Water to make 120.00 cc

M Label Teaspoonful in lemonade or orangeade or added to dose of salicylate every two hours

antagonizing the tendency to acidosis, which is believed to lessen resistance.

(b) Protein shock therapy is useful in obstinate cases, especially in those with a tendency to relapse, e g, by typhoid vaccine (from 40 up to 75 million) intravenously. It is contraindicated in elderly individuals and those crippled by organic disease.

5 Local therapy includes

(a) Absolute rest to the affected joint by pillows, sandbags or light, easily removable splints (not plaster of paris).

(b) Warmth, e g, wrapping of the affected joints in cotton pads 1 inch thick, 2 or 3 feet long and covering one and one-half times the circumference of the joint, the cotton being placed between layers of gauze and tied on with tapes.

(c) Compresses of hot half-saturated solution of magnesium sulphate.

(d) Rubefaction by means of methyl salicylate (which may be diluted with oil for tender skins) painted on two or three times daily and covered with a cotton bandage.

(e) Blisters (prescription 7) against obstinate pain and tenderness.

PRESCRIPTION 7—*Cantharides Plasters*

R Six Cantharides plasters 1 by 1 inch each

Label Apply one over the most tender point for eight hours. Apply another one over the next most tender point and so on.

(f) Aspiration of joints tensely distended with fluid.

6 The general regimen includes

Water in abundance, a liquid diet during the febrile period, and liberal semisolid and general diet later. Protein need not be restricted.

Laxatives as required.

7 Convalescence may possibly be expedited by the following:

(a) Iron, as in the form of pills of ferrous carbonate (0.3 Gm) may be given three times daily, to each of which arsenic trioxide, 0.002 Gm, might be added (prescription 8), to help in overcoming the anemia.

PRESCRIPTION 8—*Arsenic Trioxide*

R Arsenic trioxide 0.06 Gm
Mass of ferrous carbonate 10.00 Gm

Mix and divide into thirty pills

Label One three times a day after meals

(b) Iodide is believed to be of possible value in the prevention of undue fibrosis. It may be given in doses of 0.3 Gm three times daily after meals. The syrup of ferrous iodide (1 cc) is compatible with iodide and may be combined with it as in prescription 9.

PRESCRIPTION 9—*Potassium Iodide and Syrup of Ferrous Iodide*

R Potassium iodide 10.00 Gm
Syrup of ferrous iodide 30.00 cc
Syrup of orange flowers to make 120.00 cc

M Label Teaspoonful in milk three times daily after meals

PRESCRIPTION 10—*Cod Liver Oil*

R Emulsion of cod liver oil 240.00 cc

Label From one teaspoonful to one tablespoonful three times daily after meals

(c) Cod liver oil (prescription 10) may serve to improve nutrition in a patient much emaciated. It should not be given, however, until the fever has subsided, the appetite has returned, and a liberal amount of food is being taken.

8 Relapses may be prevented by the measures described for prophylaxis. Tonsillectomy is to be considered, but not until the patient has completely recovered and then only if the tonsils are definitely diseased.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
H A CARTER Secretary

SPECIAL COMMITTEE ON PHYSICAL THERAPY OF THE CALIFORNIA STATE MEDICAL ASSOCIATION

A special committee on physical therapy of the California State Medical Association was appointed by the council of the California State Medical Association at its meeting in September, 1932. At that time Dr John Severy Hibben Pasadena, was selected as chairman. Later the four following men from different parts of the state were appointed: Dr Rodney F. Atsatt, Santa Barbara, Dr Howard Naffziger, San Francisco, Dr R. Leslie Langnecker, San Francisco, and Dr Charles L. Lowman, Los Angeles.

One of the reasons advanced for creating such a committee was the suggestion that many members of the medical profession do not fully understand that physical therapeutic agents are a part of the regular professional armamentarium in the practice of medicine and surgery and that those practicing physical therapy should have opportunities to receive ample training and postgraduate instruction given by qualified physicians or teaching institutions other than by salesmen of physical therapy apparatus or commercial lecturers.

The first activity of the committee was to make a survey of all the medical colleges, hospitals and medical societies in the state. A questionnaire was sent to four medical colleges. The returns showed that only two of these colleges offered instruction in physical therapy. Then a questionnaire was sent to thirty-nine county medical societies and each was asked to appoint a special committee to cooperate with the state committee. It was hoped that in this way interest and attention might be directed toward physical therapy, not necessarily to increase the use of it but to improve the quality of that practice. Of the thirty-nine county medical societies, fourteen have already created special committees on physical therapy.

A questionnaire was also sent to fifty-one hospitals in the state. In answer to the question "Do you possess a physical therapy department," thirty-five out of the thirty-nine replied "yes" and four answered "no." The committee offered its advice to the hospitals contemplating establishing physical therapy departments. The committee also suggested to the chairmen of the medical hospital boards having physical therapy departments that they encourage the presentation of papers at the meetings in order to stimulate a better and more intelligent discussion of the value and limitations of the subject.

Numerous papers and lectures were given and films shown before medical societies and hospitals. The committee has also sponsored several radio talks on the subject of physical therapy. It hopes to be able to offer free instruction on courses in physical therapy and also have available a list of accredited institutions which offer graduate and postgraduate instruction. The special committee is now trying to reestablish contact with the medical societies that have not appointed committees and cooperate with the committees that have been appointed. This cooperation will include a more detailed survey of hospitals and institutions practicing physical therapy, promotion of the teaching of physical therapy to graduates and undergraduates in medical schools and hospitals, the making of a survey of such schools to ascertain in writing their curriculum and requirements for admission, number of students graduated each year and whether diplomas are given, securing the cooperation of manufacturers and distributors in an effort to do away with commercial courses, ascertaining the number of physical therapy treatment to the public and under what authority they operate, encouraging the presentation of papers on physical therapy subjects at meetings of state and county

medical societies and at hospital staff meetings, and making sure that physical therapeutic literature and books are obtainable in medical and hospital libraries.

The purpose and achievements of this committee are commendable. The Council on Physical Therapy hopes that more state medical societies will follow the example of the California State Medical Association by establishing special committees on physical therapy with the aim of cooperation with the Council on Physical Therapy in a program intended to lead to fuller appreciation of the importance and use of physical therapy in the treatment of disease. Further reports on the status of physical therapy in other states will be published when available.

VICTOR DIATHERMY APPARATUS ACCEPTABLE

The General Electric X-Ray Corporation of Chicago manufactures the following apparatus, designed to generate high frequency electrical currents for therapeutic purposes:

V2857 Vario Frequency Diathermy Outfit with Auto Condensation Coil and Meter arranged for operation on 115 volt, 60 cycle alternating current. Shipping weight 155 pounds or 70 Kg (fig 1).

V2858 Same as foregoing but for operation on 230 volt, 60 cycle alternating current. Shipping weight 155 pounds or 70 Kg.

V2855 Vario Frequency Diathermy Outfit, without Auto Condensation Coil arranged for operation on 115 volt, 60 cycle alternating current. Shipping weight 150 pounds or 68 Kg.

V2856 Same as foregoing but for operation on 230 volts, 60 cycle alternating current. This apparatus is also obtainable for 25.49 cycles on special order. Shipping weight 150 pounds or 60 Kg.

Several of these units have been investigated in laboratories and clinics acceptable to the Council. The reports indicate that the machines are reliable and satisfactorily constructed. Furthermore, the merchandising policies of the corporation conform with the Official Rules of the Council.

These machines are marketed under the trade name "Vario-Frequency." As interpreted by the firm, high frequency generators equipped with this feature enable the operator of these devices to vary within limits the frequency of the diathermy current generated. The corporation does not claim specific biologic effects for the range of frequencies ordinarily obtained in diathermy or obtained by the selection of various taps. The investigation of the Council confirmed the claim that, by the selection of various taps provided, the frequency of the diathermy current can be varied. The Council regarded the machines as satisfactory generators of

Fig. 1—Victor Vario Frequency Diathermy Machine

the frequency of the diathermy current can be varied. The Council regarded the machines as satisfactory generators of

Fig. 2—Schematic diagram of circuit

high frequency electric current for use in electrosurgery and the practice of physical therapy. Figure 2 is a schematic diagram of the circuit.

The Council declared the apparatus eligible for acceptance and included them in the list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

SOLUBLE BARBITAL (See New and Nonofficial Remedies, 1934, p. 104)

Medinal—A brand of soluble barbitol—U S P. Manufactured by Schering & Glatz Inc. New York. U S patent 780,241 (Jan. 17, 1905 expired) and 879,499 (Feb. 18, 1908 expired). U S trademark 269,753. Medinal Tablets 5 grs. Medinal Suppositories 10 grs.

PROCAINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1934, p. 60)

The following dosage forms have been accepted:

Ampule Solution Procaine Hydrochloride 2% 1 cc. Each cubic centimeter contains procaine hydrochloride U S P 0.02 Gm. (1/50 grain) in aqueous solution.

Prepared by the Cheplin Biological Laboratories Inc. Syracuse, N. Y. No U S patent or trademark.

Ampule Solution Procaine and Epinephrine 3 cc. Each cubic centimeter contains procaine hydrochloride U S P 0.02 Gm. (1/50 grain), epinephrine 0.04 mg. (3/1000 grain) and sodium bisulphite 0.001 Gm. in an aqueous solution containing less than 0.5 per cent of chlorbutanol.

Prepared by the Cheplin Biological Laboratories Inc. Syracuse, N. Y. No U S patent or trademark.

CHINIOFON (See New and Nonofficial Remedies, 1934, p. 138)

Chiniofon-Winthrop—A brand of chiniofon—N N R. Manufactured by the Winthrop Chemical Company Inc. New York. No U S patent or trademark. Tablets Chiniofon Winthrop 0.25 Gm. (4 grains). The tablets are coated with keratin.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING RELATIVELY RECENT DECISIONS FOR THE INFORMATION OF BOTH THE PROFESSION AND MANUFACTURERS.

PAUL NICHOLAS LEECH, Secretary

RECENT REVISIONS OR ELABORATIONS OF THE COUNCIL'S RULES OF INTEREST TO MANUFACTURERS AND THE MEDICAL PROFESSION

1 Scope of N N R

Soaps—The Council considered the question of the eligibility of soaps for inclusion in New and Nonofficial Remedies. It was pointed out that soap is not primarily a medicinal agent nor is it a new and nonofficial remedy, but it is a *borderline* preparation between cosmetics and therapeutic agents. The Council concluded for the present not to consider soap preparations which are employed simply for their detergent effect and for which no unwarranted therapeutic claims are made.

Cosmetics—The Council has reaffirmed its previous decision that cosmetic preparations which are marketed with no special therapeutic claims are outside the scope of the Council's consideration.

The Term 'Open Market'—Under the heading "Substances Described in New and Nonofficial Remedies" (N N R 1934, p. 15) occurs the following statement:

An article will not be accepted or retained unless it is found in the open market under the name of the firm under which it is submitted or accepted.

The Council's attention was directed to some difficulties that had arisen in the interpretation of this provision, which is the result of a recent revision. It was pointed out that, if the interpretation of the phrase "open market" is restricted to drugs found at retail, the Council would probably overlook instances in which shipments of drugs in quantity may go to institutions, eventually to be dispensed, and which are pre-

sumably as much in need of supervision by the Council as drugs sold over the counter. The Council decided that the term "open market" contemplates both the retail and the wholesale dispensing of drugs and directed that the statement quoted be elaborated by addition of the following:

The term open market contemplates both the wholesale and the retail merchandising of drugs.

2 Rule 1—Composition

Labeling of Ampules.—In conformance with the conclusion of a combined contact committee representing the manufacturers of pharmaceuticals, the U S Food and Drug Administration and the American Medical Association, the Council last year adopted the ruling that, in the case of products marketed in ampules, the individual ampule label or unit package thereof must bear the description "— cc size" together with the explanatory statement "Each ampoule contains a sufficient amount to permit withdrawal and administration of — cc." This statement may be made on a separate slip attached to the ampule or ampule package. As the result of experience in the carrying out of this ruling, the Council later held that it should not apply to ampules containing more than one dose and further that in the case of serums and vaccines marketed in syringes the explanatory statement need not contain the word "withdrawal."

Label Declaration of Preservative in Pollen Extracts.—While the Council's rules have always required that manufacturers make known the nature of preservatives used in mixtures, there has been no requirement that these be specifically declared on labels and in advertising. In the recent consideration of a pollen preparation it was brought out that the firm is now using a dextrose-phenol menstruum for the product. It was pointed out that the label declaration of the preservative phenol would be of service to the physician in that it would enable him to determine whether or not there is bacterial contamination when the solution becomes cloudy. There is less difficulty with solutions made up with a preservative and occasionally cloudiness does occur which does not necessarily indicate bacterial contamination. It was therefore decided that the manufacturers of Council-accepted pollen extract preparations be required to declare on labels and in advertising the identity and amount of the preservative contained. It was further required that appropriate revision of labels and advertising be made by Jan 1, 1935.

3 Rule 4—Indirect Advertising

Permanently Affixed Names.—The comments to the Council's rules provide that when the name or initials or other distinctive mark of the article is permanently stamped on the container, on the article itself, or is on the stoppers or seals, the product is in conflict with rule 4. Recently a manufacturer asked permission to imprint the firm name on its uncoated tablets. The firm stated that the various classes of tablets on which it was desired to make such imprint represent over three fourths of the firm's output of uncoated tablets. The Council decided that whereas the use of such permanently affixed name on a single variety of tablets would be an infringement of rule 4, such use when involving all or a greater part of a firm's output does not conflict with the intent of the rule.

4 Rule 6—Unwarranted Therapeutic Claims

Submission of New Therapeutic Claims.—It was brought to the Council's attention that no rule specifically requires that new therapeutic claims made for articles subsequent to the time of their acceptance be submitted to the Council, although it has been held that such new claims should be submitted for review before they appear in advertising copy. In order to make the rule clear on this point the Council adopted the recommendation of its Committee on Rules and Procedure that the comments to rule 6 (N N R 1934 p 19) be revised by insertion after the word "product" (line 6) of the following sentence:

Therapeutic claims made subsequent to the acceptance of an article must be submitted to the Council for review, provided such claims exceed or substantially modify those made at the time of acceptance.

The Use of Films for Advertising.—The Council's attention has been brought to the use of films to advertise medicinal preparations. The Council's Committee on Rules and Pro-

cedure held that such films should be subjected to Council scrutiny so far as they may relate to the rules governing therapeutic claims and lay or professional advertising. While this activity is essentially a form of advertising, the committee pointed out that it is closely pertinent to rule 6 (Unwarranted Therapeutic Claims) and held that the comments on this rule seems to be the appropriate place to provide for the review of such films. The Council directed that the second paragraph under Unwarranted Therapeutic Claims (N N R 1934, p 20) be amplified by addition of the following sentence:

The Council holds that the terms advertising and advertising literature include films and similar devices for informing the public or the profession.

5 Rule 8—Objectionable Names

Coined Names for Salts and Pharmaceutical Preparations.—The Council adopted the following recommendation of its Committee on Rules and Procedure:

1 That coined names for salts be not accepted unless such names indicate both components as for example "Ephedrine Sulphate", the name Ephedrine is acceptable only for the base and

2 That coined names for new substances marketed as pharmaceutical preparations be not accepted unless such names adequately indicate the identity or dosage form of the article for example a new hypnotic Aliphal Powder, and

3 That for the present, this rule be not made retroactive in its application.

In conformance with this action, the Council adopted the following addition to the "Explanatory Comments" on the rule:

Difficulty frequently arises from the application of coined names to salts. For example, a firm introduces the hydrochloride of a synthetic base under the name "Artifisialin". Subsequently the firm decides to introduce the lactate of the same base. If this is called "Artifisialin lactate" the name "Artifisialin" will now mean the base instead of the hydrochloride which is being marketed under that name. In order to avoid this confusion the Council holds that coined names for salts will not be accepted unless such names indicate the components of such salts thus "Artifisialin hydrochloride" the name "Artifisialin" unqualified, is acceptable only for the base. A similar difficulty may arise when a product is marketed first only as a pharmaceutical preparation to which the manufacturer wishes to apply a short coined name, for example, an elixir of a new hypnotic under the name "Aliphal". If later the manufacturer elects to market the substance also in powder form, an entirely new name would become necessary and this would cause confusion both to the profession and to the trade. The Council therefore holds that coined names for new substances marketed as pharmaceutical preparations will not be accepted unless such names indicate the type or dosage form of the preparation thus "Elixir of Aliphal" "Aliphal Powder" not "Aliphal" unqualified.

Names of Barbitol-Amidopyrine Mixtures.—The Council considered the question of creating simple generic names for preparations representing mixtures of barbitol and amidopyrine. Various names were suggested but in the end the Council doubted the desirability of contracted names. Since both ingredients are important and both are subject to idiosyncrasies, the Council held it advisable that the prescriber be definitely reminded of each component. The Secretary was directed to advise manufacturers of accepted barbitol preparations that the Council is prepared to consider (with a view of determining acceptance for N N R) mixtures (in fixed proportions) of barbitals and amidopyrine under such descriptive name as "Tablets (name of barbitol derivative)-Amidopyrine."

The Use of Brand Marks.—The Council's ruling concerning the identification of a firm's products (N N R 1934, p 22, par 2) reads as follows:

In the marketing of unoriginal articles the legitimate interests of the producer are fully served by identifying such products by appending the name or initials of the manufacturer or agent or by the use of a general brand mark. No objection will be made by the Council to the use of such brand marks provided that in no case shall such mark be used as a designation for an individual article.

The Council's attention was directed to certain brand marks that may give rise to unwarranted implications of merit or to other misunderstandings. After ruling on a particular instance, the Council decided that the statement just quoted be further clarified by addition of the following:

Names, initials or brand marks of manufacturers or agents when used to denote proprietorship shall not be of such character as to cause any misunderstanding or confusion as to their significance.

Names for Liver Oils.—The Council's rules provide for recognition of an informative coined name for a preparation that represents a distinct advance over available preparations. In accordance with this the name "Haliver Oil" for halibut

liver oil was recognized by the Council because the introduction of this oil of materially higher vitamin A content constituted a departure from the available cod liver oil. This first step appeared to be of sufficient therapeutic importance to warrant permission of a proprietary name. However, the Council holds that the originality of the departure is naturally restricted to the first step and that the introduction of oils from the livers of other animals does not involve any originality unless some other distinguishing factor is present. When, therefore, a firm asked for recognition of a proprietary name for an oil derived from the livers of mammals, the Council refused such recognition and the firm was informed that an acceptable non-proprietary name would be "Liver Oil Mammalian" followed by the name or initials of the firm.

6 Rule 10—Unscientific Articles

Hypophosphites—For years the Council has held the hypophosphites to be therapeutically worthless. In 1932 the Council accepted an emulsion of cod liver oil on the condition, among others, that the calcium hypophosphite and sodium hypophosphite which the preparation then contained be omitted. Last year the firm informed the Council that complaints had been received from users of the product that the product as marketed became more acid (rancid). The firm felt that this was due to the omission of the hypophosphites and requested permission to restore them to the formula as preservatives. The firm disclaimed any intention of claiming therapeutic effect for the hypophosphites. The Council granted the request on condition that definite statement is made in the advertising for the product that the hypophosphites are added for pharmaceutical purposes only.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
RAYMOND HERTWIG, Secretary

NOT ACCEPTABLE

"HONEY AS A FOOD" ADVERTISING LEAFLET

An advertising leaflet entitled "Honey as a Food," by E. R. Root, editor of *Gleanings in Bee Culture* and president of the A. I. Root Company, Medina, Ohio, was submitted to the Committee on Foods for consideration for acceptance.

This leaflet is largely a hodgepodge of misinformation concerning alleged values for honey. The use of the names of doctors, professors, bacteriologists, departments of health and hospitals gives the leaflet the semblance of an authoritative statement. The titles of the sections indicate the type of information presented.

Honey a Natural Food. Honey an Energy Food. Honey Superior to Sugar as a Sweetener. Why Honey Instead of so much Cane Sugar? Honey in Place of Sugar for Diabetes. The Deadly Parallel of White Sugar and Diabetes. Honey for Diabetes. Honey for Weak Heart. Honey for Athletes. Honey not Injurious to the Teeth like Ordinary Sugar. Honey a Destroyer of Disease Germs. Honey in Automobile Radiators.

The author states

A constituent of no slight importance in honey is lime. Unless care is taken in the selection of foods this important factor in bone building may be neglected.

Honey contributes an insignificant amount of calcium to the diet. It is incorrectly alleged that ordinary cane sugar "taxes the digestive organs" in the statement:

Since it does not require a change in form before assimilation honey unlike cane sugar does not tax the digestive organs. Before sugar can be admitted to the blood it must be in invert form like the sugars in fruits or honey.

A normal person has no difficulty in digesting cane sugar, one of the most readily digestible of foods. Claims alleging superiority of digestibility of honey over cane sugar serve only to mislead. It is further claimed that:

Candy eating, when it comes to be a habit is ruinous to the teeth as well as to the whole body. There is plenty of authority to show that common white sugar (sucrose) eaten in the quantity that it is very injurious to the teeth while honey a natural sweet is not. Among the authorities that may be mentioned that testify that white sugar is injurious to the teeth are Dr. J. C. Turner a distinguished English

dentist Dr. J. S. Wallace. Sir Henry Baldwin the king's dentist Dr. A. C. Jones etc. etc. Some of these, including Dr. Williams, assert that honey is not harmful to the teeth. Any dentist of standing will tell his patients that the candy-eating habit is the most potential cause of the decay of the teeth. This enormous consumption of refined cane sugar is believed to be responsible in large measure for sugar diseases the principal one of which is diabetes. There are some interesting facts that go to show that diabetes keeps pace in this country almost directly with the consumption of cane sugar. Cane sugar is demineralized and therefore not as healthful as the unrefined sugars. But the great abuse of modern civilization is the foolish indulgence in demineralized devitalized foods of all kinds. It is significant therefore that deaths from diabetes keep pace with the per capita consumption of white sugar. Physicians who have made a special study of sugars, especially honey are recommending the natural sweets found in fruits and in honey instead of so much cane sugar.

There is no objection to eating candy as long as the diet in toto contains sufficient of the essential food substances, vitamins, minerals, proteins and certain fats. Candy is not specifically detrimental to the teeth, the incomplete diet however, is detrimental. It has not been shown that the replacement of cane sugar with honey would give greater protection to the teeth. Honey has practically the same limited nutritional values as cane sugar. No authoritative data indicate that cane sugar is specially the cause of diabetes. Although assuming, for the sake of argument, that the excessive use of cane sugar may be related to an apparent increase of diabetes, there is no justification for the implication that the substitution of honey for cane sugar in the American diet would alter the situation. The digestion of cane sugar in the gastro intestinal tract produces invert sugar, the chief ingredient of honey. There is no objection to the use of refined sugars or foods as such. Their excessive use, however, replacing foods furnishing necessary vitamins, minerals and proteins for the body's needs, is detrimental.

An especially deceptive type of claim hazardous to the health of the diabetic patient is:

Davidoff observed that honey was tolerated by the diabetic to whom sugar in any form was a poison. He reported his finding to the medical fraternity. A large number of people suffering from diabetes have been relieved by substituting honey in place of ordinary sugar.

A quotation of Dr. Banting, as presented, is unsupported by scientific evidence.

One cannot help but conclude that in the heating and recrystallization of the natural sugar cane something is altered which leaves the refined product a dangerous foodstuff.

An excerpt from the book "The New Dietetics" of Dr. J. H. Kellogg of Battle Creek Sanitarium implies that cane sugar is harmful and something to be feared but states that honey may be "eaten freely," an unwarranted distinction.

It is quite possible that good results would follow the exchange of at least a considerable part of the cane sugar we consume for honey.

Large quantities (cane sugar) cause acidity and give rise to gastric catarrh and indigestion. Sweet fruits such as raisins and figs, honey and maltose or malt sugar are natural and wholesome sweets and may be eaten freely.

Excessive quantities of honey, cane sugar or any other sugar may be harmful.

A misleading therapeutic claim is

Honey for Weak Heart. The objection to ordinary granulated sugar or practically all of the commercial sugars is that they are irritants; they must be changed by the digestive fluids before they can be absorbed. Large quantities of granulated sugar (sucrose) cause a severe strain upon the pancreas. A continued consumption of such sugar causes a breakdown of this organ often resulting in diabetes, a sugar disease. Doctor Arnold Lorand, author of *Old Age Deferred*, is one of the most eminent medical authorities in all Germany. In the book *Old Age Deferred* he says: "As a most valuable food for overwork of the heart and the general circulation I recommend honey." I consider it unwise to place severe cases of diabetes on a strict diet and I recommend to them the use of fruit sugar (levulose) which is often well utilized and especially in a case of diabetes with heart failure. As the best food for the heart I recommend honey on the basis of the above mentioned observations. It is the best sweet food as it does not cause flatulence and can even prevent it to a certain extent promoting the activity of the bowels. It can easily be added to the five meals a day. I recommend in cases of arteriosclerosis and weak heart. Many more references could be produced to show that honey is a quick and satisfactory restorative for weak hearts.

Honey has no specific value for the morbid conditions referred to as implied.

One of the many examples of the use of high sounding terms for impressively deceiving the credulous follows:

Doctor Paul Luttinger of New York City, Adjunct Pediatric Bronch Hospital Pathologist Bronx Hospital, Chief Pediatric Clinic Bronx Hospital, O. P. D. Lecturer on Diseases of Children at the Flower Hospital.

Medical College Bacteriologist to the Research Laboratory of the New York City Department of Health from 1913 to 1917 and for the last eight years Professor of Bacteriology and Pathology and Director of Laboratories at the First Institute of Pediatrics in the New York Medical Journal and Medical Record for August 2 1922 writes a strong article favoring the use of honey in place of so much cane sugar Among other things he says Honey may be given to children suffering from the most serious diseases except in diabetes and acute inflammatory conditions of the gastro intestinal tract Even in diabetes however small quantities of honey may be given as it is much better tolerated than sugar For the last two years I have been using a jam made from rose leaves and honey exposed to the ultra violet rays of a quartz mercury lamp in cases of rickets and tuberculosis with excellent results

The exposure of honey "to the ultra-violet rays of a quartz-mercury lamp" has no known value for the treatment of rickets and tuberculosis

Ingenuity in the art of deception through implication is shown in the statement

'Honey as a destroyer of Disease Germs Dr W G Sackett bacteriologist of the Colorado Experiment Station Fort Collins Colorado conducted an elaborate series of experiments in which he proved that some of the disease germs that attack human beings die in the presence of honey in a comparatively short time He summarizes by saying The longevity of the typhoid colon group in honey is very limited The prob ability of honey acting as a carrier of typhoid fever dysentery and various diarrheal affections is very slight Dr A P Sturtevant bacteriologist in the Bureau of Entomology Washington D C confirming this says that honey has the peculiar and distinctive property of absorbing moisture from anything that comes in contact with it A certain amount of moisture is necessary to maintain life in all living organisms so when bacteria comes in contact with honey and this vital amount of moisture is withdrawn it dies

Statements of this character for promoting a good food are absurd and ludicrous Honey has no practical value as implied for destroying disease germs inside or outside the body or for preventing disease, infection or the spread of disease

Probably the most enlightening paragraph of the entire leaflet is the closing one suggesting the usefulness of honey as an 'antifreeze' in automobile radiators

This leaflet is an offense to honest advertising and can only discredit the wholesome, popular food it would promote The public is seriously misled by false advertising of the type represented by this leaflet, which cannot therefore be listed among accepted advertising of the Committee on Foods

NOT ACCEPTABLE

LITTLE CROW COCO-WHEATS

THE COCOA COATED CEREAL

The Little Crow Milling Company, Inc., Warsaw, Ind., submitted to the Committee on Foods a mixture of farina and semolina lightly coated with cocoa, with added sodium chloride and flavored with vanilla, called "Little Crow Coco-Wheats, The Cocoa Coated Cereal"

Discussion of Label and Advertising—The name Coco-Wheats unduly emphasizes the cocoa ingredient, implying that cocoa is in major proportion in the product, whereas it is present only as a flavoring Cocoa Flavored Farina is a fitting name Since the added salt and vanilla are not declared, the label implies that the only ingredients are farina and cocoa The product name should be accompanied by the statement "flavored with salt and vanilla" The public is entitled to know all the ingredients of the foods it consumes

The label and advertising contain the following statements

Little Crow Coco-Wheats The Cocoa Coated Cereal contains essential elements necessary for infants growing children or the requirements of adults or invalids The addition of finest quality cocoa gives not only greater food value but a strong appeal to backward appetites Coco Wheats supplies vital energy quickly and easily without burdening digestion Coco Wheats is served regularly in many large hospitals rich in vitamins

This food does not contain *all* the (nutritional) requirements of adults or invalids as stated The chief nutritional or food value is the caloric energy content or fuel energy value and very subordinatedly the wheat protein The claim that it "contains essential elements necessary for invalids and growing children" connotes more important and broader nutritional values than actually possessed Vague claims of this character are misleading and should be replaced by definite statements specifically naming the nutritional or other values to be emphasized The cocoa content does not significantly add to the food value as incorrectly stated The article does not 'supply vital energy any more than do usual foods but merely provides

simple food fuel or caloric energy "Vital energy" implies "life energy" and is misleading by connotation No evidence was furnished indicating that Coco-Wheats is served regularly in many hospitals Vague alleged claims of use by hospitals deceptively ascribe imaginary special nutritional or therapeutic values to the product The advertising should specifically state why the food is recommended or for what purpose The product is not "rich in vitamins" but, to the contrary, is practically devoid of vitamins

The advertising indicates disregard of fact and resorts to vagaries to suggest deceptively greater values than warranted by fact Labels and advertising for foods should simply and specifically name the foods and their ingredients, and define their food values in easily understandable terms, in the interest of public welfare and good business competition

The company was informed of the criticisms and recommendations of the Committee but has not demonstrated willingness to comply This cereal will therefore not be listed among the Committee's accepted foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION

RAYMOND HERTWIG Secretary

KRIM-KO'S FIVE-O CHOCOLATE FLAVORED SWEETENED DILUTED SKIM MILK

Manufacturer—Krim Ko Company, Chicago

Description—Sterilized, chocolate flavored sweetened diluted skim milk containing skim milk, water, sucrose, chocolate and cocoa, tapioca flour, salt and a trace of agar, flavored with imitation vanilla extract

Manufacture—The product is prepared by essentially the same procedure as described for Krim-Ko (THE JOURNAL, June 2, 1934, p 1851)

Analysis (submitted by manufacturer) —

	per cent
Moisture	85.3
Ash	0.6
Fat (ether extract)	0.6
Protein (N x 6.25)	1.6
*Reducing sugars as invert sugar	4.5
*Reducing sugars as lactose	1.1
Sucrose (copper reduction method)	4.2
Crude fiber	0.1
Carbohydrates other than crude fiber (by difference)	11.8
*Caffeine and theobromine	0.02

* Calculated from composition of Krim Ko's Five O Drink Base (THE JOURNAL June 2 1934 p 1851) or skim milk

Calories—0.6 per gram 17 per ounce

(1) CASSEL'S EVAPORATED MILK

(2) PICKWICK BRAND EVAPORATED UNSWEETENED STERILIZED MILK

Distributors—(1) Cassel's Stores, Reading, Pa

(2) Kansas City Wholesale Grocery Co, Kansas City, Mo

Packer—The Page Milk Company, Merrill, Wis

Description—Canned unsweetened sterilized evaporated milk, the same as Page Brand Evaporated Milk (Sterilized, Unsweetened), THE JOURNAL, May 30, 1931, page 1872

COTTAGE EVAPORATED MILK

FOX RIVER EVAPORATED MILK

PETER PAN EVAPORATED MILK

Manufacturer—Libby, McNeill & Libby Chicago

Description—Unsweetened evaporated milks

Manufacture—The same as Libby's Sterilized Unsweetened Evaporated Milk (THE JOURNAL, June 13 1931, p 2037)

Claims of Manufacturer—See announcement on the advertising of the Evaporated Milk Association (THE JOURNAL, Dec. 19 1931, p 1890)

SATURDAY, JUNE 23, 1934

THE CLEVELAND SESSION

One of the greatest medical assemblages ever held in this or any other country was the annual session of the American Medical Association in Cleveland last week. The attendance was the largest ever recorded in a city the size of Cleveland. On only three previous occasions, even in larger cities, has the attendance exceeded that of this gathering. More significant than the attendance, however, were the nature and the spirit of the occasion, the interest shown, and the significance of the actions taken by the House of Delegates.

Probably the most important of the resolutions adopted by the House of Delegates were those concerning the principles that are to guide the medical profession in its consideration of new forms of medical practice and the one expressing the unanimous belief of the House of Delegates that only the American Medical Association is entitled to voice the opinion of organized medicine on these topics. The House of Delegates also took many other important actions, which will be regularly considered in *THE JOURNAL* and which will be made available in the complete report of the proceedings of the House of Delegates, of which publication will begin in this issue.

The scientific sections of the Association were extremely well attended and the discussions lively. Moreover, the General Scientific Meetings attracted large numbers of interested listeners and established the value of such occasions as a form of postgraduate instruction.

The Scientific Exhibit at the Cleveland session was remarkable for its size, its scope, its instructive value and the beauty of presentation. With increasing experience those who participate in the Scientific Exhibit have developed methods of graphic portrayal that make the acquisition of new information a delight. The framing, the illumination and the color of the exhibits aroused general admiration. The special exhibits drew multitudes of interested physicians, and a large number of the papers read in the sections were supplemented by exhibitions of materials extending the knowledge conveyed by the manuscript itself.

The technical exhibits brought together the largest number and variety of industrial organizations catering to the medical profession that have participated in such exhibitions. The exhibitors expressed unanimous commendation of the arrangements made for them and of the manner in which physicians in attendance availed themselves of the opportunities to improve methods of practice by employment of the facilities made available. Furthermore, many exhibitors voluntarily indicated that the returns had been greater in proportion to the outlay than ever before. This may be taken as a sign of the improved economic trend at this time.

The physicians of Cleveland and the state of Ohio surpassed themselves in providing suitable entertainment. The golf tournament of the American Medical Golfing Association included 185 players and the annual banquet was a memorable event. The dinners given by Ohio physicians to the officers and to the House of Delegates of the American Medical Association were not only congenial but also convivial. Many leading physicians held open house during the week. The annual reception for the President was held in one of the most delightful of halls and the music and color of the occasion were brilliant.

As a result, no doubt, of the increasing interest of the public in medical advancement and medical affairs, the press of the country as well as the radio took special interest in the Cleveland session. National broadcasts were made from the meeting as well as many daily local broadcasts. Special correspondents were sent from newspapers in Chicago, St. Louis and New York, and all the great press syndicates were represented by scientific writers who have been attending meetings of the Association for some years.

The Cleveland session will pass into history as a new peak in scientific gatherings.

POLIOMYELITIS IN CALIFORNIA

With the news spreading widely over the United States that there is an increase in the incidence of anterior poliomyelitis in the Los Angeles area, physicians everywhere are being besieged with questions as to whether or not it is safe to travel into that district and as to whether or not the incidence is sufficiently great to be termed epidemic. The number of cases is well beyond the average incidence of infantile paralysis in the community concerned and is therefore of epidemic proportions. No one can say just when the epidemic will reach its peak. The factors concerning the duration of such epidemics are not well established. Some epidemics in southern California, according to information received from the U. S. Public Health Service, seem to extend over longer periods than elsewhere, and the curves have flatter tops than those of other similar areas. This does not necessarily mean a larger number of cases per hundred thousand of population.

The incidence of poliomyelitis is higher than normal for Los Angeles or for any other California district, and it is not considered safe to send a small child into the vicinity. The danger, of course, is small in comparison with the danger from much more contagious conditions, but the danger is definite and should not be assumed if it is avoidable. A child under six years of age falls within the most susceptible age group and for this reason would be subjected to a special hazard if taken from a noninfected area into an infected area. It is, moreover, especially difficult to protect a child against contact with infantile paralysis, since the disease seems to be distributed by carriers, as are also scarlet fever and diphtheria, so that the child might become infected from a person who is apparently well. Epidemiology establishes the fact that infantile paralysis, like epidemic encephalitis, clears up with the coming of cold weather. In the Los Angeles area the first really cool weather may not be expected until November or December.

Considerable agitation is apparent among parents as well as among physicians for mass immunization of the apparently well child, not only in the Los Angeles area but also in San Francisco and in adjacent cities. Whole blood or convalescent serum is suggested for prophylaxis. A survey of the available evidence indicates that neither of these methods has been used to a sufficient extent in well controlled experiments to provide data of value, either in favor of or against its efficiency. In measles, convalescent serum seems to have value, and, with the certain knowledge that antiviral substances for poliomyelitis exist in the serums of adults and of recovered cases, the prophylactic use would seem to be rational and might be given a trial in children who are unavoidably exposed to the epidemic area. However, the period during which such protection might continue from a single injection is not known. If such experiments are made, records should be accurately kept, as the information will be of exceeding value in determining future practice.

THE FUEL OF MUSCULAR WORK

What is the source of the energy transformed in the work of the muscles? The source of the mechanical work of the contractile tissues must be from metabolism. It has long been demonstrated that mechanical work may have little or no effect on protein metabolism. As Graham Lusk, an expert in this field of research, expressed the situation, protein itself may be resolved into dextrose and beta-oxybutyric acid, so that the question of the source of muscular power reduces itself to the consideration of behavior of metabolites of carbohydrate or of fat.¹ Every one admits that carbohydrate usually functions as the fuel of muscular work. Some investigators stoutly main-

tain that it is the sole immediate source of the energy of contraction and that fat can function in this respect only after it has been converted somehow into sugar. As Gemmill² has pointed out, evidence for or against the utilization of fat during muscular exercise in man has been obtained from observations of the respiratory quotient, the blood fats and the acetone substances. The respiratory quotient has been most extensively studied.

Rapport³ reviewed the literature on the respiratory quotient of the exercising animal. He concluded that the evidence from the respiratory quotient did not justify the belief that carbohydrate alone was oxidized to supply the energy for muscular activity. The interpretation of the significance of the respiratory quotient is difficult at best, so that, according to Gemmill, since there are two ways of interpreting the respiratory quotient, the evidence obtained from this quotient in man during exercise becomes less valid for determining a particular type of metabolism.

At the Johns Hopkins School of Medicine, Gemmill² has made a study of the total acetone bodies in the blood of three persons before and after exercise with the subjects on normal and low carbohydrate diets. He mentions the commonly accepted view that the acetone substances in the blood of men on low carbohydrate diets, in starvation and in diabetes come from the incomplete combustion of fat. Therefore, an increase in these compounds resulting from work suggests that there has been an increase in the amount of fat broken down during and after muscular work to supply the energy for the exercise. The exact mechanism for the utilization of this fat cannot be obtained from this type of experimentation, except that it does give suggestive evidence that the fat is oxidized directly and not converted into carbohydrate. Significant changes were not observed following exercise with the persons on normal diets. On low carbohydrate diets, with a general elevation of the acetone substances, a further increase was found after work. The maximal rise in each case was observed two hours after exercise. These experiments suggest that fat is used as such to supply the energy for muscular contraction in man.

Current Comment

JAMES S MCLESTER, PRESIDENT-ELECT

The President-Elect of the American Medical Association, Dr James Somerville Mc Lester, comes to office with a distinguished career of service to organized medicine. He was born in Tuscaloosa, Ala., Jan 25, 1877. He received his A B degree from the University of Alabama in 1896 and the M D degree from the University of Virginia Department of Medicine in 1899. Then followed postgraduate work at

1 Lusk, Graham. *The Elements of the Science of Nutrition*. Philadelphia: W. B. Saunders Company, 1928.

2 Gemmill, C. L. *The Effect of Exercise on the Acetone Bodies in the Blood of Man on Low Carbohydrate Diet*. *Am J Physiol* 108: 55 (April 1) 1934.

3 Rapport, David. *Physiol Rev* 10: 349 (July) 1930.

Göttingen and Freiburg in 1901 and 1902. He became professor of pathology and later professor of medicine in the Birmingham Medical College, holding this position from 1902 till 1912. This period also included postgraduate study in Berlin and Munich during 1907 and 1908. In the World War he acted as major and chief of medicine in the Base Hospital at Camp Sheridan and was promoted to lieutenant colonel in the American Expeditionary Forces, becoming commanding officer of Evacuation Hospital 20 in 1918. During this time he was a consultant in the medical service. In 1919, following the World War, he became professor of medicine in the University of Alabama School of Medicine. The special interest of Dr. McLester has been nutrition. He is the author of many articles on this subject and of books entitled "Nutrition and Diet in Health and Disease" and "The Diagnosis and Treatment of Disorders of Metabolism." He contributed the chapter on the mediastinum in the Oxford System of Medicine and the chapter on syphilis in Cecil's "Textbook of the Practice of Medicine." Dr. McLester was chairman of the Section on Practice of Medicine at the annual session of the American Medical Association in 1920. He served as a member of the House of Delegates from the Section on Practice of Medicine in 1921 and from 1929 to 1933 inclusive. He is a member of the board of regents in the American College of Physicians and also a member of many other scientific medical organizations. In 1929 he became a member of the Council on Medical Education and Hospitals of the American Medical Association, on which he has served continuously since that date. He has been also since 1933 a member of the Committee on Foods of the American Medical Association. Thus, recognition has been given to his learning and leadership. He is a genial and friendly man. In the address that he made to the House of Delegates following his election he expressed his earnest adherence to the principles that must guide the medical profession in its relationship to present economic trends. Through his election the great membership of the American Medical Association in the southern half of our country is again honored.

JAMES S. McLESTER, M.D.
PRESIDENT ELECT OF THE AMERICAN MEDICAL ASSOCIATION

EPINEPHRINE AND THE UTILIZATION OF SUGAR

Although at present there is evidence that carbohydrate metabolism is influenced to a greater or less degree by the activity of the pituitary, the thyroid, the suprarenal, and the insular tissue of the pancreas, far more is known of the activity of epinephrine and of insulin in this respect than of the other hormones. No sooner was the mode of action of insulin determined than it became plain to physiologists that there exists an antagonism between this substance and epinephrine. The two hormones were contrasted with

respect to their influence on blood sugar and on glycogen in the liver. It was shown that an increase in the output of epinephrine occurred after the administration of insulin. Largely through the work of the Coris¹ on epinephrine and glycogen in the liver, the point of view has been emphasized that to a large extent this hormone and insulin exert their antagonistic activity extrahepatically, i. e., in the peripheral tissues. The logical deduction from this conclusion is that epinephrine opposes the utilization of carbohydrate in the tissue. However, a recent study by Soskin, Priest and Schutz² throws some doubt on the validity of this view. Making careful measurements of water exchange, blood sugar and volume of blood flow to an isolated mass of muscle tissue, these investigators demonstrated not only that the retention of sugar was not decreased by simultaneous or separate administration of epinephrine but that it was increased over

that observed when sugar alone was injected. Furthermore, the output of lactic acid from the muscle accounted for less than half of the retained sugar, a fact that likewise runs contrary to the current conception. In view of the growing interest in the part played by the endocrine glands in metabolism in general, it would appear that further studies in this field are necessary with careful attention to such variables as differences in species of test animal, in sex, in age, and in time interval after administration of the hormone.

PROCEEDINGS OF THE CLEVELAND SESSION

MINUTES OF THE EIGHTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT CLEVELAND, JUNE 11 15, 1934

HOUSE OF DELEGATES

First Meeting—Monday Morning, June 11

The House of Delegates convened in the Ball Room of the Hotel Statler and was called to order at 10 a. m. by the Speaker, Dr. F. C. Warnshuis.

Preliminary Report of the Reference Committee on Credentials

A preliminary report of the Reference Committee on Credentials was submitted by the chairman, Dr. J. D. Brook, Michigan, who reported that 102 delegates with proper credentials had registered.

The Speaker, not hearing any objections, declared that the preliminary report of the Reference Committee on Credentials would be accepted.

Dr. J. Newton Hunsberger, Pennsylvania, moved that the House dispense with the roll call. The motion was seconded by Dr. H. B. Everett, Tennessee, and carried.

Adoption of Minutes of Milwaukee Session

The Secretary stated that the minutes of the Milwaukee session of the Association had been printed and put into the hands of all members of the House of Delegates, and that no corrections or amendments had been received, but that a typographic error appeared in the report of the Secretary concerning the number of members reported to the House of Delegates last year. There should have been one thousand more in the official report than was indicated by the figures that were presented.

Dr. H. B. Everett, Tennessee, moved that the minutes of the Milwaukee annual session with the correction indicated by the Secretary, be adopted. The motion was seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried.

The Vice Speaker, Dr. Nathan B. Van Eppen, New York, took the chair while the Speaker read his address, which was referred to the Reference Committee on Reports of Officers.

Address of the Speaker, Dr. F. C. Warnshuis

Members of the House of Delegates

The will of this House of Delegates, expressed through your suffrage, permits me to preside during this annual session. For this renewed expression of your confidence, I am at a loss for terms adequate to the expression of my gratitude. I shall seek to merit your confidence by discharging my duties in a manner characterized by consideration and fairness to every delegate. I am dependent on your assistance to expedite the business that is presented.

This House is the supreme legislative body of our Association. As delegates you are the representatives of your state organization and their members. On you rests full responsibility for action that may be recorded and for the policies and directions that may be affirmed. Whatever may be the national problems of this federation and of its members the action that will accomplish their solution must be formulated by you who speak and act for the members of the Association's constituent units. They rightly look and appeal to you to conserve and enhance their collective and individual interests.

The cry today in all avenues of life is for intelligent achieving leadership. The responsibility for leadership in medicine and our medical relations to the public and to government rests

with this House of Delegates. I commit no violence to facts in stating that if, in these days of radical changes in governmental administration and increasing demands of society, our professional interests are subsidized and we surrender our existent relationship to society, the fault descends in a large measure on this House for having failed to mobilize all our resources to obstruct such an untoward condition and for having failed to undertake the defeat of those who seek to invade our field for the control of our professional services. I have stressed this at previous sessions. I do so again because of a deeper realization that grave changes in medical practice are being proposed and advanced.

REFERENCE COMMITTEES

At the close of the Milwaukee session I was concerned over the fact that by reason of the extended hearings before Reference Committees there was little or no discussion on the floor before a vote on a report, a resolution or a motion was recorded. A delegates report in a state journal conveyed the impression that 'Machinery was well greased and the steam roller working.' Your Speaker desires to correct such a wrong impression.

The procedures of the House prescribe that all reports and resolutions shall be referred to proper Reference Committees. Reference Committees shall hold hearings at which any delegate may appear and discuss a report or resolution. At these hearings, mooted points are clarified and dependable information imparted. The Reference Committee formulates its recommendations, which are presented at a session of this House for adoption. Should any delegate be not in accord with the Reference Committee's report, the opportunity is given him to present his views before a vote is taken. If there is no discussion when the Reference Committee's report is presented, it is assumed that delegates have attended the hearings and concur in the report.

These are not "machine" or "steam roller" tactics. They have been formulated by reason of past experiences in order to enable this House to be expeditious in disposing of the large volume of business that arises annually. There is no gag rule. Every delegate has the right to and will be given the floor to ask a question or record his views on any question that is before the House for consideration.

Reference Committee hearings are announced and posted. Your Speaker urges that delegates appear before these committees for discussion and inquiry.

Your Speaker further recommends that chairmen of Reference Committees might well offer comments on the points raised during the hearings when presenting those portions of their reports dealing with major problems or policies of the Association.

Your Speaker also recommends that consideration be given to the desirability of requesting the Association's Secretary to supply certain Reference Committees with a competent stenographer to take the minutes of a hearing and to whom the chairman can dictate his report. This would relieve chairmen of exacting burdens and conserve their time.

In designating delegates to serve on Reference Committees, your Speaker sincerely endeavors to give just representation to every state. Consideration is also given to the representation that a state has on councils, bureaus and the Board of Trustees.

CREATION OF COMMITTEES

Your Speaker recommends that the By-Laws be amended so as to abolish the Committee on Rules and Order of Business. There has been no necessity for this committee during the past ten years.

The recommendation is made that suitable amendments be adopted to create a Reference Committee on Medical Economics and one on Nominations, the Committee on Nominations to be empowered by a By-Law to nominate three Fellows for the office of President-Elect and three to succeed those trustees whose terms expire, and to make its report at the Tuesday session of the House of Delegates. Additional nominations may of course be made from the floor at the time of election.

ENCOURAGEMENT TO VISITORS

Your Speaker has taken the liberty to suggest to your Secretary that announcement be made in the BULLETIN, THE JOURNAL and the program that sessions of the House of Delegates are open to Fellows and to urge them to attend your deliberations. Many Fellows are under the impression that you sit in closed sessions. On many occasions, Fellows have stated that they wished they could attend your sessions and were greatly surprised when informed that they are more than welcome.

A clearer understanding of organizational problems and activities will result if Fellows become more intimately familiar with the functionings of their House of Delegates. To that end the suggestion is made to encourage attendance by those whom you represent and if need be that the provision for the accommodation of visiting observers be enlarged.

DECEASED MEMBERS

And now, conforming to your action, it becomes my duty to request you to pause to pay tribute to those Fellows who have served in this House and whose life's activities ended during the past year. As I announce their names there will come to each of you some thought some memory related to their services and your association with them. These memories, not transmissible in words, record our enduring tribute.

With a spirit of reverence and memory I now officially record in our records the departure from life of the following Fellows who have served in this House: Lewis H. Adler Jr., Pennsylvania; W. F. Bacon, Pennsylvania; William R. Bathurst, Arkansas; I. C. Chase, Texas; A. L. Chute, Massachusetts; LeRoy Crummer, Nebraska; John S. Davis, Virginia; A. D. Dunn, Nebraska; C. F. Eikenbary, Washington; E. F. Howard, Mississippi; John Edward Lane, Connecticut; Edmund D. Martin, Louisiana; Miles F. Porter, Indiana; George L. Richards, Massachusetts; J. F. Schamberg, Pennsylvania; W. Blair Stewart, New Jersey; D. E. Sullivan, New Hampshire; Claude A. Thompson, Oklahoma; and George B. Young, U. S. Public Health Service.

Reference Committees

The Speaker resumed the chair and appointed the following reference committees:

SECTIONS AND SECTION WORK

Isaac Abt, Chairman
W. R. Steiner
C. W. Roberts

Address of President Dean Lewis

The Speaker presented the President, Dr. Dean Lewis, Baltimore, who delivered the following address which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker and Members of the House of Delegates

It seems almost needless, perhaps rather presumptuous, on my part to express my appreciation of the honor that you conferred on me two years ago when you made me President-Elect of the American Medical Association in New Orleans. One must accept such an honor with humility for one must realize that one cannot discharge efficiently the duties that one assumes and must be called on frequently to make decisions that will not be approved.

During these two years the educational opportunity has been great, for I have had the privilege of attending many national, state and county gatherings. I have never had greater pride in the medical fraternity, for they have gladly assumed the responsibilities which they have been forced to meet during the depression. They have assumed these without complaint, and it is without any attempt at patronizing to say that I have known of no organization, either lay or professional that has rendered such service without complaint. The health of the people has been maintained at a high level. Whether or not the profession is to be given entire credit for this may be a matter of dispute, for it seems that the wind is always tempered to the shorn lamb, for statistics which have been gathered for a number of years have shown that the mortality and morbidity during periods of depression are always low. Social workers apparently are not fully conversant with these facts for there is a tendency on their part to credit this state of health to their unremitting, untiring and self-sacrificing efforts to ameliorate suffering and prolong life, little realizing that Providence works in strange and wondrous ways.

These are changing times, however, and the medical profession has been accused from time to time of not keeping up with the social and economic advances. Our severest critics seem to fail to realize that at any and all times the medical profession has always been the vanguard of the troops which

seek to prevent the development of disease and to care for it when it has once developed. The medical profession has no apologies or excuses to make, for cities could not have survived epidemics, international trade routes could not have been established and the span of life would not have been long enough to justify the pangs of labor. It is sometimes a wonder to me why contraceptive measures were not discussed and introduced years ago when the span of life was so short that the futility of birth must have been frequently discussed.

During the past year I have visited many societies and I find that the profession is troubled. They should realize that they provide the essential part of the care, and without their untiring effort and sacrificing service there would be no medicine, for medical knowledge demands the longest and most technical training of any profession. There would be no paths to follow and we would be lost on the unlighted, uncharted path of ignorance.

Society has been urged to place restrictions on medical practice on the solicitations and frequently the demands of the medical profession. The state in this country which has probably the best medical practice act had a wise governor who was sympathetic with the medical profession and had enough wisdom to select a committee of reputable physicians who wrote an act which he accepted without revision or reservation. This act is in strange contrast to that operative in many states, in which the politicians or laymen have tried to determine for a highly technical profession who should be qualified and how, notwithstanding the fact that fads, fanatics, quacks and cults flourish and propagate their kind in such states.

We should be concerned today with the quality of medical care. Cheap medicine is often the most expensive, and what is called expensive is often the cheapest, for through the quality are attained the objects of medical practice—decrease in mortality, lessening of morbidity and shortening of the period of disability.

One of the heaviest duties now resting on the medical profession is to raise and maintain the quality. If the quality of medical care is to be high, we must have vision and exercise judgment at the beginning, and when I say beginning, I mean when the student is admitted to the medical school. Character should have a higher assessed value than marks alone. The matriculation fee should not be so high that only the children of the well-to-do can enter, neither should it be so low that all may enter.

The quality of medicine is largely determined during the four years of the medical course but must be maintained by wise planning afterward. As I have stated before, I believe that there should be more opportunities for doctors who do not specialize. On leaving the medical schools not infrequently these men never have an opportunity to take patients to the hospitals or to associate with men whom they admired, and they are denied the chance to study gross pathology, which still remains the foundation stone of medicine. The greatest clinicians have had a sound pathologic training and when they examine and study a case they always have memories of a case which they have seen before. The best diagnoses are made on correlated clinical and pathologic observations. To furnish the material with diagnosis, verified by operation or autopsy, is one of the hardest tasks in maintaining the quality of medical care and to the solution of which we should give most serious attention.

A relatively small percentage of doctors attend medical meetings. In order to keep these doctors abreast of the newer ideas, graduate courses of instruction should be given. I was in Idaho last September and the members of the state medical society requested that some of the scientific assembly be sent to them or that doctors be sent from the central office to instruct them in the latest diagnostic procedures. Such attempts to give courses have been undertaken by a large number of medical societies and I have been particularly impressed by the plan of the Medical Society of the State of Pennsylvania, which has been supported so enthusiastically and successfully by its president, Dr. Guthrie. I believe that in the not too distant future a study of the possibilities of such graduate instruction should be undertaken by a committee of this House or by the Council on Medical Education and Hospitals which already has about all the problems that it can successfully handle.

We must preserve the idea that medicine is a profession and not a business, if we are to maintain quality. We must all concede that any one practicing medicine should be able to make a living and I am sorry to say that not infrequently the higher the ideal and the squarer the methods, the less the living.

The medical profession requires the good will and respect of the people. I know of nothing that makes people more suspicious of those engaged in the practice of medicine than the expert witness. Lay people must think that medicine does not even approach an exact science, when two men of equal distinction in medicine will give diametrically opposite statements to questions that are asked at a trial.

Members of the bar realize the futility of much expert testimony, and I would like to see the bar association approached by a committee appointed by the House of Delegates to see whether some method of procedure could be devised by which the expert witness could be eliminated. A reference board, appointed by some competent authority or commission, would probably be most satisfactory, for it could examine in camera the testimony and the documents and hand down the decision, thus avoiding the amazement concerning the conflicting statements of equally capable men.

If the quality of medicine is to be raised, control of methods that are practiced must be strictly and carefully applied. Hasty publication should be discouraged. Publication should be based on accumulated knowledge.

There are two disturbing factors in medicine. First, many doctors and lay people condone advertising. Lay people should realize that advertising in medicine is pernicious, for advertising may wilfully deceive. Commercialism and advertising are among the most demoralizing things in medicine.

As a result of the depression, doctors have had a bad time financially and they may easily be exploited by lay people, both in hospital and in health insurance. The fate of the people as regards medicine will be determined in the ward, the home and the research laboratory.

I look with confidence to the members of the House of Delegates for the solution of the many problems that confront the medical profession. Those questions should be settled by the critical analysis of the facts and data presented and not influenced by passion or the emotions which the problems of the sick so often arouse.

We should remember that it is easy to say that the people are not getting sufficient medical care, but how shall it be provided? Those who practice medicine are always being told how to do it, but those who criticize them have usually had no experience in doing it and couldn't do it at all if called on to do so. We have the right to be proud of our achievements and we can best meet every challenge directed at us by carrying on without fear and with vision.

Address of President-Elect Walter L. Bierring

The Speaker presented the President-Elect, Dr. Walter L. Bierring, Des Moines, Iowa, who presented the following address, which was referred to the Reference Committee on Reports of Officers.

Mr. Speaker and Members of the House of Delegates

During my training year as President-Elect, I have been more and more impressed with the basic spirit of democracy that governs our association. With its ever widening influence, scientific and professional the sovereign right of the individual member still reigns supreme, and this representative body, the House of Delegates, continues as the arbiter of the destiny and policies of organized medicine in America.

It needs no words of mine to say that this will be a historic session, because you are called on to consider medical problems such as have not been encountered before.

There are those without our Association who would speak with authority and much concern of our welfare regarding the solving of these problems. While we gladly listen for guidance from every available source we are confident and deeply conscious of our ability to put our own house in order.

With the evolution in technology, the development of industry and the political economic changes, modern society has come to expect a new order of medical service, different from that demanded a generation ago.

In all time medical practice has influenced and gone hand in hand with the advancement of medical education. In this changing order you cannot therefore disassociate the one from the other, and with far sighted wisdom you have already instituted through the Council on Medical Education and Hospitals a resurvey of all the medical schools of this country. No doubt this action was determined as the result of careful actuarial and factual studies, which tell but the one story—that each year more physicians are being graduated than present society can adequately support.

The time has arrived when this association must recognize its duty to the future welfare of American medicine and attack this problem with all the facilities at its command.

What changes such a resurvey may portend in the present scheme of medical education cannot be foretold but that it will require courage of a high order to mold and influence the educational forces to meet this challenge no one will deny. It should therefore enlist your fullest cooperation and support toward furthering the work of the Council during the coming year.

Your second great problem is concerned with the changing order of medical practice. Well meaning nonmedical advisers have brought to you a variety of artificial remedial plans that are supposed to solve every phase of the problem. We well know that no single "rule of thumb" proposal or method will provide the remedy. The rendering of efficient and complete medical service is still largely governed by the individualistic relation of physician to patient. Furthermore, the practice of medicine is a profession and not a business or a trade.

It is also well recognized that the practice of medicine in the crowded areas of New England and along the Atlantic seaboard is far different from that required in the rural and agricultural sections of the Mississippi Valley. Likewise the activities of the medical practitioner in the Southern states are not the same as those in the wide open spaces of the Dakotas and other Western states.

This association is indeed fortunate in having its Bureau of Medical Economics under the direction of Dr. Leland, who by personal contact has familiarized himself with the problems of medical practice throughout the length and breadth of the land and is able to present to the House of Delegates a very comprehensive picture of existing conditions. When these are further related to his sound conceptions of economic philosophy, they should be a distinct and valuable aid in your labors.

Again through the medium of a great journal and a wide awake editor and general secretary, you have been kept constantly conversant with the problems that concern the individual member and practitioner in this country.

It is sad to relate, that mighty forces have been at work to sow the seeds of discontent in the ranks of organized medicine and to destroy the faith in that leadership which is based on the sacred traditions of sacrifice and devotion to the idealism of medical service.

Would that I could bring to you the full force of the dominant words contained in the presidential address presented recently before two state medical societies, both general practitioners from the plains country, in their ringing appeal, "Stand by the American Medical Association and all will be well."

From all over this broad land the doctor looks to you, members of the House of Delegates, in fullest faith and confidence, not to solve the problem all in a day, but in your wisdom and in the spirit of unity and solidarity to point the way for each to follow gladly.

Out of the land of drought, which has tried the very souls of men, they come with the simple prayer "Give us but a little rain and we will carry on stronger than before."

REPORTS OF OFFICERS

Report of the Secretary

Dr. Olin West then presented his report as Secretary, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary.

Report of Reference Committee on Credentials

Dr. J. D. Brook, Chairman, moved that Dr. Walter Schulte be seated as delegate from Utah, since neither the delegate nor

the alternate from that state could be present. The motion was seconded by Dr. Mather Pfeifferberger, Illinois, and carried.

Report of the Board of Trustees

Dr. J. H. J. Upham, Chairman, presented the report of the Board of Trustees, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary, with the following exceptions. The portion dealing with the Bureau of Legal Medicine and Legislation was referred to the Reference Committee on Legislation and Public Relations, that dealing with the Bureau of Health and Public Instruction was referred to the Reference Committee on Hygiene and Public Health, and that dealing with the Bureau of Medical Economics was referred to the Reference Committee on Medical Economics.

Report of the Judicial Council

Dr. George E. Follansbee, Chairman, presented the report of the Judicial Council, which was referred to the Reference Committee on Reports of Officers.

Report of the Council on Medical Education and Hospitals

General Merritt W. Ireland, Washington, D. C., presented the report of the Council on Medical Education and Hospitals, which was referred to the Reference Committee on Medical Education.

Report of the Council on Scientific Assembly

Dr. Frank H. Lahey, Chairman, presented the report of the Council on Scientific Assembly, which was referred to the Reference Committee on Sections and Section Work.

Report of the Committee on Legislative Activities

Dr. E. H. Cary, Chairman, presented the following report of the Committee on Legislative Activities, which was referred to the Reference Committee on Legislation and Public Relations.

Mr. Speaker and Members of the House of Delegates

Your Committee on Legislative Activities has been consistently engaged in defending the position of the American Medical Association as formulated by this distinguished body in previous sessions. For the sake of brevity we will discuss only veterans' legislation and call your attention to the report of the Board of Trustees, which recounts some of the other work of this committee.

You recall that during the preceding national administration the medical profession opposed the continued building of veterans' hospitals which were to be used for the care of veterans who were not disabled during the World War.

In 1931 your committee with Dr. C. B. Wright as chairman, met in Washington. At this time, in company with Drs. West, Woodward, Shoulders, Johnson and Meyerding and representatives of the American Hospital Association, we made known the medical point of view to the leaders of the American Legion in Washington, to the officials of the Veterans' Bureau and to members of the national Congress. We conceded the need of veterans' hospitals to care for nervous and mental diseases and did not oppose government hospitals for the care of veterans with advanced tuberculosis.

Later Dr. W. C. Woodward and I, in cooperation with representatives of the American Hospital Association appeared before a special joint committee appointed by both houses of Congress and presented many facts concerning the medical profession and its relation to hospitalization, particularly stressing the ultimate effect which an increased hospital construction program would have on our profession.

From our contacts, we came to believe that influences were being developed which would successfully oppose any plan that required the government to continue building hospitals and broadening hospital gratuities to an ever increasing number of veterans without service disabilities. We were particularly insistent that those financially able to care for themselves should be treated at home by their home physicians. Attention was called to the abuse of the hospitalization privilege by the financially independent veteran, who was frequently transported long distances at governmental expense and paid approximately \$85 monthly while in the hospital rendering it very difficult

for the doctor to cure him. Attention of the committee was also directed to the demoralizing effect on the recipient and the welfare of the medical service in a locality this medical service being made more difficult to sustain, and the withdrawal of this support from the medical service in a given community thereby affecting seriously the future health and happiness of large groups of our citizens.

The present administration publicly expressed many views on this subject which were in harmony with the principles adopted by the members of this House of Delegates. The administration evidently recognized that there had been no definite policy established relating to veterans of the late war and that many abuses were the outgrowth of haphazard legislation and Veterans' Bureau regulations.

The need of a balanced budget made necessary an economy program that included a definite policy regarding veterans. We were greatly comforted to find that the present administration supported by the director of the Veterans' Bureau, contemplated no further building of hospitals and outlined a policy which, as stated before, we found in harmony with our views.

In February 1934 the chairman of your Legislative Committee, with the two other members Drs C B Wright and F S Crockett, met Drs Olin West and W C Woodward in Washington to oppose the Reed amendment, which comprised the four-point program of the American Legion. We were particularly interested in the second point of the Legion program which related to hospitalization and which, as written, would have required only a written statement from the veteran that he was financially unable to pay for needed care. We could see that if the law permitted an unsupported statement it might lead to multiplied abuse of hospital and transportation privileges.

Your committee was in Washington for four days, making many contacts, broadening our acquaintance among members of both congressional houses, and developing friendships here and there which we hoped would be useful in preventing legislation not in the interest of the people and detrimental to the medical profession.

Unfortunately, some weeks following our activity in Washington, House of Representatives Bill 6663, the Independent Offices Appropriation Bill was amended combining two issues, one of which concerned the veterans. This readily became a political measure of profound significance and it was not long until it became a law (March 28, 1934) after having been passed by the House of Representatives and the Senate over the President's veto.

Section 29 of the law reads as follows

Section 29. Section 6 of Public Law Number 2 Seventy-third Congress as amended by Public Law Numbered 78 Seventy-third Congress is hereby amended by adding hereto the following proviso:

Provided that any veteran of any war who was not dishonorably discharged suffering from disability disease or defect who is in need of hospitalization or domiciliary care and is unable to defray the necessary expense therefor (including transportation to and from Veterans Administration facility) shall be furnished necessary hospitalization or domiciliary care (including transportation) in any Veterans Administration Facility within the limitations existing in such facilities irrespective of whether the disability disease or defect was due to service. The statement under oath of the applicant on such form as may be prescribed by the Administrator of Veterans Affairs shall be accepted as sufficient evidence of inability to defray necessary expenses.

This law made several changes. It made statutory certain privileges already granted by executive order. It limited as you have seen hospitalization to those who were willing to make oath as to their inability to pay for medical care. A very important feature of the new law is the discontinuance of money payments to the veterans while in the hospital.

As you know the American Medical Association has consistently taken the position that the federal government ought not to provide medical nursing and hospital services for veterans who are able to provide such services for themselves for injuries and diseases in no way related to military service.

The present law goes beyond anything heretofore contemplated in that it provides for free care for nonservice disability. Under the World War Veterans Act 1924 under which the gross abuse of medical nursing and hospital privileges for veterans rich and poor alike suffering from nonservice diseases and injuries grew up hospitalization was absolutely and unqualifiedly

discretionary with the administrator of veterans' affairs, except so far as related to certain named chronic diseases.

The World War Veterans' Act, 1924, section 202, subsection 10, provided:

The Director is further authorized so far as he shall find that existing Government facilities permit to furnish hospitalization and necessary traveling expenses to veterans of any war military occupation or military expedition since 1897 not dishonorably discharged without regard to the nature or origin of their disability. Provided that preference to admission to any Government hospital for hospitalization under the provisions of this subdivision shall be given to those veterans who are financially unable to pay for hospitalization and their necessary traveling expenses.

If under the proviso set forth above, any effort was ever made to classify applicants for hospitalization at the expense of the taxpayers generally, in the order of the ability of the applicants to pay for medical, nursing and hospital services, it was never apparent. As a matter of fact, veterans themselves resented the inquiry into their financial resources and any implication that hospitalization at the expense of the taxpayers generally was given them because of their need and not as a matter of absolute right. It was under this strictly permissive clause in the act of 1924 that the hospital building program of the Veterans Administration costing tens of millions of dollars, developed and was carried into effect.

From our experience in the past we hope that the Veterans' Bureau will be able to resist prescribing a form which would liberalize the amended law beyond interpreting the oath to mean that the veteran is in actual need.

We certainly must see that the regulations will make it extremely difficult for a veteran to accept charity when he is able to pay something to his home doctor and community hospital for services required. We should oppose a loose construction of law which would enable a veteran to escape his civic responsibility.

Can we not assume that the majority of veterans will agree with the citizenship generally that this law should be interpreted for the needy and that an oath to the contrary should not be lightly regarded?

Our attention has been called to the plan now in effect in Illinois. Dr Fredrickson in collaboration with Dr T B Williamson has organized a medical commission composed of district county and post surgeons of the Illinois Department, American Legion. This commission acts as advisers to the Rehabilitation Committee in the interests of the ex-service men. Its great success has been in improving this service while preserving the worth while ideals of the medical profession. Since all problems involving compensation are medical problems, it is to the best interest of the ex-service men and the medical profession that this service be rendered by doctors who have a broad understanding of all the interests involved. An adoption of this Illinois plan by other legion departments would promise much for a closer cooperation between these two great organizations.

If we perform our full duty, and as individuals work faithfully we shall develop a strong sentiment in favor of rendering governmental aid where it is actually needed. No one will be better able to bring about cooperation than the post surgeon.

For the present there has been no effort to bring about increased hospital facilities, and without an increase of such facilities the evil effect on the profession will lessen, because many of these hospitals will be diverted into domiciliary homes.

On the other hand if the oath required by the law, wherein the veteran swears his inability to defray necessary expenses, is treated lightly we shall then be confronted with a serious situation. We should now help to create a sentiment of merited scorn for the veteran who is willing to cheat and accept gratuities from his government which is already burdened with indigence rampant in every direction. This sentiment must be widespread or a new program of hospital building will be launched to meet the demand from sources able to pay for medical care.

We should encourage those fine leaders in the American Legion who do not desire to further a program which is morally and financially destructive to the American people and disastrous to the voluntary hospitals and to the medical profession.

In closing we would like to commend the medical leaders of the states who have influenced rather definitely their represen-

tatives in Washington. At the head of this list comes Virginia, whose representatives, we are glad to report, supported the veto of the President 100 per cent.

We are convinced that if medical men throughout the country would become interested in the candidacy of those who, regardless of party, hold views in harmony with our profession it would not be long until we would have in Congress a very positive influence.

Such influence cannot be created over night. It can be greatly developed at this season and definitely crystallized in the November elections if the members of the medical profession will rally to their duty.

No legislative committee can be stronger than the will of the profession and this professional will to stand together and fight the battles for the future of medicine. This sentiment must be inculcated into the minds of every doctor in this land.

We firmly believe that it requires persistent effort on the part of the leaders of every state in presenting this problem to each and every unit of the national organization.

If our profession is to be effective in state legislation and in the halls of Congress, politicians must learn of our solidarity, of our deep interest in the progress of the science of medicine and of our determination to preserve the integrity of its application in the interest of human beings, all of which makes it essential that we protect the welfare of the profession as a whole so that its dignity and its rights and privileges shall be preserved.

Respectfully submitted

E. H. CARY, Chairman
F. S. CROCKETT
C. B. WRIGHT

NEW BUSINESS

Resolution Authorizing Section on Radiology to Invite Fifth International Congress of Radiology to be Held in America

Dr. Albert Soland, Section on Radiology, presented the following resolution, which was referred to the Reference Committee on Sections and Section Work.

WHEREAS The International Congress of Radiology which convenes every three years has already had three such meetings abroad in London in 1925 in Stockholm in 1928 in Paris in 1931 and now in Zurich in 1934 and

WHEREAS The radiologists of the United States desire to invite the European radiologists to America for the 1937 International Congress and

WHEREAS In the opinion of members of the Section on Radiology of the American Medical Association such an international meeting would at this time engender a national good feeling and would be of high value to scientific radiology be it therefore

Resolved That the House of Delegates of the American Medical Association authorize the Section of Radiology to cordially invite the fifth International Congress to be held in America at such time and place as may be decided on by the International Committee of the Fifth Congress of Radiology.

Resolutions on Exploitation of Roentgenologists in Hospitals

Dr. Albert Soland, Section on Radiology, presented the following resolutions, which were referred to the Reference Committee on Medical Economics.

WHEREAS It has been reported to the officers and members of the Section of Radiology of the American Medical Association that an intolerable condition exists between certain otherwise acceptable hospitals and their departments of radiology and

WHEREAS It is known that in several such hospitals the business management does the collective bargaining for x-ray business with staff members and outsiders to the detriment and professional and financial loss of their staff roentgenologists and

WHEREAS Such practice is not only unethical but places such hospitals on a direct competitive medical practice basis with their respective roentgenologists which practice has been declared illegal in several states and

WHEREAS The practice of roentgenology or radiology is *ipso facto* the practice of medicine and cannot be separated therefrom be it therefore

Resolved That the House of Delegates of the American Medical Association go on record as opposing the exploitation of members of their own body in the manner outlined and be it further

Resolved That the House of Delegates of the American Medical Association in session duly assembled orders this resolution to be referred to the Council on Medical Education and Hospitals for the study and formulation of plans tending to the abatement of these highly unprofessional and obnoxious evils.

Resolutions on State and Federal Relief Committees

Dr. Ralph A. Fenton, Oregon, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations.

1. *Resolved* That each state and federal relief committee engaged in the apportionment of federal relief funds shall include a physician among its members.

2. *Resolved* That no schedule of fees for medical services to indigent beneficiaries of federal relief funds shall be approved by state relief committees without the approval of the state medical society concerned.

The governor of the state of Oregon has appointed Dr. R. L. Benson at the request of the Oregon State Medical Society, to the state emergency relief committee.

Resolution Approving Aims and Purposes of the Society for the Prevention of Asphyxial Death

Dr. George W. Kosmak, New York, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health.

WHEREAS It is now accepted that asphyxia plays a wider role than was formerly understood in death from other causes than mechanical suffocation, and

WHEREAS The total toll of all asphyxial deaths is large and

WHEREAS It is known that many such deaths could be averted by prompt and proper use of modern measures and equipment for the relief of the element of asphyxia and

WHEREAS The Society for the Prevention of Asphyxial Death has been organized for the purpose of saving lives that would without up-to-date management be lost because of failure to relieve asphyxia and

WHEREAS That society has the approval of leaders in medical thought and administration therefore be it

Resolved That the Medical Society of the State of New York approves the aims and purposes of the Society for the Prevention of Asphyxial Death and instructs the delegates to the House of Delegates of the American Medical Association to sponsor a similar resolution at the next meeting of the American Medical Association.

Nomination for Honorary Fellowship

Dr. Arthur H. Curtis, Section on Obstetrics, Gynecology and Abdominal Surgery, presented the following nomination, which was referred to the Council on Scientific Assembly.

The Section on Obstetrics, Gynecology and Abdominal Surgery instructs me to place in nomination for Honorary Fellowship the name of Howard Atwood Kelly, Baltimore. I take pleasure in nominating Dr. Kelly for Honorary Fellowship.

Resolutions Opposing the Exploitation of Drugs, Remedies, etc., Over the Radio

Dr. C. S. Skaggs, Illinois, introduced the following resolutions which were referred to the Reference Committee on Hygiene and Public Health.

WHEREAS The health of the citizens of the United States constitutes the greatest asset of the nation and the responsibility of conserving the health of the citizens and restoring them to health in times of illness reposes in the medical profession and

WHEREAS This responsibility is very great as is evidenced by the high educational and professional standards which physicians are required to meet in the various states of the Union before being permitted to diagnose disease and treat the sick and

WHEREAS Satisfactory and safe service of this type can only be rendered after a long and careful study of the causes and symptoms of disease and that these causes and symptoms can only be determined after an interview with and physical examination of the patient and,

WHEREAS No rational or safe treatment can be decided on and carried out under circumstances other than those above set forth without danger to the life or health of the patient and

WHEREAS For many months past the radio broadcasting companies of the United States have through their various broadcasting stations permitted the exploitation of many drugs, preparations, patent medicines and so called cures to the radio audiences of America and

WHEREAS It has been well established that some of the drugs, preparations and patent medicines so exploited are dangerous in the hands of the layman, others are of doubtful value and in practically all instances their value for the relief of the symptoms and conditions for which recommended have been overstated and are misleading to the public and

WHEREAS The symptoms and conditions for which these drugs, preparations and patent medicines are recommended may be and frequently are indications of serious conditions calling for careful study on the part of a well qualified physician in order that a correct diagnosis may be made and the proper treatment instituted before the disease reaches an advanced stage and

WHEREAS Radio broadcasting is under the control of the Federal Radio Commission and the radio is being used to broadcast non-supportable claims and statements regarding a large number of drugs and preparations for the treatment of human ailments therefore be it

Resolved That the American Medical Association is opposed to the advertising, recommending or in any way exploiting over the radio

any preparations, remedies medicines or appliances for the treatment of human ailments, and that a copy of these resolutions be forwarded to the Federal Radio Commission with a request that in the interest of the health of the citizens of the United States they exercise their authority to discontinue such advertising over the radio. Be it further

Resolved That physicians use such influence with their cooperation in sending protests to the Federal Radio Commission and to broadcasting stations against misleading and unwarranted medical advertising

Resolution Requesting Appointment of Committee to Contact Leaders of Organized Labor

Dr R. L. Sensenich, Indiana, presented the following resolution, which was referred to the Reference Committee on Medical Economics

WHEREAS The legislative program for consideration of the next congress will no doubt include prospective measures of social insurance and

WHEREAS, There are those who strongly favor the including in this program the enactment of legislation creating some form of sickness insurance, and

WHEREAS Ill advised legislation would harmfully affect the group of individuals to whom sickness insurance would be offered as well as the medical profession who would be required to provide the service and

WHEREAS, A review of the history of the creation of sickness insurance as recently reported by the Bureau of Medical Economics of the American Medical Association indicates that the establishment of sickness insurance in Europe has frequently been actuated by political motives or economic purposes not giving full consideration of the best interests or wishes of the groups involved, and in no country have the labor unions led a demand for sickness insurance, and

WHEREAS, In the present period of readjustment of relationship of employer and employee, under guidance of the state the demands of those who will speak for the body of millions of organized labor will be an all important factor in determining the shape any such legislation will take be it therefore

Resolved, That the Board of Trustees be requested to appoint a committee whose duty it shall be, at the proper time to contact the leaders of organized labor, to learn the attitude of the group they represent and in conference with them to present the medical factors involved

R. L. SENSENICH
F. S. CROCKETT
D. F. CAMERON
H. G. HAMER

Resolutions on Advising Broadcasting Systems Concerning Advertising of Proprietary and Household Remedies

Dr Orrin S. Wightman, New York presented the following resolutions, which were referred to the Reference Committee on Hygiene and Public Health

WHEREAS The various broadcasting stations are being used by some drug and patent medicine manufacturers to exploit and make exaggerated and false claims for their products to the serious danger of public health be it

Resolved That the Medical Society of the State of New York go on record as favoring a central national clearing bureau of the medical profession which shall act as a reference committee to confer and advise the broadcasting systems as to the propriety of accepting commercial programs advertising various proprietary and household remedies. Be it also

Resolved That the delegates of the Medical Society of the State of New York to the American Medical Association be instructed to submit this resolution and urge its adoption by that body

Resolutions on Inspection of Hospitals

Dr Burt R. Shurly, Section on Laryngology, Otolaryngology and Rhinology, presented the following resolutions, which were referred to the Reference Committee on Medical Education

WHEREAS, Hospitals have been inspected by laymen without authority who represent in some instances the lower order of government official who make these inspections with reporters to fill the papers with untrue misstatements of fact

WHEREAS Hospitals should be inspected only by duly qualified and authorized persons representing government engineering sanitary and health departments and standardized committees of the American College of Surgeons and those otherwise qualified for this duty

WHEREAS Incompetent and unqualified medical men who are not members of the county societies are often appointed as city and county physicians and as such take on themselves the duty of hospital inspection and the publication of their findings which are often misleading if not in direct contravention of facts and do this from personal and political motives not in accord with public interest and welfare and as the Council on Medical Education and Hospitals has a trained staff of competent and experienced men therefore be it

Resolved That the Council on Medical Education and Hospitals be requested to furnish government officials with a list of properly qualified persons on request with the understanding that expenses are to be met by departments of government requesting such service. Be it further

Resolved That the American Medical Association make every effort to see that city and county physicians and executives of the health depart-

ments are members of the local medical societies and therefore of the American Medical Association. Therefore be it

Resolved That the Council on Medical Education and Hospitals be requested to formulate and promulgate the qualifications and standards for hospital inspection and that such qualifications be supplied to all state county and city governments

Resolutions on Construction of New Building to House the Army Medical Library and the Army Medical Museum

Dr Holman Taylor, Texas, presented the following resolutions, which were referred to the Reference Committee on Medical Education

WHEREAS The greatest medical library in the world one with unrivaled collections of ancient and modern medical literature is maintained in Washington and has served the medical profession of the country efficiently for more than a century, having been called America's greatest contribution to medicine and

WHEREAS In the same building is located the largest medical museum in the United States, and one of the most extensive in the world, an institution which also serves the entire medical profession of the country, and

WHEREAS The building housing these two magnificent scientific institutions is no longer of sufficient size, not fire proof and wholly inadequate to permit the present activities of the Army Medical Library and Army Medical Museum to be carried on to the fullest extent and

WHEREAS, the building in which the two institutions are located has been condemned as a fire hazard and cannot with safety support the weight of the collections of books and museum specimens and because the present building must be removed in order that the approved program of the Congress for the beautification of the city of Washington may be carried out and

WHEREAS The Secretary of the Interior, who is also the Administrator of Public Works notified the Secretary of War on Feb. 14, 1934 that the present building housing the Army Medical Library and Army Medical Museum interfered with these plans and should be removed, and

WHEREAS The appropriation of a large sum of money for public works is now being considered by the Congress and

WHEREAS The medical profession of America is vitally interested in this medical library and museum both of which are serving the medical profession efficiently and at a minimum of expense, and

WHEREAS At the meeting of the American Medical Association held at Milwaukee on June 13, 1933 resolutions were adopted urging that the funds necessary for the construction of a suitable building for the Army Medical Library and Museum be provided and that the building be constructed on the site adjacent to the Walter Reed General Hospital specifically provided by Congress for this purpose more than twelve years ago, Now therefore, be it

Resolved That the American Medical Association in annual meeting assembled respectfully requests that there be set aside for the construction of a new building for these two institutions at the Army Medical Center the sum of \$2,086,000 and be it further

Resolved That copies of this resolution be sent to the President of the United States the Secretary of War and the Administrator of Public Works with the earnest request that the construction of his project of national importance be expedited

Resolutions Urging Congress to Provide Funds for Acquisition of Books, Journals and Other Publications for the Army Medical Library

Dr Holman Taylor, Texas, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations

WHEREAS, The Army Medical Library in Washington is the largest medical library in the world and for many years has acquired every book pamphlet and journal of value in any of the medical sciences (including dental and veterinary science) thereby building up a priceless collection of material available to the entire medical profession of the nation either by personal consultation at the library, or through its interlibrary loan system and

WHEREAS Through the publication of the *Index Catalogue* since 1880 this enormous mass of material more than a million items in number has been completely indexed so that readers without difficulty may find material on any medical subject or by any author and

WHEREAS This *Index Catalogue* now in its forty-eighth volume is the world's standard of medical bibliography being used as a reference in every civilized land and being on deposit in all of the medical schools' medical libraries and the larger general libraries of the United States and

WHEREAS During recent years the funds available to the Army Medical Library have been so reduced as to render it necessary to reduce the purchases of medical books and journals, and likewise the binding of journals and books which require it and

WHEREAS In addition to reductions in appropriations the fall of the dollar in terms of European and other foreign currencies has in effect still further reduced the funds available for foreign purchases by approximately half such foreign purchases being the bulk of the expenditures of the Army Medical Library and

WHEREAS The reduction in the funds appropriated by the Congress to defray the cost of binding books and journals has made it impossible to

bind more than a fraction of the material which requires binding in order to preserve it the remaining material therefore being unavailable for loans outside the library to the great inconvenience and loss to the medical profession of the United States, and

WHEREAS, A number of scientific journals have patriotically agreed to continue to send their publications to the Army Medical Library for the present year without cost in the hope that additional funds may later be made available to continue subscriptions for journals as in the past thus preventing gaps among the splendid files of scientific journals in the Library's collection but that such free subscriptions will probably not be extended beyond the present year, and

WHEREAS Through no fault of the Army Medical Library but under the operations of the Economy Act of 1933 funds for the printing of the first two volumes of the fourth series of the *Index Catalogue* reverted to the Treasury of the United States amounting in all to \$43 000 because the printing had not been completed by June 30 1933 and

WHEREAS The failure to make available funds for the printing of the *Index Catalogue* the material for several volumes of which is now ready to be printed has made it impossible to continue the publication of a volume of this great work each year as has been the practice without interruption even in time of war, since its first volume appeared in 1880 now therefore be it

Resolved That the American Medical Association in annual meeting assembled respectfully urge Congress hereafter annually to include in the appropriation for the support of the military establishment adequate funds for the acquisition of the important books journals and other publications in the medical sciences for the Army Medical Library and for the binding thereof and the publication of the *Index Catalogue* at the rate of approximately one volume per year hereafter and in immediate appropriation of \$50 000 to be used for the publication of the first two volumes of the fourth series of the *Index Catalogue* to cover the gap created by the failure to print these two volumes in 1933 and 1934 and be it further

Resolved That copies of this resolution be sent to the President of the United States the Vice President of the United States the Speaker of the House of Representatives the Secretary of War the chairmen of the Military Affairs Committees of the Senate and House of Representatives and the Chairman of the Appropriations Committees of the Senate and House of Representatives urging them to do all in their power to bring about the legislation necessary to accomplish the purpose of this resolution which has the support of more than a hundred thousand American physicians

Resolution on Establishment of Standards, Ratings and Inspection of Training Schools in Physical Therapy

Dr C B Reed, Illinois, presented the following resolution, which was referred to the Reference Committee on Medical Education

WHEREAS There is a recognized demand for qualified professionally trained physical therapy technicians in the hospitals clinics physicians offices and schools for crippled children of this country and

WHEREAS The work of these technicians is under the direction of members of the medical profession and

WHEREAS The medical profession and the American Physiotherapy Association recognize the vital importance of establishing minimum standards of training and the inspection of training schools in physical therapy by a qualified and authoritative organization therefore be it

Resolved That the entire subject be left to the Board of Trustees of the American Medical Association with the request that it be given careful study and consideration and if practical and feasible some plan for the establishment of standards ratings and inspections of training schools in physical therapy be effected providing that the expense of such inspection be borne by the school requesting the same

Resolution on Standing of Certified Raw Milk

Dr A J Scott Jr, California, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health

WHEREAS The California Medical Association is informed that the American Medical Association through one of its departments favors the pasteurization of milk including certified raw milk and

WHEREAS Certified raw milk only is safe therefore be it

Resolved That the delegates to the American Medical Association be instructed to enlist the aid of the Section on Pediatrics or other interested groups and take such action as may be necessary in their discretion to restore the standing of certified raw milk.

Resolutions on the Necessity of Institutions Being on Approved Lists of Component Societies

Dr Emmett P North, Missouri, presented the following resolutions, which were referred to the Reference Committee on Medical Education

At the seventy-seventh annual meeting of the Missouri State Medical Association, held in St Joseph May 7-10 1934, the following resolutions were introduced by Dr R B H Gradwohl, St Louis, and on motion duly seconded the resolutions were adopted

WHEREAS Definite policies are now in operation and in the process of development in various parts of the country with the object of attaining the cooperation of hospitals clinics medical colleges and like

institutions in observing the economic and ethical principles enunciated by component local societies in affiliation with the Missouri State Medical Association and

WHEREAS As a result of the promulgation of these policies by component units of the Missouri State Medical Association definite 'approved lists of hospitals, clinics medical colleges and like institutions are properly being compiled therefore be it

Resolved That the Missouri State Medical Association memorialize the American Medical Association and instruct its delegates thereto to request the American Medical Association to adopt policies by which the American Medical Association shall not approve any institution for any purpose unless and until such institution shall be officially in the approved list of the component medical society or societies in the jurisdiction of which such hospital or institution is located or operates be it further

Resolved That any institution failing of approval of the society or societies concerned shall have the right of appeal to and hearing before the proper committee of the American Medical Association

Resolution Limiting Physicians on Staffs of Hospitals Approved for Intern Training to Members of Component County Medical Societies

Dr G Henry Mundt, Illinois, presented the following resolution, which was referred to the Reference Committee on Medical Education

Resolved That it is the opinion of the House of Delegates of the American Medical Association that physicians on the staffs of hospitals approved for intern training by the Council on Medical Education and Hospitals should be limited to members in good standing of their local county medical societies and that the House of Delegates requests the Council on Medical Education and Hospitals to take this under advisement

Resolution Requesting Federal Authorities to Undertake Studies of Chemical Content and Value of Foods in Collaboration with Selected Medical Colleges and Research Laboratories

Dr Edgar A Hines, South Carolina, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health

WHEREAS Food is of fundamental importance in the preservation of health and well being and

WHEREAS Relatively little scientific information exists and is available in regard to the chemical constituents of foods including their mineral and vitamin content and

WHEREAS Further scientific information is essential in order to determine the relationship of foods to health and disease and

WHEREAS Federal funds have already been appropriated for relief purposes that might properly be allocated for measures directed toward the improvement of the food supplies of the people of the United States therefore be it

Resolved That the federal authorities be urged by the American Medical Association to undertake studies of the chemical content and value of foods and that these studies be conducted in collaboration with selected medical colleges and research laboratories in different sections of the country

Resolutions Opposing the Administration of Anesthetics by Any One Except a Licensed Physician or Dentist

Dr James N Vander Veer, New York presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business

WHEREAS At the time of the passage of the medical practice act and for many years thereafter it was the accepted interpretation that the administering of an anesthetic by any one except a licensed physician or dentist was illegal and this also was evidenced by the ban on the administering of anesthetics by duly licensed osteopaths and

WHEREAS During the past ten years or so there has been an insidious usurping of the duties and rights of duly licensed physicians by lay technicians and nurses who administer anesthesia despite the fact that there has been no change in the medical practice act and

WHEREAS During this same period there have been marked advances in the physiologic chemical mechanical and therapeutic problems involved in anesthesia to none of which nonmedical technicians have made any contribution and

WHEREAS These advances have reached a stage where they require a medical education for their proper interpretation and safe utilization and

WHEREAS The present custom in many hospitals of having nonmedical technicians administer anesthetics deprives the residents or interns of opportunities for instruction in this important branch of medicine yet these same doctors untrained in anesthesia will subsequently be the ones the law assumes to be qualified to give supervise and accept full responsibility for the administration of the anesthesia and

WHEREAS The inroads of these technicians have tended to discourage medical graduates from entering this field of medicine and have decreased

the likelihood of qualified medical successors to those who have been so instrumental in advancing the art and science of anesthesia and

WHEREAS, The giving of an anesthetic involves on the part of the operator the exercise of judgment discretion and skill and is not merely a mechanical performance which can be routinely performed by any untrained individual without jeopardy to the patient and

WHEREAS The successful administration of anesthesia requires the exercise of proper medical care during the procedure and involves an examination of a patient to determine his physical ability to undergo the process and a careful watching of the patient during the administration of the anesthesia to determine its effects and the quantity administered and

WHEREAS The prevalent custom of evasion of the spirit of the law by the technical assumption of responsibility by the operating surgeon is a mere subterfuge as the surgeon in most hospitals rarely selects or inquires into the technician's qualifications, does not usually supervise the administration of the anesthetic at its most critical period namely the induction and even though present during its maintenance the surgeon because of his interest in the operative procedure cannot always promptly detect the necessity for therapeutic intervention which determination must be left to the judgment of the anesthetist and

WHEREAS Many hospitals and private sanatoriums advertise to the public and the profession that an anesthetist will be available this being a misrepresentation when such anesthetist is only a technician while the general assumption is that the term anesthetist implies a physician and

WHEREAS Since the surgeon is by law responsible for the act of an agent if in fact the lay anesthetist is the doctor's agent when administering an anesthetic the surgeon assumes a responsibility and liability which under certain circumstances may nullify the effect of his malpractice coverage if it can be proved that such lay anesthetist is performing an unlawful or illegal act, and

WHEREAS Our acquiescence to the encroachment by nonmedical technicians in the field of anesthesia on the prerogatives of the physicians will make it increasingly difficult to exclude the osteopaths and others from these same privileges for if any division of medicine desires to nullify any section of the medical practice act it can do so by the subterfuge or assuming the responsibility then other divisions of medicine must in justice be accorded the same privilege and the whole act be thus weakened therefore be it

Resolved That the Medical Society of the State of New York affirm that the giving of an anesthetic constitutes the practice of medicine and insist on the strict observance of the provisions of the medical practice act without subterfuge or evasion and be it further

Resolved That the delegates of the Medical Society of the State of New York to the American Medical Association be instructed to present a similar resolution to the House of Delegates of the American Medical Association at the impending session in Cleveland

Resolutions on Preparation of Extensive Photographs and Other Data and Information of Exhibits at Chicago International Exposition

Dr Clarence G Toland, California, presented the following resolutions, which were referred to the Board of Trustees

WHEREAS Several of the constituent state medical units of the American Medical Association maintain yearly public health exhibits at their state and county fairs and

WHEREAS At the Century of Progress International Exposition at Chicago comprehensive exhibits of the scientific and other progress of medicine are being displayed which exhibits have great suggestive value for constituent state and component county medical societies interested in producing and maintaining such exhibits in their respective districts, and

WHEREAS The amount of definite informative data on these matters in the files of the American Medical Association has not been overgreat now therefore be it

Resolved That the matter be called to the attention of the House of Delegates of the American Medical Association at the forthcoming Cleveland Session in the hope of securing the endorsement of that House to the plan of having the Board of Trustees of the American Medical Association order the preparation of extensive photographs and other data and information of those exhibits at the Chicago International Exposition which if duplicated or modified could be advantageously and economically reproduced or used as exhibits of constituent state and county medical associations and be it further

Resolved That the California Medical Association delegates be instructed to present this resolution to the House of Delegates of the American Medical Association for its consideration

Resolutions Barring from the Practice of Radiology All Persons Not Licensed to Practice Medicine

Dr George M Fisher New York, presented the following resolutions which were referred to the Reference Committee on Medical Education

WHEREAS The making of a diagnosis by means of the x rays and for the administration of x rays or other radiant energy for treatment are methods of diagnostic or therapeutic medical practice and

WHEREAS The medical practice act makes the diagnosing and/or treatment of disease unlawful for any one not duly licensed to practice medicine and

WHEREAS During the past ten years or more lay persons and lay organizations have established and are conducting x ray laboratories in

which lay persons are examining and/or treating patients by means of x rays and

WHEREAS Such lay persons are not properly qualified and are not subject to effective supervision or control and

WHEREAS, The x rays in the hands of inexperienced and/or irresponsible persons are in themselves a potential source of injury to the patient and

WHEREAS In addition to these dangers x ray diagnosis frequently requires the administration of potent drugs or chemicals which may be legally administered only by licensed physicians and

WHEREAS Under these conditions the lay x ray operator and the commercial x ray laboratories constitute a menace to the public and in addition are strictly commercial enterprises conducted by business getters who are actuated by the profit motive and who consequently do not feel themselves bound by the rules of medical ethics but who resort to all sorts of questionable methods to attract a compliant clientele and

WHEREAS By the employment of solicitors runners and/or other business agents and by the promise of rebates or of favorable or dishonest diagnoses obtain the patronage of unscrupulous physicians or of business and industrial organizations to the detriment of the patient and

WHEREAS Because of their illegal activities and the desire for profit they have been unable to attract competent physicians adequately trained in radiology and as a result employ the services of individuals whose education, training and character are unacceptable to right thinking members of the medical profession or to the American Medical Association and

WHEREAS The technical diagnostic and therapeutic advances being made in radiology are due to and dependent on properly trained physicians to whom science must look for further progress in the field of radiology and

WHEREAS The lay x ray technicians and laboratories have so encroached on the practice of radiology that competent and ethical medical practitioners find it more and more unattractive as a field of endeavor thus endangering the progress and advancement of the science of radiology and the welfare of the public be it therefore

Resolved That the House of Delegates in convention assembled believes that the practice of radiology whether for diagnostic or therapeutic purposes constitutes in fact the practice of medicine and be it further

Resolved That the properly constituted authorities be called on to take the requisite steps to bar all persons not licensed to practice medicine in the state of New York from the practice of radiology and be it further

Resolved That if it is the opinion of the Attorney General that non medical technicians practicing radiology are not violating the law under present conditions such steps be taken to institute legislation which will include radiology in the practice of medicine and to limit diagnostic or therapeutic x ray work to the direct and active supervision and control of duly licensed physicians or dentists, and be it further

Resolved That our delegates from New York to the American Medical Association be instructed to bring this matter to the attention of the House of Delegates of the American Medical Association at the impending session

Resolutions on Discrimination Against Certain Members of the Medical Profession

Dr Edward R Cuniffe, New York, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations

WHEREAS Civilized peoples have never discriminated against any one who contributes to medical science or against one who is qualified to engage in the healing of the sick because of his race or religious belief, or economic views

WHEREAS Under the Nazi regime by governmental decrees and other wise persons engaged in research or the practice of medicine have been either harried or expelled from their laboratories and clinics without justice or reason other than that they differed in racial origin or religion from that of their colleagues, and

WHEREAS Our brother physicians are not permitted to participate in the health insurance service and are permitted to consult only with physicians designated by the German government and expelled from medical societies and clubs in spite of their previous noteworthy contribution to science and medicine and

WHEREAS Such discrimination tends to hamper the efforts of the profession in its chosen task of combating disease and alleviating suffering and

WHEREAS German medicine previous to the past year has made outstanding contributions in the field of human progress and

WHEREAS The measures instituted by the present Nazi government are doing incalculable harm to the progress of medicine throughout the world therefore be it

Resolved That the New York Medical Society record its abhorrence and voices its resentment against such practices as being unfair inhuman and inimical to progress of medicine generally and a violation of those humane ideals which are among the cherished traditions of the medical profession and be it further

Resolved That the delegates of this house to the American Medical Association be instructed to register the protest of this body

Resolution on Publicity by Clinics, Hospitals, Sanatoriums and Other Semipublic Medical Institutions

Dr Ben R McClellan, Ohio presented the following resolution, which was referred to the Judicial Council

WHEREAS There are occasional evidences of advertising, publicity and propaganda by certain large clinics in violation of the proper ethical

and professional restrictions placed on individual physicians therefore be it

Resolved By the House of Delegates of the American Medical Association at the Eighty-Fifth Annual Session in Cleveland June 11 to 15 1934 that attention of the county medical societies be called and emphasis again placed on the following declaration of policy and principle incorporated in resolutions adopted by this body in 1924

1 Publicity by clinics hospitals sanatoriums and other semipublic medical institutions as to quality of work done implies unusual and exceptional ability and efficiency on the part of their professional staffs and therefore is advertising of the medical men concerned This type of advertising distinctly savors of quackery and is unethical

2 Publicity by any such institution stating or implying that, by reason of its exceptionally fine equipment and material resources it is able to or does give the public better medical service than similar institutions are able or willing to render is advertising for purposes of self aggrandisement Statements of this type are frequently exaggerated and misleading and are detrimental to the best interests of the public of the institution concerned and of true medical progress Publicity of this kind is unethical

Resolution on Health Insurance from Michigan State Medical Society

Dr Carl F Moll, Michigan, read the resolution on health insurance from the Michigan society Dr J H J Upham, chairman of the Board of Trustees, offered a recommendation from the Committee on Executive Session that this resolution be considered in executive session on Monday afternoon A motion to that effect was made by Dr Moll, seconded by Dr Arthur J Bedell, New York, and carried On motions of Dr Bedell, duly seconded, the House voted to call the executive session for 2 p m, Monday, June 11, and to limit attendance to members of the House of Delegates

Resolution on Free Choice of Physician

Dr Arthur J Bedell, New York, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations

WHEREAS The procedures established by the Federal Compensation Bureau do not allow free choice of physicians and

WHEREAS The physicians as citizens should not be discriminated against in their professional work be it

Resolved That the House of Delegates instruct its delegates to the American Medical Association to present this matter and urge the Association to attempt a change of rules of the Federal Compensation Bureau which will allow the injured person free choice of physician

Resolution on Perfecting of a Plan for the Handling of Liability Insurance

Dr Horace Reed, in behalf of the Oklahoma delegation, presented the following resolution, which was referred to the Board of Trustees

WHEREAS That the House of Delegates of the Oklahoma State Medical Association hereby specifically instruct their Delegates to the American Medical Association to introduce a resolution in the House of Delegates of the American Medical Association favorable to the instituting of liability insurance to members by the American Medical Association

Amended to Read That our delegates to the American Medical Association investigate as to the feasibility of the American Medical Association perfecting a plan for the handling of liability insurance

Resolution Limiting Approval of Institution

Dr Horace Reed, in behalf of the Oklahoma delegation, presented the following resolution, which was referred to the Judicial Council

WHEREAS Definite policies are now in operation and in the process of development in various parts of the country with the object of attaining the cooperation of hospitals clinics medical colleges and like institutions in observing the economic and ethical principles enunciated by component local societies in affiliation with the Oklahoma State Medical Association and

WHEREAS As a result of the promulgation of these policies by component units of the Oklahoma State Medical Association definite approved lists of hospitals clinics medical colleges and like institutions are properly being compiled therefore be it

Resolved That the Oklahoma State Medical Association memorialize the American Medical Association and instruct its delegates thereto to request the American Medical Association to adopt policies by which the American Medical Association shall not approve any institution for any purpose unless and until such institution shall be officially in the approved list of the component medical society or societies in the jurisdiction of which such hospital or institution is located or operates Any institution failing of approval of the society or societies concerned shall have the right of appeal to and hearing before the proper committee of the American Medical Association

Amendments to Principles of Medical Ethics

Dr George Edward Follansbee, Chairman of the Judicial Council, presented the following three amendments to the Principles of Medical Ethics, which were referred to the Reference Committee on Amendments to the Constitution and By-Laws

1 WHEREAS The Judicial Council in its report to the House of Delegates at the Milwaukee session in 1933 recommended the simplification of the section in the Principles of Ethics relating to contract practice by the addition of the wording appearing later in this resolution and

WHEREAS The recommendation of the Judicial Council was approved by the reference committee to which it was referred and was adopted by the House of Delegates therefore be it

Resolved That the Principles of Ethics chapter II article V, section 2 be amended by adding to the present wording the following

By the term contract practice as applied to medicine is meant the carrying out of an agreement between a physician or a group of physicians as principals or agents and a corporation organization or individual to furnish partial or full medical services to a group or class of individuals for a definite sum or a fixed rate per capita

Contract practice per se is not unethical However, certain features or conditions if present make a contract unethical among which are 1 When there is solicitation of patients directly or indirectly 2 When there is underbidding to secure the contract 3 When the compensation is inadequate to assure good medical service 4 When there is interference with reasonable competition in a community 5 When free choice of a physician is prevented 6 When the conditions of employment make it impossible to render adequate service to the patients 7 When the contract because of any of its provisions or practical results is contrary to sound public policy

Each contract should be considered on its own merits and in the light of surrounding conditions Judgement should not be obscured by immediate temporary or local results The decision as to its ethical or unethical nature must be based on the ultimate effect for good or ill on the people as a whole

2 WHEREAS The growth of groups and clinics has intensified the economic competition between them and individual practitioners and

WHEREAS The common custom of employment of 'business managers' by the clinics and groups has had a tendency to submerge the ethical principles governing competition among doctors and

WHEREAS Clinics and groups were little known were not serious competition and were not mentioned when the present general revision of the Principles of Ethics were adopted in 1912 be it

Resolved That the Principles of Ethics be revised as follows

Chapter 1 shall read (heading) In General

Section 1 to remain as it is

Section 2 to be added as follows (heading) Groups and Clinics

Section 2 The ethical principles actuating and governing a group or clinic are exactly the same as those applicable to the individual As a group or clinic is composed of individual doctors each of whom whether employer employee or partner is subject to the principles of ethics herein elaborated the uniting into a business or professional organization does not relieve them either individually or as a group from the obligation they assume when entering the profession

The remainder of chapter I becomes chapter II with its present heading

Present section 2 of chapter I becomes section 1 of chapter II

Present section 3 of chapter I becomes section 2 of chapter II

Present section 4 of chapter I becomes section 3 of chapter II

Chapter II becomes chapter III

Chapter III becomes chapter IV

3 *Resolved* That the Principles of Ethics be amended by inserting as section 4 of article VI chapter II It is unprofessional for a physician to dispose of his professional attainments or services to any lay body, organization group or individual by whatever name called or however organized under terms or conditions which permit a direct profit from the fees salary or compensation received to accrue to the lay body or individual employing him Such a procedure is beneath the dignity of professional practice is unfair competition with the profession at large is harmful alike to the profession of medicine and the welfare of the people and is against sound public policy

Recommendation of Joint Meeting of American Medical Association and Canadian Medical Association in 1935

Dr J H J Upham, Chairman of the Board of Trustees, presented the following recommendation, which was referred to the Council on Scientific Assembly

On several occasions the Canadian Medical Association has suggested a joint meeting of the American Medical Association and the Canadian Medical Association This year an invitation was extended to the Association to meet the Canadian Medical Association in Canada—to have its business meeting in the United States and the scientific meeting in Canada

The Board looks with favor on the holding of a joint scientific meeting of the two organizations and recommends to the House of Delegates that an invitation be extended to the Canadian Medical Association to join with the American Medical Association in its scientific program in 1935

The meeting recessed at 12 55 p m to reconvene at 2 p m

Monday Afternoon, June 11

The House of Delegates was called to order at 2 05 p m by the Speaker, Dr F C Warnshuis

Resolutions on Contraceptive Methods

Dr J D Brook, Michigan, presented the following resolutions, which were referred to the Reference Committee on Hygiene and Public Health

WHEREAS Innumerable devices, chemical substances technics and safe period calendars are being offered to the public for the purposes of contraception, and

WHEREAS Members of the medical profession are constantly asked by the public to advise them relative to the scientific efficacy of such materials and methods and the conditions that justify their employment therefore he it

Resolved 1 That the House of Delegates create a special committee of five on the study of contraception to be appointed by the Speaker with the advice of the Executive Committee of the Board of Trustees

2 That this committee be instructed to study the problem of birth control in all its medical aspects particularly as they relate to methods conditions indicating their employment and the best manner of imparting instruction thereon to physicians and to the lay public,

3 That this committee be provided by the Council on Pharmacy and Chemistry with a statement of the therapeutic value and effectiveness of contraceptive preparations that are or may be offered by manufacturers and that the Board of Trustees be requested to instruct this council and other appropriate committees to render all reasonable assistance and advice to this special committee and

4 That the Board of Trustees provide this special committee with a fund to be determined after conference with the committee chairman for clerical and correspondence expenses and be it further

Resolved That the report of this special committee together with all its findings and recommendations be not dislodged until it has been presented at the 1935 executive session of this House of Delegates for consideration and affirmative action by this House of Delegates, and be it also

Resolved That the appointment of this special committee shall in no way be construed as an endorsement of birth control on the part of the American Medical Association, and that the appointment of this committee is for the purpose of compiling dependable facts for future guidance

Resolution on Apparent Attempt of Board of Regents of the American College of Surgeons to Dominate and Control Medical Practice

Dr Charles J Whalen, Illinois, presented the following resolution, which was referred to the Judicial Council

WHEREAS The American Medical Association including in its membership almost 100 000 physicians is the only body representing all of the organized profession of this country through delegates regularly elected through county and state medical societies, and

WHEREAS Various similar medical organizations and groups, including in their membership selected groups of specialists of various types, have from time to time issued pronouncements of policies in the field of medical economics and medical practice which do not represent the views of organized medicine and

WHEREAS The House of Delegates of the American Medical Association has repeatedly condemned the issuing of such announcements and policies which seriously embarrass the attempts of your organization to secure adequate care for the health of the American people and to protect the ideals of the medical profession and

WHEREAS The Board of Regents of the American College of Surgeons as embodied in Chicago on Sunday June 10 promulgated a policy including a prepayment plan for medical care restricted to the hospitals approved by the American College of Surgeons to members of the staffs of such hospitals and to physicians acceptable to such staffs and

WHEREAS This action of the Board of Regents of the American College of Surgeons has been spread to the people of the United States through the press on the opening day of the annual session of this House of Delegates therefore he it

Resolved That the House of Delegates of the American Medical Association express its condemnation of such tactics and of this attempt of the Board of Regents of the American College of Surgeons to dominate and control the nature of medical practice to the detriment of professional ideals and the welfare of the public.

Resolution on Composition of Council on Physical Therapy

Dr Joseph F Smith Wisconsin, presented the following resolution, which was referred to the Board of Trustees

WHEREAS The Board of Trustees of the American Medical Association, pursuant to a resolution passed by the House of Delegates of the American Medical Association at its 1925 session established a Council on Physical Therapy consisting of two physicians two physiologists two pathologists and two clinicians whose duty it should be to investigate scientifically and report on the value and merits of all nonmedicinal apparatus and contrivances offered for sale to physicians and hospitals and to publish in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION from time to time the results of their investigation and

WHEREAS The Council so appointed has done most excellent work in determining the merits and demerits of the various types of apparatus offered thereby furnishing to the medical profession a means of ascertaining the reliability and accuracy of various type of physical therapy apparatus and

WHEREAS It seems at this time desirable to continue the Council so constituted as to be equipped for high grade scientific investigation as well as clinical research and

WHEREAS The personnel of the Council as at present constituted does not conform to request of the original resolution as passed by this House of Delegates in 1925 be it

Resolved By this House of Delegates, that the Board of Trustees in making appointments to the Council be requested to conform to the personnel designated in the original resolution and that two physical therapists practicing in reputable institutions or hospitals be added to the Council

The House voted to permit the editor of THE JOURNAL, the director of the Bureau of Legal Medicine and Legislation and the director of the Bureau of Medical Economics to sit in the executive session

Executive Session, Monday Afternoon, June 11

The House of Delegates convened in executive session at 2 15 p m, the Speaker, Dr F C Warnshuis, in the Chair

Dr J H J Upham, Chairman, submitted for consideration by the House of Delegates an official statement of the Board of Trustees

On motion of Dr E H Cary, Texas, seconded by Dr H A Luce, Michigan and carried, after a motion for the House to resolve itself into a Committee of the Whole had lost, the matter was referred to a special committee for report at an executive session on Tuesday afternoon, June 12 The Speaker appointed the special committee as follows N B Van Etten, New York, chairman, J Norman Henry, Pennsylvania, George Blumer, Connecticut C A Dukes, California, McLain Rogers, Oklahoma, E H Cary, Texas, and F S Crockett, Indiana

A motion offered by Dr William D Chapman, Illinois, seconded by Dr R L Green, Illinois, to permit the executive secretaries of state societies to attend the executive session was defeated

The meeting recessed at 2 40 p m, to reconvene on Tuesday morning, June 12, at 9 30

REGISTRATION AT CLEVELAND

The total registration at the Cleveland session was 6,293 Below are given two summaries—one by sections and one by states

Registration by Sections

Practice of Medicine	1 963
Surgery General and Abdominal	1 009
Obstetrics Gynecology and Abdominal Surgery	500
Ophthalmology	374

Association News

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45, Central daylight saving time. The next three broadcasts will be as follows:

June 28 Motor Touring and Camping W W Bauer M D
July 5 Death Angel W W Bauer M D
July 12 A Healthful Vacation, Morris Fishbein M D

National Broadcasting Company

The National Broadcasting Company talks have been discontinued for the summer.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CONNECTICUT

Pediatric Meeting—The New England Pediatric Society convened in annual session, May 19, in New Haven. The program included the following subjects:

Mottled Enamel Arthur H. Smith, Ph.D., and Bert G. Auderson, D.D.S.
Recent Advances in Nutrition of Interest to Pediatricians Lafayette B. Mendel, L.L.D.
Demonstration of Apparatus for Stimulating Excitable Centers for Remote Control Dr. Richard U. Light
The Developmental Diagnosis of Infant Behavior and Its Relation to Clinical Pediatrics Dr. Arnold Gesell
The American Academy of Pediatrics Dr. Louis C. Schroeder, New York
Clinical Presentation Dr. Grover F. Powers and staff of New Haven Hospital

ILLINOIS

Campaign Against Typhoid—The state health department has instituted a vaccination campaign against typhoid in eleven counties in southern Illinois. The work is being carried out in Jefferson and Fayette counties and was scheduled to begin early in June in Saline, Williamson, Jackson, Union, Randolph and Madison counties. It will be extended into the remaining counties as soon as facilities permit.

Chicago

Dr. Evans Retires from the Chicago Tribune—Dr. William A. Evans, professor emeritus of public health, Northwestern University School of Medicine, has retired as health editor of the *Chicago Tribune*, after twenty-three years' service. He will be succeeded by Dr. Irving S. Cutter, dean of Northwestern University School of Medicine.

Society News—Drs. Ralph A. Reis and Robert M. Grier presented "A Comparative Five Year Study of Maternal Mortality at Michael Reese and Evanston Hospitals, 1929-1933" before the fifty-seventh annual meeting of the Chicago Gynecological Society, June 22, and Dr. Edward L. Cornell, "A Preliminary Report on the Maternal Deaths for 1933 in Chicago"—Dr. Ernestine V. Kandel, among others, addressed the Chicago Council of Medical Women, June 1, on "Differential Diagnosis and Therapy in Leukemias."

University Tuberculosis Unit Opened—With the opening of a new tuberculosis unit in the University of Chicago Clinics, June 11, it will be possible to care for these patients for long periods and to treat their tuberculosis as it is treated in tuberculosis sanatoriums, according to the *News Bulletin* of the Division of Biological Sciences. Heretofore tuberculous patients have been admitted to the University Clinics only for diagnosis and treatment of complications. The assembling of these patients on one floor and in the same division will be an experiment it was pointed out to show first whether such a unit may be operated successfully from a medical standpoint and to prove whether the unit may be operated at a cost low enough for the typical sanatorium patient to meet.

Changes at University of Chicago—Dr. Henry L. Schmitz has resigned as assistant professor of medicine, Division of Biological Sciences, University of Chicago, to enter private practice. Other changes on the faculty include the appointment of Dr. Arthur K. Koff as instructor in obstetrics and gynecology, effective July 1, and Dr. Francis Keith Bradford, assistant in neurosurgery. Promotions include:

Dr. Morris Edward Davis, associate professor of obstetrics and gynecology, effective July 1.

Dr. Lowell T. Coggeshall, assistant professor of medicine, effective July 1.

Dr. Theodore E. Heinz, assistant professor of medicine, effective July 1.

Dr. Henry Close Hesselstine, assistant professor of obstetrics and gynecology, effective July 1.

Dr. Normand L. Hoerr, assistant professor of anatomy, effective October 1.

Dr. Frank E. Whitacre, assistant professor of obstetrics and gynecology, effective July 1.

GEORGIA

Society News—Dr. George L. Walker, Jr. presented a paper on "The Measurement of the Work of the Heart and Its Relation to Disease" before the Fulton County Medical Society, June 7.—Dr. Joseph Righton Robertson, Augusta, was chosen president-elect of the Georgia Urological Association at its meeting in Augusta, May 10, and Dr. Walter B. Emery, Atlanta, was installed as president.

Honorary Society Lecture—Dr. Claude S. Beck, associate professor of surgery, Western Reserve University School of Medicine, Cleveland, addressed Caduceus, an honorary medical society of Emory University School of Medicine, May 17, on "The Surgical Relief of Adhesive Pericarditis" and Commemorative Wounds of the Heart. The society recently inaugurated the plan of having an annual lecture.

INDIANA

Memorial to Physicians—Three physicians who are identified with the early history of the James Whitcomb Riley Hospital, Indianapolis, were honored May 18, when tablets were dedicated to their memory. The physicians were John H. Oliver, Lafayette Page and Frank A. Morrison, and eulogies were presented, respectively, by Drs. William P. Garshwiler, Louis Burckhardt and John Cunningham. The three tablets are grouped around a brass figure, about 6 feet in diameter, in the form of a cross. In the center of this design there are medical symbols and in each limb of the cross there are four names of persons prominent in medicine: Hippocrates, Avicenna, Galen, Pare, Vesalius, Harvey, Sydenham, van Leeuwenhoek, Jenner, Virchow, Koch, Pasteur, Long, Beaumont, Roentgen and Walter Reed. The tablets are the work of Harry Inge Johnstone and Donald M. Mattison, both of the Herron Art Institute, Indianapolis. About 250 guests attended the dinner following the unveiling. The guests included the governor of Indiana, the president and board of trustees of the University of Indiana School of Medicine, the mayor of Indianapolis, and living members of the families of the three physicians to whom the tablets were dedicated.

IOWA

Scarlet Fever in Hampton Traced to Raw Milk—Twenty-five cases of scarlet fever, affecting fifteen homes, were reported in an outbreak in Hampton in March. No deaths occurred. The source of the outbreak was traced to a dairy farm where, the subsequent investigation disclosed, several persons had been ill. No physician had been called. Hemolytic streptococci were found in the majority of the patients. The board of health prohibited the distribution of milk by the farm and control measures were instituted. The first case of the outbreak was reported, March 13, twenty were recorded between March 17 and 20, when the distribution of milk was forbidden and the remaining four occurred between that date and April 1.

MAINE

State Medical Election—Dr. John L. Johnson, Bangor, was chosen president-elect of the Maine Medical Association at its annual meeting in Bangor, May 28-29. Dr. Edwin W. Gehring, Portland, was inducted into the presidency. At a banquet, May 29, medals were presented to members who had completed fifty years of practice. Four of the five physicians to be honored were present: Leon L. Hale, South Portland; Albert P. Heald, Thomaston; Charles A. Moulton, Hartland; James S. Sturtevant, Dixfield. Dr. Roscoe G. Blanchard, Dover, N. H., was unable to be present.

Society News—Dr Theodore S Moise, Bangor, addressed a recent meeting of the Cumberland County Medical Society on "Surgical Treatment of Pulmonary Tuberculosis" — Dr Richard S Hawkes, Portland, presented a paper on "Role of Liver, Iron and Copper in the Treatment of Certain Anemias" before the Portland Medical Club, April 3 — At a meeting of the Hancock County Medical Society in Ellsworth, April 25, Drs John G Towne, Waterville, and Carl J Hedim, Bangor, presented papers on "Medicolegal Problems as Applied to the General Medical Man" and "Psychiatric Problems, Border-Line in Nature and the Neuroses," respectively, Dr John L Johnson, Bangor, spoke on insurance and malpractice and Dr Warren E Kershner, Bath discussed the subject — Dr Frederick T Hill addressed the Kennebec County Medical Association in Waterville April 19, on "Treatment of Chronic Deafness, Not an Otological Problem Alone," and Dr Charles Harold Jameson, Rockland "The Prostate Gland" A clinical program was also presented — Dr John O Piper, Waterville discussed "Spontaneous Subdural Hemorrhage" before the Knox County Medical Society in Rockland, April 10 — At a meeting of the Oxford County Medical Association in Bethel May 2 Dr Lester Adams, Greenwood Mountain, spoke on "The Childhood Type of Tuberculosis"

MASSACHUSETTS

Changes at Harvard—Dr John Homans, assistant professor of surgery, Harvard Medical School Boston, has been appointed clinical professor of surgery for three years Other changes on the faculty include Dr Charles C Lund instructor in surgery, named assistant professor for three years, Dr William T Salter, assistant professor of medicine for three years, and Dr James Clark White, instructor in surgery, as assistant professor for three years

Society News—Speakers before the annual meeting of the New England Physical Therapy Society in Boston, May 16, were Drs William D McFee and Halsey B Loder both of Boston, on physical medicine with a consideration to electrotherapy and electrosurgery, respectively — Dr Chevalier L Jackson, Philadelphia addressed the New England Roentgen Ray Society in Boston, May 18 on "Value of Roentgenography in the Diagnosis of Laryngeal Disease"

Lectures on the Electrocardiograph—Dr Frank N Wilson, professor of internal medicine, University of Michigan School of Medicine Ann Arbor, delivered two lectures, at the Boston Medical Library, May 24-25, under the auspices of the New England Heart Association The titles of the lectures were "When Is an Electrocardiographic Examination Indicated and What Sort of Help Can It Give?" and "The Electrocardiographic Diagnosis of Myocardial Infarction"

MICHIGAN

New Health Unit—The establishment of the Van Buren County Health Department has been made possible by the W K Kellogg Foundation It is expected to begin operation on a full time basis July 1 The foundation will supply most of the funds the state the usual annual subsidy of \$3,000, and the county office space and equipment

Society News—Dr Andrew B Rivers, Rochester, Minn, addressed a joint meeting of the medical societies of Ingham, Calhoun and Barry counties, May 14 on ulcers of the stomach — Dr Edgar A Kahn Ann Arbor, addressed a recent meeting of the Calhoun County Medical Society on "Section of Splanchnic Nerves for Malignant Hypertension"

Health Officer Honored—Dr Frank A Tinker, health officer of Lapeer, was given a banquet by the Lapeer County Medical Association May 24 in honor of his completion of fifty years in the practice of medicine Dr Tinker graduated from the University of Michigan Medical School Ann Arbor in 1884 and for the last ten years has been city health officer

Hospital News—In commemorating the seventieth year of the ambulatory service of Harper Hospital a photograph of Dr Charles G Jennings Detroit was unveiled in the department May 11 For twenty years the outpatient service has been housed in the Theodore Buhl Memorial Building, it was Dr Jennings who interested the Buhl family to erect this unit to Harper Hospital Scientific exhibits on the specialties were arranged on the various floors by the divisions of the hospital

Personal—Dr Roman J Sadowski was guest of honor at a dinner May 16 in recognition of his completion of thirty years practice in Detroit An engrossed plaque was presented to Dr Sadowski as a token from the Arts Club of which he is a past president while the eighty-five guests at the dinner presented him with a cellorette — A resolution honoring

Dr Frank A Kelly was recently adopted by the Wayne County Medical Society, in appreciation of his fifteen years' service as an officer Dr Kelly recently withdrew his name for reelection as a member of the board of trustees

MINNESOTA

Society News—Speakers before the Minnesota Academy of Medicine in Minneapolis, May 9, were Drs Harold E Hullsiek, St Paul, and Francis F Callahan, Pokegama, on "The Doctor in Fiction" and "Pulmonary Carcinoma," respectively

Convicted of Harboring an Outlaw—Dr Clayton May, Minneapolis, found guilty, May 23, by a federal court jury of conspiracy to harbor an outlaw, was sentenced to serve two years in prison and fined \$1,000 Dr May is alleged to have treated John Dillinger for a gunshot wound without reporting the incident to the police An appeal will be entered, the Chicago Tribune reported Born in 1887, Dr May graduated from Milwaukee Medical College in 1911 He is not a member of the American Medical Association

MONTANA

Personal—Dr Alonzo T Munro, Kalispell, was elected president of the Montana State Board of Medical Examiners, recently, and Dr Sidney A Cooney, Helena, was reelected secretary Dr Cooney was also reappointed a member of the board for another seven year term

State Medical Meeting at Helena, July 11-12—The fifty-sixth annual meeting of the Medical Association of Montana will be held at the Placer Hotel in Helena, July 11-12, under the presidency of Dr Byron L Pampel, Livingston Dr Louis H Fligman, Helena, president of the Lewis and Clark Medical Society, will give the address of welcome, and Dr William E Long Anaconda, vice president of the state association will respond The scientific program will consist of papers by the following physicians

Ernest Sachs St Louis Present Day Diagnosis and Treatment of Brain Tumors
Walter A Fansler Minneapolis Surgical and Nonsurgical Treatment of Hemorrhoids
Dean Lewis Baltimore, Essentials of a Physician
Juhon E Benjamin, Cincinnati Sudden Death and a Consideration of Its Mechanism
Mynie G Peterman Milwaukee Convulsions in Infancy and Childhood

On Thursday morning, Dr Sachs will discuss "Spinal Cord Lesions" Dr Fansler "Cancer of the Colon", Dr Lewis, "Cancer" Dr Benjamin, "Observations on the Effect of Deep X-Ray Treatment of Agranulocytosis, and the Clinical Effect of Amidopyrine," and in the afternoon Dr Peterman will conclude the scientific session with a talk on "Epilepsy in Childhood"

NEBRASKA

State Medical Election—Dr Claude A Selby, North Platte, was chosen president-elect of the Nebraska State Medical Association at its annual meeting in Lincoln May 24, and Dr Joseph Brxby, Geneva, was inducted into the presidency Dr Roy B Adams Lincoln, was reelected secretary The next annual session will be held at Omaha

Conference on Child Health—A general survey of pediatrics was presented at a conference on child health and protection in Lincoln, May 18, by Dr Clyde N Moore, Omaha Other physicians participating in the conference included

Howard B Hamilton Omaha Nutritional Problems
Floyd S Clarke Omaha Preschool Examination
William O Colburn Lincoln the Handicapped Child
Joseph A Henske Omaha Cardiac Clinic
Ernest W Hancock Lincoln, School Health Program
John H Murphy, Omaha Tuberculosis
Herman M Jahr Omaha The Problem Child
Palmer Findley Omaha Maternity Problems
Earl C Sage Omaha Maternal Mortality in Nebraska
Harold S Morgan Lincoln Prenatal Care
Harry E Harvey Lincoln Lowered Birth Rate

Society News—Dr C A Stewart, Minneapolis was guest speaker at the annual meeting of the Nebraska Tuberculosis Association in Lincoln, May 22, on childhood tuberculosis — At the semiannual meeting of the Third Councilor District Medical Society in Tecumseh, April 18, speakers included Drs Harry M Hepperlen Jr Beatrice, on "Pathology of Uterine Bleeding", Edward S Maloney, Omaha "Asthma in Children and Adults," and Hiram Winnett Orr, Lincoln "Fixed Versus Elastic Traction in Fractures" — Three Omaha physicians presented the program of the Sixth Councilor District Medical Society, Shelby, April 11, as follows Drs Maurice C Howard "Medical Management of Biliary Disease", R Russell Best "Surgical Considerations and the Complications in Gallbladder Disease" and John A Borghoff "Eczema—Common

Cause"—Dr J Calvin Davis Jr, among others, addressed the Madison-Six Counties Medical Society, Norfolk, April 17, on "Conservative Treatment of Chronic Discharging Ears"—Dr Jesse L Bollman, Rochester, Minn, gave the semi-annual lectures before the Caducean Society of Creighton University School of Medicine, Omaha, May 3-4. His subjects were "Experimental Studies on Peptic Ulcer" and "Experimental Pathology of the Liver"

NEW YORK

Prize to Dr Ayer—The Merritt H Cash Prize of \$100 has been awarded by the Medical Society of the State of New York to Dr Wardner D Ayer, Syracuse, for his essay on "Spontaneous Subarachnoid Hemorrhage and Its Relation to the Aneurysm of the Circle of Willis" This is the sixth time the prize has been awarded, although it was established in 1863

Laboratory for Research in Physiology—The biological laboratory of the Long Island Biological Association at Cold Spring Harbor, L I, will open a new laboratory for research in general physiology, September 1, under the direction of Dr Eric Ponder, now professor of general physiology, New York University. The physiology laboratory will be in the George Lane Nichols Memorial, erected in 1928

Society News—Drs John C. A Gerster, New York, addressed the Norwalk Medical Society, May 9, on "The American Society for the Control of Cancer", Herbert R Charlton, Bronxville, N Y, on "Organization of a Tumor Clinic in a General Hospital", and George T Pack, New York, "A Plan of Radium Therapy for Small Hospitals"—Dr Henry Sage Fenimore Cooper, New York, addressed the Suffolk County Medical Society, West Islip, April 25, on acute conditions in the abdomen

New York City

Salmon Lecturer Chosen for 1935—Dr William Alanon White, superintendent of St Elizabeth's Hospital, Washington, D C, has been selected to deliver the Thomas W Salmon Memorial Lectures at the New York Academy of Medicine, April 12, 19 and 26, 1935. His subjects will be "Psychiatry as a Medical Specialty," "The Social Significance of Psychiatry" and "The General Implications of Psychiatric Thought"

Fellowship Available—The Women's Medical Association of New York City offers the Mary Putnam Jacoby Fellowship, \$1,000 for one year, available for graduate work in the medical sciences, to any woman graduate of an approved medical school. Applications for 1934-1935 should be filed with the secretary of the committee, Dr Rose Cohen, 36 West Ninetieth Street, by September 1, and accompanied by statements as to health, educational qualifications and proposed problem for investigation

In Memory of Dr Williams—The New York Academy of Medicine held a memorial meeting, April 26, for Dr Linsly R Williams, late director of the academy, who died, January 8. Dr Livingston Farrand, president of Cornell University, reviewed Dr Williams' life, John H Finley, Litt D, editor, the New York Times, and Dr John A Hartwell, present director of the academy, paid tribute to his achievements and influence. Dr Bernard Sachs, president of the academy, presided

Personal—Dr Albert A Berg was honored with a dinner, May 19, in observance of his retirement as attending surgeon at Mount Sinai Hospital after forty years' service.—The trustees of Johns Hopkins University and its medical faculty have selected Dr Simon Flexner, director of the Rockefeller Institute for Medical Research, to write the biography of the late Dr William H Welch.—Dr George W Kosmak has been elected chairman of the medical advisory committee of the Visiting Nurse Service, succeeding the late Dr Linsly R Williams. Two new members of this committee are Drs John Wyckoff, dean, New York University, University and Bellevue Hospital Medical College, and Marjorie Lord Strauss Knauth, who has been elected secretary.—Georgetown University, Washington, D C, conferred the honorary degree of doctor of laws on Dr Raymond P A Sullivan at its one hundred and thirty-fifth annual commencement, June 11

OHIO

Personal—Dr Frank H Lamb, who has been on leave of absence from the University of Cincinnati School of Medicine for several years, has been made professor emeritus.—Dr John H J Upham, Columbus, dean, Ohio State University College of Medicine has been reappointed as a member of the state medical board, to serve until 1941, this is his fourth

consecutive appointment.—Dr Wilbert A Hobbs, East Liverpool, was recently honored at dinner by physicians of Columbiana County, and of Hancock and Beaver counties, Pennsylvania, at Chester, Pa, in recognition of his fifty years in practice.—Dr Edgar J March, president of the staff at Aultman Hospital, Canton, was honored with a dinner, recently, celebrating the completion of fifty years in the practice of medicine

Dr Bruner Honored—The Cleveland Ophthalmological Society gave a banquet in honor of Dr William Evans Bruner, Cleveland, in recognition of his completion of forty years' service as ophthalmologist to the University Hospitals and to Western University School of Medicine. He was also presented with a pair of modeled book ends. Dr George W Crile was toastmaster, and speakers included Dr George E de Schweinitz, Philadelphia, a former teacher of Dr Bruner, Dr Walter R Parker, Detroit, a classmate, Charles F Thwing, LHD, president emeritus of the university, Dr Thorald Sollmann, dean of the medical school, and Frederick C Waite, PhD. A graduate of the University of Pennsylvania School of Medicine, Dr Bruner became affiliated with Western Reserve University School of Medicine as clinical assistant in ophthalmology in 1894. He has been professor since 1915

OKLAHOMA

Society News—At a meeting of the Woodward County Medical Society, Shattuck, April 10, speakers were Drs James Floyd Moorman, Oklahoma City, Roger L Hickman and Ellis Lamb, Clinton, on tuberculosis, Charles R Silverthorne, Wood ward, chest injuries, and Jesse J Davis, Higgins, Texas

State Medical Election—Dr Louis H Ritzhaupt, Guthrie, was chosen president-elect of the Oklahoma State Medical Association at its annual meeting in Tulsa in May. Dr LeRoy Long, Oklahoma City, was installed as president, and Dr Leonard S Willour, McAlester, was reelected secretary. The next annual session will be held at Oklahoma City

PENNSYLVANIA

Hospital News—Three Delaware County hospitals recently received appropriations from the county for care of the indigent. Chester Hospital received \$21,600, Taylor Hospital Ridley Park, \$7,080, and Delaware County Hospital Upper Darby, \$7,560. An additional appropriation of \$20,000 was made for the care of tuberculous patients through the Delaware County Tuberculosis Society

Philadelphia

New Society—The Philadelphia Metabolic Association was recently organized for interchange of modern conceptions of metabolism. At the first meeting, May 2, Dr Edward L Bortz presided and Dr Elliott P Joslin, Boston, gave an address on diabetes

RHODE ISLAND

Society News—The annual banquet of the Pawtucket Medical Society was held in Providence, March 15. Dr Stanley Sprague was toastmaster and the principal speaker, Prof James H Shoemaker, assistant professor of economics, Brown University, who discussed current events in Japan and Russia

Summer Round Up Omitted—The summer round up clinics for the examination of preschool children will not be held this year, in accordance with an agreement of the Providence School Department, the Parent-Teachers Association and the Providence Medical Association. Efforts will be made instead to have the children examined by their own physicians

TENNESSEE

Personal—Dr James C Gardner, Nashville, has been appointed physician to the Tennessee state penitentiary. Dr Theodore Morford will succeed Dr Gardner as physician to the Tennessee Industrial School. Dr Gardner succeeds Dr William Albert Sullivan

Health at Memphis—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million for the week ended June 9, indicate that the highest mortality rate (20.2) appears for Memphis, and that the rate for the group of cities as a whole was 11.4. The mortality rate for Memphis for the corresponding period last year was 16.5 and for the group of cities, 11.1. The annual rate for eighty-six cities for the twenty-three weeks of 1934 was 12.3 as against a rate of 11.7 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside

GOVERNMENT SERVICES

2123

the city limits or that they have a large Negro population may tend to increase the death rate.

Society News—Drs Buel L Ashmore and Joel J Hobson addressed the Memphis and Shelby County Medical Society, May 1, on pernicious anemia and vitamins, respectively. Among speakers at the semiannual meeting of the Middle Tennessee Medical Association in Springfield, May 10-11, were Robert William D Haggard, Lebanon, on cancer of the rectum, lymphangitis, and John R Gott, Murfreesboro, on bronchial asthma. Drs Carl W Brabson, Telford, and Edward T West, Johnson City, addressed the Washington County Medical Society, May 3, on "Diagnosis of Acute Indigestion and Appendicitis" and "Operative Results in Hernia," respectively. Speakers at the annual session of the West Tennessee Medical and Surgical Association in Jackson, May 10, included Drs Virgil E Simpson, Louisville, Ky, on diabetes mellitus and Horton R Casparis, Nashville, sequelae of the exanthems, and Richmond McKinney, Memphis, causes of esophageal stricture. Dr George A Brandon, Lexington, was elected president.

WEST VIRGINIA

Society News—Speakers before the Kanawha Medical Society in Charleston, May 8 were Drs Hugh G Thompson and Moritz F Petersen, on "Diabetes in the Adult" and "Diabetes in Children" respectively. At a meeting of the Central West Virginia Medical Society in Summersville, May 2, Drs Martin L Bonar Morgantown spoke on "Skin Troubles of Youth," and George F Grisinger, Charleston, on "Diagnosis and Treatment of Lner and Bile Tract Infections." Dr Richard O Rogers, Bluefield, presented a paper on "Agranulocytic Angina" before the joint meeting of the Mercer and McDowell County medical societies at Welch, May 9. Dr Howard G Weiler, Wheeling, discussed "Orthopedic Surgery for the Practitioner," at a meeting of the Marshall County Medical Society, April 17. Speakers before the Tyler-Wetzel Bi-County Medical Society in New Martinsville, May 11, were Drs Graver C Weil, Pittsburgh, and John P Henry, Pittsburgh on fractures and injection treatment of varicose veins, respectively.

WISCONSIN

Dr Miller Awarded Trudeau Medal—Dr William Snow Miller, emeritus professor of anatomy, University of Wisconsin School of Medicine, Madison, was awarded the Trudeau Medal of the National Tuberculosis Association at its annual meeting in Cincinnati, May 17, in recognition of his research in the anatomy of the lung and chest. Dr Miller graduated from Yale University School of Medicine in 1879. From 1889 to 1892 he served as pathologist to City and Memorial Hospitals in Worcester, Mass, and from 1882 until 1924 he was affiliated with the University of Wisconsin in various teaching capacities. He is the author of numerous papers on the anatomy of the organs of respiration, anatomic relations of pulmonary tuberculosis, anomalies of the pancreas and medical biography. Dr Henry Kennon Dunham Cincinnati, was elected president of the National Tuberculosis Association at this meeting.

GENERAL

Institute for Hospital Administrators—Lectures, round table discussions, seminars and conferences will make up the two weeks institute for hospital administrators in Chicago, September 10-22. Sessions will be held at Judson and Burton Courts dormitories of the University of Chicago. Information may be had from the executive secretary of the American Hospital Association, 18 East Division Street, Chicago.

Medical Bills in Congress—Changes in Status S 433 has passed the Senate directing the retirement of acting assistant surgeons of the United States Navy at the age of 64 years to permit the transmission in the mails of poisonous drugs and medicines to cosmetologists and barbers. H R 1766 has passed the Senate providing for retired employees of the United States disabled by injuries sustained in the performance of their duties such medical service as may be necessary on account of their injuries.

Dana Medal Awarded to French Ophthalmologist—The Leshe Dana Gold Medal awarded annually by the National Society for the Prevention of Blindness in cooperation with the St Louis Society for the Blind was presented to Dr Felix Joseph de Lapersonne, Paris at the meeting of the International Association for Prevention of Blindness in Paris May 14. Dr Lapersonne is president of the association of both the International Park Lewis Buffalo vice president of the national society and a former winner of the association and the national society.

the medal, made the presentation. Dr Lapersonne is the second European to receive the award, Dr Ernst Fuchs, Vienna, received it in 1929.

Society News—Dr George Gilbert Smith, Boston, was chosen president-elect of the American Urological Association at its annual meeting, June 1, and Dr Miley B Wesson, San Francisco, was inducted into the presidency. Dr Gilbert J Thomas, Minneapolis, was reelected secretary. At the annual session of the American Gynecological Society in May, Dr Brooke M Anspach, Philadelphia, was chosen president and Dr Otto H Schwarz, St Louis, reelected secretary. The next annual session will be held at Princeton, N J, Oct 21-23, 1935.

Association of Private Psychiatric Hospitals—The National Association of Private Psychiatric Hospitals was organized in New York, June 1, with Dr Hubert Work, formerly Secretary of the Interior of the United States, as honorary president of the American Psychiatric Association, and Dr John J Kindred, New York, as president. Other members are Drs Thomas P Prout, Summit, N J, vice president, Frank H Barnes, Stamford, Conn, assistant secretary, Dr James Percy Hickling and Walter Freeman, Washington, D C, the original incorporators, were elected honorary vice presidents. The purposes of the association, which has been incorporated under a federal charter in the District of Columbia, are:

The mutual protection of privately owned psychiatric hospitals and unity of action in all policies affecting the interests of private psychiatric hospitals to engage in the study of subjects pertaining to mental diseases and defects including the care treatment and promotion of the best interests of the insane epileptic and feeble-minded and allied cases to engage in foster and develop research for the advancement and furtherance of the knowledge of such subjects for the publication and to do any and all things necessary or desirable and in general to the association.

Homicides in 1933—A study of the death rates for homicide in 178 American cities for 1933 shows an average rate of 10.4 per hundred thousand of population, the same as in 1932. Lexington, Ky, had the highest rate 59.5 per hundred thousand, followed by Little Rock, Ark, with 52.5 per hundred thousand, with 50.8. Of the five largest cities, Chicago had the highest rate, 14.2, and the other cities were Detroit, 7.4, Los Angeles, 7.6, New York, 7.4, and Philadelphia, 6.7. All except Chicago showed decreases from 1932. Frederick L Hoffman, LL.D., consulting statistician, who prepared the report, found that in thirty-one cities for which figures since 1900 were available, the homicide rate has risen from 5.1 per hundred thousand in that year to 10.7 in 1933. Comparison with rates in other countries shows that the United States has the highest murder rate of any great civilized country. Other rates cited by Dr Hoffman are as follows: Germany, 2 per hundred thousand, Estonia, 6, France, 1, Greece, 5, England, Austria, 3, Portugal, 2, Sweden, 1, Switzerland, 2, Norway, 1, and Czechoslovakia, 3. Three factors contribute to this situation, in Dr Hoffman's opinion. They are possession of deadly concealable weapons on the part of the population distribution of crime literature and long drawn out criminal trials in which conviction takes place months after the crime or the criminal goes entirely free.

Government Services

Death of Dr Houck

Ulysses G Houck DVM, for thirty-eight years a member of the staff of the Bureau of Animal Industry, Department of Agriculture, and associate chief since 1928 died of Hodgkin's disease April 24 aged 68. For the past sixteen years Dr Houck had directed the division of foot-and-mouth disease control. During the 1924 outbreak of foot-and-mouth disease he was in charge of the federal and state forces that eradicated the disease. He is said to have been a pioneer in the organization of government meat inspection service. He was the author of a historical sketch of the accomplishments of the bureau.

Miss Abbott Resigns from Children's Bureau
Miss Grace Abbott for thirteen years chief of the children's bureau Washington D C has announced her resignation effective July 1. Miss Abbott will go to the University of Chicago to become professor of public welfare administration.

The Medical Service in the Army and Navy

As stated in previous letters, the pay of medical officers in the army and navy compared badly with the prospects of civilian practice, producing difficulty of recruitment. A committee was therefore set up by the government to investigate the causes of shortage of officers and nurses to make recommendations, which have now been adopted. The position of medical officers has been considerably improved, not by increasing the pay of the various ranks but by accelerating promotion and also lengthening the period of permanent commissions, so that men can retire at a higher rank than formerly and so qualify for a higher pension. This change is brought about by a short service system. In the army, all entrants will receive short service commissions and after five years will have the choice of retiring with a gratuity of \$5,000 or applying for a permanent commission. The result will be that officers in the permanent service will spend a greater part of their career in the higher ranks than formerly. An officer who joins at 25 and is granted a permanent commission is guaranteed that he will be a captain at 26 and a major at 35, instead of at 28½ and 37 as at present. Further, the career of a medical officer will be lengthened and will normally extend to the age of 57. The new rates of pay for the various ranks do not differ much from the old ones, being less in some cases and greater in others. They are lieutenant, \$1,780, captain, \$2,190, major, \$3,040, lieutenant colonel, \$4,670 (at the age of 42) and \$5,080 (at the age of 48), colonel, \$5,690. The number of specialist posts, which carry increased pay, has been increased.

In the navy, all entries will also be on a short service basis, preferably at the ages of 24 to 28, for three years, to be extended to five at the discretion of the admiralty. After three years, officers on leaving will be eligible for a gratuity of \$2,000 and, after five years for one of \$5,000. Transfer to the permanent list will be at the admiralty's discretion on completion of five years short service. A gratuity of \$5,000 will then be paid, but the officer will be required to render a minimum of twenty-five years' service in order to qualify for full pension. Officers retiring with less service will be entitled only to gratuities or retired pay reduced pro rata. The number of specialist posts carrying increased pay has been increased from sixty to eighty-three, and increased facilities are provided for postgraduate study. The age of retirement has been increased for surgeon commanders from 50 to 55 and for surgeon captains from 55 to 57. The number of surgeon captains has been increased from twenty to thirty-three.

Secret Drug Factories in the Near East

At a meeting of the League advisory committee on the traffic in opium and other narcotics, Russell Pasha, chief of the department of the Egyptian police for the control of drug traffic, said that in the last five years there had been improvement in Egypt in the control of narcotics. There was not so much smuggling of morphine, diacetylmorphine and cocaine from western Europe. These drugs now came principally from Greece, Turkey, Palestine, Syria and the Far East. There were also certain mysterious illicit centers in Turkey, some Bulgarian factories and a factory in the Far East. There were in Syria stocks of more than 8 tons of hashish. But it was Turkish and Bulgarian hashish that was most sought after. There was a strong demand for opium in Egypt but a law was about to be promulgated with regard to it. Russell Pasha

particularly drew attention to the situation in Bulgaria, where there are ten secret factories and the cultivation of opium has considerably developed. He was thanked for his voluminous report, which indicated the great and effective efforts made in Egypt to combat the scourge of drugs. Extraordinary revelations were made as to Bulgaria's activities. It was estimated that the illicit output of ten heretofore secret Bulgarian factories is not less than 3,000 Kg of diacetylmorphine, an amount twice that necessary for the medical requirements of the world and sufficient to poison 3 million persons. The United States delegate, Mr. Stuart Fuller, gave the result of recent investigations into the uses of acetic anhydride, which is used in the manufacture of certain dyestuffs, acetylsalicylic acid, rayon and diacetylmorphine. In a country that did not produce the first three substances it could be concluded that acetic anhydride was imported for the manufacture of diacetylmorphine. Investigations showed that in the last four years Bulgaria imported about 21,200 pounds of acetic anhydride, mostly from Germany, from which at least 10,600 pounds of diacetylmorphine could be manufactured. Russell Pasha stated that drug addiction did not exist in Bulgaria, but that the country was the one source in Europe of the wholesale manufacture of diacetylmorphine.

The Controversy About Pasteurized Milk

The controversy on the pasteurization of milk, described in previous letters, has been continued in the *Times*. A Bradford Hill, W. W. Jameson and W. W. C. Topley of the London School of Hygiene and Tropical Medicine reply to the argument that in a population of 9,000,000 children in this country under the age of 15 only about 4,000 cases of bovine tuberculosis occur annually, or one case in 2,200 children per annum. The proportion of children who eventually suffer must be much higher. It can be estimated that between one in 100 and one in 200 children develop the disease before the age of 15. Milk-borne diseases other than tuberculosis are by no means as negligible as the opponents of pasteurization state. Between 1912 and 1931 there were reported at least eighty-one outbreaks of various diseases due to milk. In 1929 there occurred a severe epidemic of septic sore throat involving more than 1,000 families, with sixty-five deaths, and in 1931 an outbreak of 312 cases of paratyphoid fever, with six deaths. Another sporadic infection due to milk is undulant fever.

Dr. L. H. D. Thornton, consulting pathologist, Wilts County Council, has found in his examination of children who have died from extraneous causes that at least 30 per cent show definite enlargement of the mesenteric glands. He has investigated these glands and found that their enlargement is due to living tubercle bacilli, though during life no ill effects are evident and many of these children are well nourished. These evidences of tuberculosis are present intermittently during childhood, the battle swaying to and fro, the glands sometimes enlarged and sometimes quiescent until eventually immunity is developed. Thus the great majority of infants are susceptible to bovine tuberculosis, while the great majority of adolescents are not. This development of immunity appears to be due to casual intermittent ingestion of tubercle bacilli. It may therefore be asked, Why sterilize milk? The answer is that in this rendering immune of the community a needless number will die. The susceptibility of certain children is due to several factors. But an additional factor is the massiveness of the dose. Thornton has found that the number of tubercle bacilli in infected milk varies enormously. The danger to the individual arises when a single cow happens to be excreting bacilli in enormous numbers. In the present state of knowledge, the only safe policy is to insist that milk shall not contain an undue proportion of tubercle bacilli. This can be done only by veterinary supervision or pasteurization. Thornton thinks

that it may be ultimately possible to supply a milk first sterilized by heating and then reinforced by vitamins and with some lowly strain of tubercle bacilli added, such as that used by Calmette, to produce immunity

Leprosy in Great Britain

Presiding at the annual meeting of the Home of St Giles for British lepers, the dermatologist Dr J M H MacLeod said that it was realized by few that cases of leprosy still occurred in this country. It was not possible to obtain exact figures, but estimates ranged from 50 to 100. The majority were persons who came from abroad with definite symptoms of leprosy or developed them later. There were also a few contact cases in which infection had occurred in this country, but none of these had been among those attending the patients. The Homes were dependent on voluntary contributions and received nothing from the government.

The Planning of Hospitals

An expert regional survey of the necessities of the country with regard to hospital accommodations has been made by a special committee of the Royal Institute of British Architects. The committee was appointed to submit evidence on the cost of hospital buildings to the Ministry of Health. It considers that by proper correlation of general and special hospitals, combined with an expert survey of town and country districts, much unnecessary expenditure might be saved and standardization in construction, equipment, and administrative services should result. The desultory rebuilding of hospitals on existing or adjacent sites is not always a practical proposition, and expert guidance should be readily available for hospital boards before large additional expenditure is incurred. Hospitals near one another should be asked to consider amalgamation, or at least the joint use of special departments.

The report endorses a recommendation of the British Subcommittee on Hospital Costing, presented to the International Hospital Association last June, that the hospital theater unit should be placed in one suite on the top floor of the building, and also the opinion that the sights and sounds of operations are not encouraging to other patients. Other points are as follows. No ward should contain more than sixteen beds. A day room with a sun balcony is essential. The psychologic effect of an open fire is urged by many physicians as of value in wards and day rooms. The matron should not have her suite of rooms in the nurses' home, for it is not part of her duty to police the nurses.

Tests for Automobile Drivers

The Committee of the House of Commons that is considering the road traffic bill discussed clauses dealing with disqualification of offending drivers. Sir Ernest Graham-Little (dermatologist) moved an amendment that an applicant for a driving license must pass a prescribed examination for fitness and subsequently a test of competence to drive. He described the results of researches by experts on accidents in factories that showed the importance of the human factor. This factor was as important on the road. The tests were to determine capacity to respond to an emergency, ability to judge distances and speeds accurately and rapidly, and vision. The technic of the application of the tests could be learned in two weeks and the tests could be applied by those experienced in driving.

Mr Stanley, minister of transport, said he was not in the least detracting from the value of the experiments already made or the possibility of better results in the future when he asked the committee not to accept the amendment. The experiments showed clearly the possibility of selecting the better drivers but the suggested tests would not enable one to determine whether a man who had not been in a car would be a safe driver. The Medical Research Council, after making

extensive experiments, informed him that the tests to distinguish between the good driver and the less good driver had proved useful, but that they did not determine whether a man was to be allowed to go on the road. He would continue to watch the future of the experiments. The amendment was negatived.

A University Department of Industrial Medicine

The specialization and increase of departments of medicine seem to have no end. The latest is the opening of a department of industrial hygiene and medicine in the University of Birmingham, which will take place October 1. The need has been felt for a university department that would undertake research in the application of medicine to industry and train physicians who are officers in industrial organizations or desire to qualify for these posts. The extraordinary variety of industries carried on in Birmingham render its university particularly suitable for this purpose. The injurious effects that may be produced on the workers by dust and emanations and by other causes, and their prevention, will be investigated. Physicians will be trained to advise employers as to the methods by which certain types of accident can be reduced, the best way of treating them and the selection of employees for the kind of work for which they are physically suited, and as to the improvement of the hygiene of factories. The university will probably institute a diploma in industrial hygiene.

The Robert Jones Memorial

A national memorial to Sir Robert Jones is being promoted by leading men in the medical profession and in public life. The president is Lord Derby, under whom, as minister of war, Jones rendered his services to the wounded. The memorial is designed to commemorate the life and example of one who became a national figure, one who, after centuries of ignorance, brought knowledge and devotion to the crippled child. It is also intended to sustain his tradition and to ensure, by research and adherence to his principles and ideals, the ultimate victory over the preventable and curable diseases, which should cease to add to the suffering of mankind. It is pointed out that to Jones is due the development of orthopedic surgery from a limited branch to one which during the war covered no less than 70 per cent of the surgical cases. The war gave him his great opportunity. He was in charge of no less than 33,000 beds and was the means of saving the empire a vast number of lives and preventing an enormous amount of crippling. After the war he organized the treatment of civilian cripples, both children and adults. The national memorial is to take the form of a Robert Jones professorship in the Royal College of Surgeons, a Robert Jones traveling fellowship, to be awarded alternately by the Royal College of Surgeons and by the University of Liverpool (the city where Jones practiced) and the Liverpool Medical Institute, a Robert Jones national trust, to ensure financial aid for orthopedic centers or institutions.

Tax on Insulin Removed

The protest aroused by the imposition of a 33 per cent tax on imported insulin was reported in *THE JOURNAL* April 7, page 1168. The scandal of this tax proved too much for it and the duty was removed almost as soon as it was passed. In the house of commons the minister concerned argued that duties did not mean an increase of price and pointed out that the price of British insulin had fallen since the imposition of the tax to 44 and 34 cents per hundred units in the case of two firms. It is now announced in the house of commons that the price of British insulin and of one brand of imported insulin has been reduced still further to 32 cents. The abolition of the duty has been done quietly, almost by stealth. *The Star*, which vigorously denounced the duty, emphasized the scandal that poor persons already handicapped by diabetes, should be compelled to pay more than is necessary for insulin.

Research on Various Metallic Bone Sutures

The variable results of suturing bones with metal devices have given rise to diverse interpretations. Rarefying osteitis often develops at the points of contact of wire and renders coaptation defective. Pseudarthroses may develop. That the toxic action of metals hinders the regeneration of the bone tissue cannot be doubted, for if the wire is removed in time the symptoms of necrosis cease. P. Menegaux, P. Moysé and D. Odiette have studied the effects of different metals on cultures of bone tissue and connective tissue *in vitro*, in accordance with the Carrel method. Menegaux and his co-workers used an 8-day-old chicken embryo; fibroblasts were obtained from a fragment of the heart, and osteoblasts from the leg bone. These were cultivated in chicken blood coagulated by a drop of extract of chicken embryo and containing the trephones indispensable for the maintenance of the culture. The tissue is cultivated at first for fifteen days, with successive transfers, in the incubator at a temperature of 38.5 C. At this time one secures pure cultures of both tissues. Later the cultures are placed in glass cupules with a metal disk on the bottom, and the experiments are continued. By measuring the rate of growth it is easy to follow the variations in the culture according to the metal employed, the examination being made with the microscope. Menegaux extended his experiments to twelve metals (iron, gold, copper, zinc, silver, aluminum, magnesium, lead, tin, nickel, tantalum and tungsten) and to twenty-one alloys, eight with an aluminum base, and thirteen varieties of steel. The metal disks were $10\frac{1}{16}$ mm in diameter and 0.25 mm in thickness and were obtained from a punching press. The results of these experiments were the following. The effects of a metal were exactly the same for the cultures of fibroblasts and of osteoblasts. The metals were divided, according to the results, into (1) very toxic, (2) slightly toxic and (3) indifferent. The very toxic metals arranged in descending order were copper, magnesium, iron, aluminum bronze and soft steel. The first two produce an immediate cessation of growth and cellular migration. After twenty-four hours, all transfers of cultures remain sterile. Magnesium dissolves gradually, with liberation of bubbles of hydrogen and the production of hydroxyl and magnesium carbonate. These salts, moreover, when employed alone, have the same inhibitive action on the cultures. In the rat, a disk of magnesium placed under the periosteum of a long bone creates a focus of necrosis. The other metals of this group (iron, aluminum bronze and soft steel) do not check growth entirely, although it is greatly retarded. The rate of growth is 150 times less than in the control cultures having no metal. It is evident, therefore, that soft steel wire and aluminum bronze wire are not suitable materials for bone sutures. In the second group (zinc, silver, tantalum, tin, nickel and tungsten) the toxicity follows in decreasing order as named. The rate of growth is about one-third that observed in the controls. In the third group are the harmless metals (gold, aluminum and lead) and the metal alloys. Duralumin appears to be the best adapted for bone sutures, as it has no action on the regeneration of the fibrous tissues, likewise the three moxidizable steels V2A extra, Nicral D and Platinostainless D are good. They do not inhibit the growth and the migration of osteoblasts and fibroblasts *in vitro*.

Deaths

Dr. Cazeneuve of Lyons has died at the age of 82. He had been professor at the Faculté de médecine de Lyon and was known for his research in organic chemistry and industrial hygiene. He was an associate member of the Académie of

Medicine. He was prominent also in politics. He became deputy and later senator for the district of Lyons and took an important part in the enactment of laws pertaining to hygiene. During the war he was called on to give advice in regard to explosives. His last researches dealt with the danger of using compounds with a lead or arsenic base as parasitocidal products in agriculture.

The death of Dr. Retterer, associate professor of histology at the Faculté de médecine de Paris, at the age of 88, is announced. He was the last surviving pupil of Mathias Duval and was the author of numerous histologic studies on hematopoiesis, odontogenesis, connective tissues, grafts of tissues and organs. He was a highly conscientious laboratory worker.

Dr. Octave Monod, surgeon to the Curie Radium Institute in Paris, has died suddenly at the age of 57.

Revision of Regulations Pertaining to Vaccination

The federal vaccination law of 1874 is to be revised. But as the revision cannot be completed before the beginning of the next vaccination period, the federal minister of the interior has requested the governments of the various *länder* to accept and apply in advance the new points of view of the vaccination problem concerning which there is essentially common accord. The main point is that in every case before vaccination is ordered an inquiry must be instituted to discover whether the person concerned can be vaccinated without endangering his health. In this revision of the vaccination law no provision is made for postponing vaccination for conscientious scruples. The new regulations provide that public vaccination shall be carried out in special vaccination centers. In place of four incisions, as formerly, now only two are made. Like wise the length of the vaccinal incisions has been changed. The former regulations established the length of the incision as up to 1 cm., but the new regulations provide for an incision only 3 mm. in length. The parents, foster parents or guardian of the vaccinated children may at any time consult the vaccinating physician and secure gratuitous advice in case, after the observation period, they note special manifestations in the persons vaccinated.

Health Insurance Associations (Krankenkassen)

For years there have been complaints that some members of the health insurance associations (*Krankenkassen*) unjustifiably use their insurance to make immoderate demands on the time of physicians. Various measures have been introduced to establish norms for the economical use of medicines. However, since the political upheaval, the chairman of the Allgemeine Ortskrankenkasse in Stuttgart has reported that an improvement in the morale of members of the *Krankenkassen* has been generally observed. The administrations of the *Krankenkassen* should show their appreciation of the improved attitude of the members. He pointed out that the insured members who still make unjustified demands on the *Krankenkassen* might be dealt with in a different way than in the manner heretofore in vogue. The Stuttgart local *Krankenkasse* has entered into an agreement with the larger industries to establish a closer relation between the local *Krankenkasse* and the various industries. According to this agreement, the head of the welfare service in each industry must constantly advise with the local *Krankenkasse* concerning the conditions affecting the members. He must inform the *Krankenkasse* when an industrial worker is in need of a rest cure or other prophylactic treatment, and he must report to the local *Krankenkasse* the names of persons who require special treatment.

The Piedmont Surgical Society

The Società Piemontese de chirurgia met recently in Turin under the chairmanship of Professor Uffreduzzi. Manca and Biolato spoke on postoperative thrombosis. On the basis of research on cadavers, the speakers hold that the frequency of venous thrombosis is due to retardation of the blood stream and particularly to the crossing of the left iliac vein by the right iliac artery and of the homolateral external iliac vein by the left hypogastric artery. The compression is favored by the projection formed by the fifth lumbar vertebra.

Gregoire, clinical surgeon of Paris, described the remote results of splenectomy in hemogenia. He stated that splenectomy is applied as a therapeutic intervention in accordance with the theory of Kaznelson, who regarded the diathesis as due to thrombopenia resulting from an exaggerated destruction of elements in the spleen. The observations of the speaker and of others have evidenced a rapid increase of the blood platelets within a few minutes of the intervention. Professor Gregoire emphasized the fact that the operation does not permanently cure the hemorrhagic diathesis, for while the platelets are temporarily increased they drop again to low figures, even below normal.

During the discussion, Professor Ceconi reported the history of a boy on whom splenectomy was performed by Professor Uffreduzzi more than eight years ago. He cast doubts on the belief of many others that the disease is of a constitutional nature. Because thrombopenia exists after the intervention, Professor Ceconi thinks that in these cases there is a peculiar fragility of the vessel walls.

Dr Griva obtained in a man, aged 26, no improvement from splenectomy. The case resulted fatally, and at necropsy an accessory spleen was found.

Professor Fasiano reported a cure of hemogenia, which had continued for more than six years.

Professor Morpurgo reported on 109 tumors of the thyroid examined histologically at the Centro tumori in Turin. According to the classification of Quervain and Wegelin, tumors were divided into colloid and cystic goiters, sixty, juvenile adenomas, eleven, colloid goiter (metastasis), one, proliferative langerhansian goiter, four, papillomatous adenoma, twelve, carcinoma, sixteen, and sarcoma, five. The small number of proliferative goiters was due to the fact that the plains and many valleys of Piedmont are immune to endemic goiter.

The Menace of Tuberculosis in Teachers

For years, a regulation has been in force allowing teachers affected with pulmonary tuberculosis to undergo treatment not exceeding two years in a sanatorium. In some instances teachers have resumed their positions before being cured, and in other cases teachers who were actually cured have not been allowed to return to their work.

Recently two new examples of bacillary infection among pupils have been traced to teachers. The children were subjected to a clinical and radiologic examination, and the results were startling. Sixty per cent of the children had evolutionary pulmonary tuberculosis, the incidence being particularly high in the lower classes. The teacher was in the habit of coughing and in the sputum were numerous tubercle bacilli. It might be alleged that this high percentage of tuberculous children was due to chance and not to contagion. However, the examinations showed in this instance that all the children were

affected with grave evolutionary tuberculosis. It was moreover, the gravity of the symptoms that attracted the attention of the attending physician and caused him to make an inquiry. Although all the circumstances seem to point to infection through direct contact with the teachers, the results of other inquiries must be awaited before any definitive conclusions can be drawn. The government has under consideration regulations requiring teachers to be examined from time to time. Those who are found to be ill will be admitted to a sanatorium for a period of from two to three years, for treatment. The detection of cases will be left to the school physician or to the consultation center of the district, where the teachers would be subjected to a radiologic examination. The teachers would be reexamined every year. Another prophylactic measure is needed, which consists in examining the children and the teachers before admission to a school.

Weil's Disease

Eijkel, the head of the public health service, has sent to physicians a circular letter dealing with the detection and treatment of Weil's disease. In 1932, 207 cases were diagnosed, sixteen of which proved fatal. On the appearance of the disease, one should use every endeavor to prevent toilet waters from being contaminated by the urine of rats. The minister of the interior has sent to the mayors of communes an official leaflet describing the measures to be taken. An early diagnosis is desirable, owing to the great chances of the success of serotherapeutic treatment instituted during the first few days. One should not await the results of the blood examination before giving an injection of serum. The serum, derived from the rabbit or the horse, may be secured in sufficient quantities from the Royal Institute of Serology in Utrecht. Horse serum is considered preferable, rabbit serum being reserved for patients who have already had injection of horse serum for other disorders. From 40 to 60 cc. is injected subcutaneously, the same dose may be repeated the following days. Afterward the treatment will consist in improving the diuresis by means of the dextrose-insulin method.

The Meat of Tuberculous Cattle

A supplementary memorandum concerning slaughtered tuberculous cattle has recently gone into effect. The whole carcass is destroyed if the animal had become much emaciated before being slaughtered. The meat is regarded as good after sterilization, when there appears to have been a recent infection or a localized focus. The glands and other localized areas of infection are excised and destroyed. The association of the directors of the communal abattoirs of the Netherlands adds that the animal will be discarded if there is disseminated tuberculosis in the muscles, which is found particularly after miliary tuberculosis or meningitis. According to Hoefnagel, one may regard tuberculosis as generalized when the organs that can be reached only by the greater circulation are involved.

The Medical Convention

At the Scientific and Medical Convention of the Netherlands, which opened under the chairmanship of Professor Van Uven, Prof. L. Bouman, the first speaker, discussed in a general way the subjects "biology" and "psychopathology." W. E. Hess described the sequels of epidemic encephalitis. Encephalitis causes disorders in the structure of the brain, and one can establish a connection between the structure and the psychic symptoms observed. The subjective symptoms should be established simply from the psychopathologic point of view. Dr. G. A. Kreuzwendedich von dem Borne gave the results of his research on Addison's disease. Using an extract of the suprarenal cortex, he secured good results. The dosage of the extract and the renal deficiency in Addison's disease were considered in detail.

Marriages

CLARENCE GEORGE OCHSNER, Wabasha, Minn., to Miss Anita Josephine Bouquet of Caledonia, June 9

STERRETT ERNEST DIETRICH, Ingram, Pa., to Miss Eleanor Elizabeth Carter of Allison Park, June 9

ROBERT B KARN JR., Clayton, Mo., to Miss Helen Marie Brueggeman of St Louis, April 21

EDWARD EISENBERG to Miss Charlotte Adland, both of Milwaukee, March 25

JAMES R DES PORTES to Miss Lila Parker, both of Fort Mills, S C, April 28

JOE THORNE GILBERT, Austin, Texas, to Miss Ailine Burch of Houston, April 12

JOHN EWING DUNN, Smithland, Ky., to Miss Louise Rouse in Paducah, April 20

CALVIN BASIL FAUSSET to Miss Helen Brooks, both of Indianapolis, May 20

JOHN K BULLOCK, Jackson, Miss., to Miss Mary Lewis Mayer, April 28

GEORGE W BEELER to Mrs Emma Graham, both of Seattle, April 28

Deaths

James Edwin Houghton ♂ Surg Lieut Commander, U S Navy, Washington, D C, George Washington University Medical School, Washington, 1917, entered the navy in 1917, fellow of the American College of Physicians, professor of hygienic and preventive medicine at his alma mater, 1924-1927, lecturer on tropical medicine, Jefferson and Hahnemann Medical schools, Philadelphia, 1931-1932 director of laboratories, department of sanitation and beneficence and medical director, National Leprosarium, Dominican Republic, 1921-1923, chief of the division of laboratories and instructor in tropical medicine and parasitology, U S Naval Medical School, aged 42, died, May 3

Seymour D Van Meter ♂ Denver, University of Pennsylvania School of Medicine, Philadelphia, 1889, formerly secretary of the state board of medical examiners, past president of the American Association for the Study of Gout and the Denver City and County Medical Society, aged 68 consulting surgeon to the Children's Hospital, Beth Israel Hospital and St Luke's Hospital where he died, February 27, of a malignant condition affecting the lumbar region of the spinal column

Edward Frederic Glaser ♂ San Francisco, Cooper Medical College, San Francisco, 1895, member of the Pacific Coast Oto-Ophthalmological Society for nearly eighteen years member of the state board of health for many years member of the board of directors of the National Association for the Prevention of Blindness, aged 68, died, May 9, in the Stanford Hospital, of lymphosarcoma

Elizabeth Delia Dixon Carroll, Raleigh, N C Woman's Medical College of the New York Infirmary for Women and Children, New York, 1895, member of the Medical Society of the State of North Carolina, professor of physiology and college physician to the Meredith College, aged 62, died, May 16, in a local hospital, of injuries received in an automobile accident

George Wood Harrison, Ashland, Wis., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1911, past president of the Ashland-Mayfield Iron Counties Medical Society, on the staff of the Ashland General Hospital and St Joseph's Hospital, aged 48, died, April 29, of cardiorenal disease

John Marsham Ropp ♂ Roanoke Va., Vanderbilt University School of Medicine, Nashville, Tenn 1891 University of Nashville (Tenn) Medical Department, 1891, aged 66 on the staff of the Roanoke Hospital, where he died, April 29, of spinal meningitis following injuries received in an automobile accident

Victor Mravlag, Elizabeth N J, University of Vienna Faculty of Medicine, Vienna Austria, 1872 member of the Medical Society of New Jersey formerly mayor of Elizabeth for many years head of the board of police commissioners at one time member of the board of health, aged 85, died May 15

Lewis Morgan Powell, Topeka, Kan University of Pennsylvania School of Medicine, Philadelphia, 1891, member of

the Kansas Medical Society, formerly professor of obstetrics at the Kansas Medical College, Medical Department of Washburn College, Topeka, aged 75, died, April 28, in Eustis, Fla

Solomon Metz Miller, Norristown, Pa., Jefferson Medical College of Philadelphia, 1902, member of the Medical Society of the State of Pennsylvania and the American Psychiatric Association, superintendent of the Norristown State Hospital, aged 68, died, May 24, of coronary thrombosis

Charles Lee Quaintance ♂ Queens Village, N Y, University of Virginia Department of Medicine, Charlottesville, 1921, on the staff of the Jamaica (N Y) Hospital, aged 39, died, April 10, in the New York Post Graduate Hospital, of pneumonia, following an operation for appendicitis

Abner Post ♂ Cambridge, Mass., Harvard University Medical School, Boston, 1870, professor of syphilology emeritus at his alma mater and the graduate school, for many years on the staffs of the Boston City and Children's hospitals and the Boston Dispensary, aged 89, died, April 20

Edward Hyatt Hutton ♂ Corning, N Y, Columbia University College of Physicians and Surgeons, New York, 1900, fellow of the American College of Surgeons, served during the World War, attending surgeon to the Corning Hospital, aged 61, died, May 7, of influenza

John C Doolittle ♂ Lancaster, Wis., Wisconsin College of Physicians and Surgeons, Milwaukee, 1907, past president of the Grant County Medical Society, member of the school board, medical director and owner of a hospital bearing his name aged 50, died, May 20

Gilmer H Moore ♂ Opelika, Ala., Maryland Medical College, Baltimore, 1904, past president and secretary of the Lee County Medical Society, served during the World War on the staff of the East Alabama Hospital, aged 54, died, April 13, of peptic ulcer

Oleander Howton, Luxora, Ark., Hospital College of Medicine, Louisville, Ky., 1903, member of the Arkansas Medical Society, served during the World War, aged 56, died, May 7, in the Methodist Hospital, Memphis, Tenn., of pneumonia

E S H McCauley ♂ Beaver, Pa., Cleveland Medical College, 1897 past president of the Beaver County Medical Society, on the staff of the Beaver Valley General Hospital, New Brighton, aged 61, died, April 30, of pulmonary embolism

Richard Russell, Arvada Colo., Gross Medical College, Denver, 1900 county health officer, formerly mayor of Arvada, for many years president of the board of education, aged 69, died, April 12, in St Luke's Hospital, Denver, of pneumonia

Eli Crawford Boyette, Charlotte, N C, Baltimore Medical College, 1893, veteran of the Spanish-American War, aged 66, died, May 13, in the Veterans' Administration Facility, Oteen, of chronic pulmonary tuberculosis

Alice Gertrude Symonds Churchill, Darling Lake, N S, Canada Tufts College Medical School, Boston, 1899, formerly on the staff of the Hale Hospital Haverhill, Mass., aged 73, died, May 14, in a hospital at Yarmouth

William Albert Kirksey, Hope Mills, N C, Washington University School of Medicine, St Louis, 1921, member of the Medical Society of the State of North Carolina, aged 44, died suddenly, May 1, of heart disease

Edward Roswell Newton ♂ Boston, Harvard University Medical School, Boston, 1898, member of the New England Otological and Laryngological Society, served during the World War, aged 59, died, May 18

William Johnson, London, Ky Tennessee Medical College Knoxville 1896, member of the Kentucky State Medical Association member of the county board of education aged 65 died, April 23, of heart disease

Emil Ernst Hartman ♂ Anthony, Kan., Washington University School of Medicine, St Louis 1925, formerly secretary of the Harper County Medical Society, aged 35, died, April 21, of heart disease and influenza

William Ambrose Cahill ♂ Huntington Park, Calif., Dartmouth Medical School, Hanover N H, 1894, member of the Medical Society of the State of New York, aged 73, died, May 28, of arteriosclerosis

Prince Albert Melick ♂ Williams, Ariz Beaumont Hospital Medical College, St Louis 1892 physician and owner of the Williams Hospital aged 64, died, April 16 in the Santa Fe Hospital, Los Angeles

Richard C Burton, Savanna, Ill., Bennett College of Eclectic Medicine and Surgery Chicago 1878 for many years health officer aged 84, died, May 4 of abdominal carcinoma and arteriosclerosis

Hubert Rogers Kannenberg, Dallas, Texas, Baylor University College of Medicine, Dallas, 1930, member of the State Medical Association of Texas, aged 29, died suddenly, May 7, of angina pectoris

Charles Sumner Webber @ Weymouth, Mass., Boston University School of Medicine, 1926, instructor in clinical pediatrics at his alma mater, aged 36, died suddenly, May 16, of heart disease

Charles Clyde Tellesen @ Wynot, Neb., Rush Medical College Chicago, 1909, veteran of the Spanish-American War, aged 58, was killed, May 5, of injuries received in an automobile accident

Howard Fitzgerald Clark, Syracuse, N. Y., Syracuse University College of Medicine, 1899, member of the Medical Society of the State of New York, aged 59, died May 4, of heart disease

George Lee Eaton @ San Francisco, Vanderbilt University School of Medicine, Nashville, Tenn., 1894, member of the American Urological Association, aged 61, died, April 25, of heart disease

Hanson Slaven Ogilvie, Asheville, N. C., Medical College of Virginia, Richmond, 1909, member of the Medical Society of the State of North Carolina, aged 50, was found dead, March 22

William McK Housman, Sioux Falls, S. D., Cincinnati College of Medicine and Surgery, 1877, member of the South Dakota State Medical Association, aged 80, died, May 17, of angina pectoris

George Hill Christy @ Vernal, Utah, Denver College of Medicine 1900, past president and secretary of the Uinta County Medical Society, aged 57, died, May 16, of coronary thrombosis

Dudley Henry Morris, University, Va., Columbia University College of Physicians and Surgeons, New York, 1909, aged 49, died, March 29, in a local hospital, of bronchopneumonia

Elmer Le Roy Biggs @ Los Angeles, Dunham Medical College, Chicago, 1901, aged 59, died, May 6, in the Good Samaritan Hospital, of bronchopneumonia and cirrhosis of the liver

Curtis B. Pendleton, Markleville, Ind., Physio-Medical College of Indiana, Indianapolis, 1892, aged 80, died, April 17, of purpura hemorrhagica and acute dilatation of the heart

Elisha William Lister, Elizabeth City, N. C., Medical College of Virginia, Richmond, 1896, member of the Medical Society of the State of North Carolina, aged 62, died, May 1

Harold York Masfield, Columbus, Ohio, Ohio Medical University, Columbus, 1900, member of the Ohio State Medical Association, aged 54, died, May 3, of chronic myocarditis

Granville A. Richart, Blackburn, Mo., University of Louisville (Ky.) School of Medicine, 1886, member of the Missouri State Medical Association, aged 73, died, May 3

Henry William Albers, Terrace Park, Ohio, Cincinnati College of Medicine and Surgery, 1882, formerly member of the board of education of Cincinnati, aged 76, died, May 6

Julia Ross Low, Detroit, Chicago Homeopathic Medical College, 1880, Harvey Medical College, Chicago, 1895, aged 78, died, May 24, of arteriosclerosis and chronic myocarditis

La Fayette Seal, New Tazewell, Tenn., University of Tennessee Medical Department, Nashville, 1891, aged 70, died suddenly, May 11, of heart disease, in a theater at Knoxville

Theodore F. Johnson, National City, Calif., Chicago Medical College, 1877, formerly county coroner, for many years school trustee, aged 82, died May 2, of heart disease

Arnold Paige @ Erie, Pa., University of Buffalo School of Medicine, 1927, aged 32, died March 8 at the Jefferson Hospital, Philadelphia of adenocarcinoma of the stomach

Michael Horatius Couture, Lynn, Mass., School of Medicine and Surgery of Montreal, Que., Canada, 1893, aged 69, died May 16, of cerebral hemorrhage and arteriosclerosis

Charles E. Menard, Pacific Kan., Kansas Medical College Medical Department of Washburn College, Topeka, 1898, aged 65, died, May 1, of chronic valvular heart disease

Harry Izner, Chicago, Chicago College of Medicine and Surgery, 1912, member of the Illinois State Medical Society, aged 48, died, May 24, of carcinoma of the esophagus

William Littlefield Ripley, Boston, Tufts College Medical School, Boston, 1903, member of the Massachusetts Medical Society, aged 62, died May 1 of heart disease

Francis Jewell Crane, Tonopah, Nev., Chicago Medical College, 1879, member of the Nevada State Medical Association, aged 79, died May 4 in a local hospital

Ralph Whitney Reynolds, Pasadena, Calif., Cleveland Homeopathic Medical College, 1902, member of the California Medical Association, aged 64, died, April 19

James Caldwell Price, Toledo, Ohio, Cleveland Homeopathic Medical College, 1903, aged 64, died, April 22, in the East Side Hospital, of cerebral hemorrhage

Charles William Espy, Chicago, Rush Medical College, Chicago, 1892, member of the Illinois State Medical Society, aged 70, died, May 22, of lobar pneumonia

Charles Henry Hall, Monroe, N. Y., College of Physicians and Surgeons, Baltimore, 1891, aged 72, died, April 19, of chronic myocarditis and arteriosclerosis

Clarence Howard Waite, Pittsfield, Mass., Bellevue Hospital Medical College, New York, 1885, also a druggist, aged 75, died, April 20, of chronic myocarditis

George Alvin Cassidy, Fremont, Neb., McGill University Faculty of Medicine, Montreal, Que., Canada, 1885, aged 76, died, May 18, of coronary thrombosis

William David O'Byrne @ Chicago, Rush Medical College, Chicago, 1899, veteran of the Spanish-American War, aged 72, died, May 25, of pneumonia

Conway Bates, Ironton, Mo., St. Louis Medical College, 1883, member of the Missouri State Medical Association, aged 77, died, May 2, of pneumonia

Henry Mercer Richards, Lakeland, Fla., Atlanta (Ga.) School of Medicine, 1909, member of the Florida Medical Association, aged 54, died, April 6

Anna J. Fronk-Srom, Chicago, College of Medicine and Surgery, Chicago, 1903, aged 73, died May 11, of pneumonia, diabetes mellitus and hypertension

William Addison Smith, Ithaca, N. Y., Long Island College Hospital, Brooklyn, 1889, health officer of Newfield, aged 67, died, March 31, of carcinoma

Homer John Hall, Franklin, Ind., University of Louisville (Ky.) School of Medicine, 1877, aged 82, died, April 29, of acute nephritis and influenza

William R. Terry, Shellman, Ga., Atlanta Medical College, 1890, member of the Medical Association of Georgia, aged 71, died, February 14

William Prentice Knox @ Alcoa, Tenn., Vanderbilt University School of Medicine, Nashville, 1931, aged 29, died, May 6, of acute uremia

Anthony Domenick Tarditi, New York, Columbia University College of Physicians and Surgeons, New York, 1903, aged 54, died, April 5

Wilmot Charles Willits @ Kansas City, Mo., University Medical College of Kansas City, 1901, aged 68, died, May 1, of coronary occlusion

Artemas Brown, Berwyn, Ill., College of Physicians and Surgeons, Keokuk, Iowa, 1887, aged 74, died, April 28, of chronic myocarditis

Anna Albers, Chicago, Illinois Medical College, Chicago, 1908, aged 70, died, May 29, of septicemia, otitis media and diabetes mellitus

Arthur C. Hutchins, Des Moines, Iowa, Drake University Medical Department, Des Moines, 1905, aged 70, died, April 24, in Van Meter

William Howard Ensworth @ Boston, Harvard University Medical School, Boston, 1888, aged 68, died, May 3, of pulmonary embolus

Percy Vernon Ellis, Ghent, Ky., University of Louisville School of Medicine, 1886, aged 69, died, May 1, of cerebral hemorrhage

Ada Carr, Paterson, N. J., New York Medical College and Hospital for Women, 1882, aged 81, died, May 17, of bronchopneumonia

Francis M. Gage @ Shelton, Wash., Atlanta (Ga.) Medical College, 1895, aged 60, died, April 29, of carcinoma of the prostate

Willis H. Davis, Peoria, Ill., College of Physicians and Surgeons, Keokuk, Iowa, 1879, aged 81, died, May 9, of heart disease

John Willis Baldwin, Arthur, Tenn. (licensed in Tennessee in 1889), aged 77, died, May 10, of disease of the prostate gland

Gioacchino Stabili, Morrisville, Pa. (licensed in Pennsylvania in 1911), aged 71, died, February 7, of arteriosclerosis

Will W. Tyson, Perry, Fla., Atlanta Medical College, 1889, aged 68, died April 1 of pneumonia

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

RAGWEED SEASON IN THE WEST

To the Editor—I am seeking information and wonder if you could help me. I have a patient who suffers from ragweed hay fever. The season begins here about August 15. She is planning a trip to California, starting the first of June. She has not been immunized. Is there a ragweed season starting earlier in the West? What difficulties would she be likely to encounter in this regard?

ALBERT B. HONGMAN, M.D., Kalamazoo, Mich.

ANSWER—The North Pacific Coast (Portland and Seattle) is entirely free from ragweed pollen at all seasons. Western ragweed and certain species of false ragweed begin to pollinate in the Southwest as early as May 15, but in most places in the West not before July 1 or later. Exposure to ragweed pollen is therefore possible in the West and Southwest many weeks before the usual ragweed season in Michigan, but the probability of exposure for one engaged in ordinary pursuits is slight. Present records indicate that the total amount of ragweed pollen encountered in central and southern California and Arizona during the whole summer and fall is much less than that encountered on an average day during the ragweed season

Ragweed Season 1933

	Date of Onset of Ragweed Season	Maximum Ragweed Concentration Pollen per Cubic Yard of Air	Date of Maximum Concentration	Total Seasonal Fall of Ragweed Pollen on Area of 18 Sq. Cm.
Detroit	Aug. 12	1,932	Sept. 6	8,011
Chicago	Aug. 12	840	Sept. 1	7,249
Denver	Aug. 10	363	Aug. 26	3,804
Salt Lake City	Aug. 14	91	Sept. 2	252
Bolse Idaho	Aug. 15	36	Sept. 29	209
Spokane Wash		2	Aug. 18	8
Seattle (1929)		0		0
Portland Ore		0		0
Reno Nev		4	Sept. 5	12
Sacramento Calif		7	Sept. 17	34
Los Angeles		14	Sept. 8	144
Phoenix Ariz	May 15	12	Oct. 21	145
Roswell N. M.	Aug. 15	44	Sept. 25	350

in Michigan. On May 15 the average ragweed pollen content of the air in southern Michigan is at least 15 granules per cubic yard of air. If a concentration as high as this has ever been found in California, it has not been reported. The statistics for 1933 in the accompanying table may be useful in deciding the patient's itinerary.

TRAUMA AND ALLERGY

To the Editor—A man, aged 45, was struck on the head with a black jack in a holdup May 30, 1933, sustaining a concussion of the brain. Headaches lasted for about two months and then abated. August 25 he developed typical but severe symptoms of hay fever for the first time in his life. Skin testing revealed that he was sensitive to ragweed. The symptoms of vasomotor rhinitis continued with their initial severity into the fall and winter and further skin testing then showed that he was sensitive to feathers and dust. The amount of relief obtained so far from injections of ragweed feathers and dust has been unsatisfactory, as he still suffers from constant nasal congestion. Any suggestions you can offer as to further treatment will be appreciated. Is there anything in the literature indicating that trauma of the type described can bring out a latent allergic state? I have not been able to find this out in my own reading. Please omit name.

M.D. New York

ANSWER—A search of the literature reveals no instance wherein trauma can be blamed for the onset of allergic symptoms, e.g., hay fever or asthma. An excessive exposure to pollen as in going to camp during a pollinating season can and often does exceed the threshold of the potential allergic with resultant symptoms. But trauma is not a cause except that it might act by lowering the general resistance.

Complete skin tests, if not already done, should be carried out for pollens, epidermals, foods and miscellaneous substances, e.g., cottonseed and orris root. Desensitization should be attempted by injecting against ragweeds and house dust. Feathers should be eliminated and the premises kept as free from dust as possible.

The constant nasal discharge calls for a thorough nose and sinus examination, perhaps with x-rays. The nasal discharge should be examined for eosinophilia by fixing on a slide and staining with Wright or other similar stain. Allergy would be definitely indicated if the proportion of eosinophils exceeded 10 per cent, such smears frequently show over 50 per cent.

Finally, if specific treatment by ragweed and dust extracts is unsuccessful, nonspecific measures should be tried, in succession, if necessary. Among such methods may be mentioned the use of vaccine, stock or autogenous, ultraviolet radiation, x-rays, injections of foreign protein, e.g., sterile milk, also autohemotherapy.

VACCINATION AGAINST CANINE RABIES

To the Editor—In *Queries and Minor Notes* (THE JOURNAL, April 7, p. 1180) you state that there are no available data as to the efficacy of the prophylactic vaccination of dogs against rabies under field conditions. This is a very vital matter, as such vaccination has been required by the state of Washington since 1932 in certain counties where rabies in dogs has been endemic. Two dogs in Seattle have become rabid within a year after a single required vaccination (from 3 to 10 cc of phenol-treated virus); the last case having occurred five months after vaccination. The immunity afforded by this single vaccination is supposedly one year as you note. Since from fourteen to twenty-eight injections of rabies vaccine are required to produce immunity against rabies in man and this protection lasts only a year, the single injection used for canine immunity would seem a priori to be absurd. Even if the protection afforded by a single injection of vaccine against rabies in the dog were efficient, this method in practice would be most unsatisfactory. It is impossible to get dog owners to vaccinate more than a fraction of their animals. The careless and irresponsible ignorant owners of dogs are the very ones who neglect vaccination and when the period of supposed immunity has elapsed few owners have their dogs revaccinated. It is also often uncertain whether dogs have been vaccinated or not, as the animals often lose their tags. Cases of rabies in dogs have continued hereabouts during the period of vaccination. Some 132 cases of ascertained rabies in dogs have occurred in Seattle and vicinity since 1932 and about 5,000 dogs have been vaccinated in the same area during this period. Recently the health authorities have gone back to the old method requiring dogs to be muzzled or leashed and ordering dogs not so cared for to be picked up by the police. You would indeed render a valuable service if you could supply some experimental evidence concerning the single prophylactic vaccination of dogs against rabies. If there is no such evidence available as you say, this method appears to be a very dangerous and unscientific mode of protection for dogs or man against this invariably fatal and horrible disease to be officially adopted by government authority. Would you kindly express your opinion freely on this important matter?

KENELM WINSLOW, M.D., Seattle

ANSWER—From the statements in this communication there does not seem to be any question about the inadequacy of the preventive measures against canine rabies as practiced in the state of Washington at present. The experimental work on vaccines against canine rabies is reported by Schoenning, H. W. Experimental Studies with Killed Rabies Vaccines, *J. Am. Vet. A.* 76:25 (Jan.) 1930. Prophylactic Vaccination of Dogs Against Rabies, *ibid.* 78:703 (May) 1931. These articles contain the reports on work carried out in the Pathological Division, Bureau of Animal Industry, U. S. Department of Agriculture. As vaccination against rabies still is in the experimental stage, there must be no relaxation but rather increasingly effective enforcement of the essential, standard control methods of licensing, quarantining, and the impounding and destruction of stray dogs. The experience in England and the Scandinavian countries shows that canine rabies can be controlled and eradicated by such methods.

TREATMENT OF SNAKE BITE

To the Editor—Would you kindly inform me if the following procedure is still advocated in a case of snake bite (quotation from handbook for boys Boy Scouts of America). Quickly make the wounds bleed by opening each fang hole with an x-shaped cut made by a sharp knife. Please omit name and address.

M.D. Iowa

ANSWER—The first thing to do is to apply a tourniquet above the snake bite if it is on the extremity so that this is possible.

The wound should be cut open at once with a crucial incision, some of the tissue may even be cut out if done by a physician, and suction applied.

The tourniquet should be loosened for a few seconds every five minutes so as not to interfere too much with the circulation, and this also permits the venom to pass slowly into the system. This procedure should be kept up for an hour or more.

Alcohol is injurious after snake bites.

The venom has little effect when swallowed.

The injection of a solution of chlorinated soda into and around the site of the bite will diminish the toxicity of the venom. Also the injection of the salts of gold, mercury and zinc around the wound have given better results than permanganate or other oxidizing agents. They must be injected

before a lethal dose has entered the system, but if given in too large doses they may do harm by increasing tissue necrosis. A polyvalent serum against the rattlesnake, copperhead and water moccasin has been accepted by the Council on Pharmacy and Chemistry. It should be injected at once or within twelve to twenty-four hours if possible. Part of the serum should be injected around the bite and the remainder higher up under the skin and in the muscle. If the patient is not better within four hours, the injection should be repeated. Ammonia water given subcutaneously is of value in doses of from 1 to 2 cc to control shock, but other stimulants also may be given.

DECAY OF TEETH AND CALCIUM METABOLISM

To the Editor—A girl aged 15 years apparently has been on a perfectly well balanced diet all her life and the blood calcium at this time is 11.1. In the last six months several of her teeth have become decayed and the enamel on her teeth is thinning out and losing its lustre. Her dentist thought that she probably had some calcium deficiency, but her diet is adequate and a check up on the blood calcium proves that it is within normal limits. This is the second patient that I have had in this territory in the last two or three years with this complaint and I am wondering whether you can give me any light on the question.

E. M. KERSTEN M.D. Fort Dodge Iowa

ANSWER—The age of the patient is that of one of the periods of greatest susceptibility to dental decay coincident with rapid growth and general readjustment of metabolism. A blood calcium of 11.1 mg per hundred cubic centimeters of blood plasma is within the normal range, though toward the high side. This may be deceiving, as it is no assurance of a positive calcium balance, since the level of the blood calcium is presumably controlled by the parathyroid secretion and this favorable blood picture may be preserved by an active parathyroid depletion of the calcium reserves in the bones rather than by ingestion from the gastro-intestinal tract. The high calcium level of the blood is rather suggestive under these circumstances of just such a condition. It is possible even with a "perfectly well balanced diet" that mineral metabolism is faulty and that absorption of calcium from the food is not proceeding rapidly enough to balance the demand for calcium for growth and that lost through elimination. In spite of many assurances to the contrary it is debatable as to just how much this and similar cases may be benefited immediately by treatment, since the etiology of dental caries is not wholly clear. Because of great susceptibility to decay extraordinary precautions should be taken, frequent visits to the dentist and prompt filling of each cavity in such a way as to inhibit local recurrence, vigorous use of the mouth in chewing careful attention to brushing the teeth each time after eating and a diet well fortified with minerals and vitamins are recommended. Carbohydrates should be reduced to a level barely sufficient for energy requirements.

NONSURGICAL TREATMENT OF SENILE HYPERTROPHY OF PROSTATE

To the Editor—Is there any nonsurgical treatment that would be of benefit in cases of senile hypertrophy of the prostate or of its prominent symptoms of increased frequency of urination and especially nocturia? In other words is there anything that might be of benefit in some cases of hypertrophied prostate in the use of drugs heat or cold diathermy massage, ultraviolet or electricity? Please omit name.

M.D. Virginia

ANSWER—The use of heat, drugs and massage has a definite place in the treatment of senile hypertrophy of the prostate. These forms of treatment are only palliative. They are never curative. Many times they relieve frequency of urination, burning and pain. The massage treatments should be carried out about once or twice a week, depending on the amount of pus present in the strippings and also on the amount of relief the patient obtains from the massage. The massage should be done carefully and gently, the production of pain being avoided, with avoidance also of blood at the external urethral orifice after massage. Heat may be used through one of the various instruments designed for that purpose either through a prostatic tube or by means of an electrical prostatic heater. Patients are generally more comfortable and obtain more relief from heat than they do from applications of cold. Diathermy has not proved very satisfactory. Many patients obtain relief from this program. On the other hand the patient with senile hypertrophy of the prostate who has symptoms is headed for surgical relief and this may be obtained in a relatively simple way by means of a transurethral electrical resection. This new method carries with it an exceedingly low mortality rate and the period of hospitalization is short, varying from five to eight days.

One might be justified in advising the patient to use heat and massage for a period of three months, or perhaps six months, and if the desired relief is not obtained he should have a transurethral electrical resection of the prostate.

DIAGNOSIS OF SYPHILIS AND SYPHILOPHOBIA

To the Editor—A dentist gives a history of an innocent infection of his finger with a two plus Wassermann reaction about eighteen years ago. He received four or five injections of arsphenamine (or neo arsphenamine) and four or five gluteal injections of corrosive mercuric chloride. He also took some mixed treatment orally for a while. Blood Wassermann tests made annually since that time have remained negative. He lives in fear of tertiaris developing although so far he has apparently been in good health. He refuses a spinal test. Kindly let me know whether he can be considered cured or what the chances are of his developing tertiary symptoms. He is about 43 years of age. Please omit name.

M.D. New York

ANSWER—The diagnosis in this case is open to criticism for one two plus Wassermann reaction is an entirely inadequate basis for a diagnosis of syphilis. Even a strong positive result would require repetition if the diagnosis had to rest on the Wassermann reaction. If repeated tests show weak or doubtful reactions, the case should have been observed for a time in expectation of further clinical evidence. At the present time, however, it would be a great injustice to the patient to admit any doubt of the diagnosis. He must be considered to have had syphilis and suspected of still having it. It is imperative that a thorough clinical examination of the central nervous system be made, with a careful study of the spinal fluid, to rule out the possibility of hidden infection. In spite of the repeatedly negative blood tests, a general physical examination with particular attention to the possibility of syphilis, should also be made. If no evidence of syphilis is found, he may be considered cured.

This may not satisfy his fears, for a man of medical education who fears tertiary involvement and yet refuses a spinal fluid test cannot be considered normal mentally but must be classed as having syphilophobia. Mental treatment is needed. These cases are hard to handle. If nothing else succeeds it may be permissible in some cases to give a mild course of iodides with mercury or bismuth preparations with the understanding that this treatment is given solely for its mental effect.

TREATMENT OF DEMENTIA PARALYTICA

To the Editor—A man aged 39 married but separated from his wife and in excellent physical condition has had syphilis for at least ten years. Four years ago mental symptoms appeared. Antisyphilitic treatment was begun in the summer of 1930. During this treatment the patient had to be institutionalized for his mental condition. At that time the blood Wassermann reaction was 4 plus and the spinal fluid showed marked traces of globulin 12 cells and a trace of dextrose. The Wassermann reaction with 0.2 0.4 0.6 and 0.8 cc was negative. The colloidal gold test was 4444322000. The gum mastic test was positive. The Takata-Ara test was positive. Malaria was given and the patient had eight chills. He improved both mentally and physically during his stay at the institution. In November 1930 a tryparsamide course was begun in May 1931 the blood Wassermann reaction was 3 plus with noncholesterolized antigen and 4 plus with cholesterolized antigen. The same month a second course of tryparsamide was begun. The blood Wassermann reaction in October 1932 was 1 plus with noncholesterolized antigen and 3 plus with cholesterolized antigen. The patient was given in January 1934 a third course of tryparsamide. The treatment was discontinued after 10 Gm was given because ophthalmoscopy which the patient allowed for the first time revealed a pale left eyeground with a somewhat paler optic disk. The patient cannot discern the number of fingers held before his left eye. The right eye is still fairly good. I should like to know what in your opinion is the proper course of treatment to follow. His condition at present is very good physically. Mentally he has been improving at a rate and somewhat weakened. The left arm and leg are very ataxic and somewhat paralyzed. The right arm and leg are very ataxic and somewhat paralyzed. In view of the fact that the alaxia seems to be getting worse. It is possible that the completion of the third course of tryparsamide may cause a loss of vision in the right eye. The patient will not allow proper examination so that the optic disk in the right side cannot be seen. The patient is still institutionalized and can be kept in bed as long as is necessary. What treatment do you advise? Kindly omit name.

M.D. New York

ANSWER—Obviously the outlook for the patient is not good, as he has had considerable treatment without complete recovery. One would suppose that the probabilities are that he has reached the maximum of improvement possible. At any rate one is certainly not able to use any of the arsenicals with any degree of safety. Possibly some further indication as to the outcome could be obtained from examination of the cerebrospinal fluid at the present time. Should this be negative one

would have good evidence to assume that treatment could accomplish but little. If, on the other hand, it should be strongly positive, one would feel that fever therapy was the only available therapy that could be given, either in the form of another course of malaria or by diathermy.

URTICARIA HIEMALIS

To the Editor—About two months ago while riding on a railroad velocipede in the open I noticed a rather marked symmetrical swelling of all the fingers. This subsided after three or four hours in a warm room. The swelling appeared like the wheals in urticaria being red at first and then blanching. There is some burning and itching of the parts exposed to the cold wind. When I take a piece of ice in my hand an urticarial-like lesion appears promptly. Now the swelling appears in the ears, the face or any part that is exposed. At present there is slight tingling in the fingers. My general health is excellent and no other symptoms are noted. Exposure to cold has been less this winter than ever before. By wearing warm gloves and rubbing my hands often I can prevent the condition in my hands. I am guessing that this is a case of cold allergy. Will permanent enlargement of the parts be likely if the lesions are caused to appear two or three times each day? Is there any cause for cold allergy besides exposure to cold? What is the treatment if any other than change to a warm climate? In my work I travel on an open railroad velocipede each day and prevention of exposure of some parts to cold wind is almost impossible. Would a focus of infection in the appendix or prostate be likely to influence the condition?

WILLIAM S. HARGAN, M.D., Worley, Ky.

ANSWER—The case here described is a typical case of contact allergy caused by cold, described by Duke as urticaria hiemalis (Urticaria Caused Specifically by the Action of Physical Agents, *THE JOURNAL*, July 5, 1924, p. 3).

Repeated reaction in the hands and face, caused by exposure to cold, will cause in the course of time organic changes in the skin. Exposure of a large part of the body to low temperatures, especially between 5 and 15 C., can cause a dangerous or even fatal reaction. Such a reaction could be encountered on a motorcycle trip when the outside air is at the temperatures mentioned or by swimming in cold water. The dangers to cold-sensitive individuals caused by swimming has been described in an editorial (Cold Allergy and Drowning, *THE JOURNAL*, Nov. 18, 1933, p. 1644). Shock symptoms such as these can be relieved with epinephrine. Local symptoms can be prevented by rubbing the hands briskly together, as mentioned. This serves to dilate the skin vessels and prevents abnormal cooling of the surface tissues. A slower reaction of this sort can cause what is known as chilblains. A certain degree of tolerance can be obtained for cases of this sort by ice rubs given by a person who understands this work.

Removal to a warmer climate and a change in occupation may be helpful.

ASTRINGENT SENSATION IN MOUTH

To the Editor—A woman aged 62, unmarried, of keen intellect and a high degree of culture (university professor) was exceedingly well and vigorous until sixteen years ago when she undoubtedly contracted amebiasis while on a visit to Mexico. Since that time she has had vigorous and prolonged treatment and is free from that infestation as I am convinced by microscopic sigmoidoscopic and therapeutic tests. Although there has persisted an intermittent looseness of the bowels. The patient complains bitterly of an astringent sensation of the mouth which has been very persistent since February of last year. She describes this as if she had eaten persimmons. It sometimes sets in suddenly after eating and in a very aggravated way. There is no apparent relation to foodstuffs except that she cannot tolerate milk. There is a noticeable accumulation of tartar and the teeth require frequent cleaning. Correction of dental defects has had no effect in relief. Sometimes there is a noticeable dryness of the mouth. During this period of eleven months there has been a noticeable increased nervous exhaustion, loss of appetite and loss of weight (15 pounds or 7 Kg.). Stimulation with insulin, ultraviolet radiation, halibut liver oil and thyroid extract by turn have been of no avail. It is to be remarked that thyroid extract in a dosage varying from 1/2 to 1 grain (0.03 to 0.065 Gm.) daily over a prolonged period has not increased the pulse rate of approximately 64. A stasis in the ileum twice demonstrated by roentgen examination could possibly be attributed to adhesions following appendectomy several years ago but there is no pain or tenderness. I am particularly concerned about the explanation of this very troublesome sensation of the mouth and inquiry is directed to that.

CARY A. POINDEYTER, M.D., Crystal City, Texas.

ANSWER—The clinical picture presented in this case suggests several possibilities in diagnosis and the further suggestion that treatment should be the usual treatment for the diagnosis finally arrived at. Except indirectly the former amebic infection would have no relation to the present condition. The residual damage from the amebic infection in the large intestine might be a factor as noted below. There must be considered (1) the possibility of food allergy, which should be worked out by the use of elimination diets. (2) the possi-

bility of xerostomia in a modified form, (3) the possibility of the entire condition being due or partly due to a pure neurosis, and (4) a condition occasionally seen clinically in which there is a more or less indefinite relation to disturbances of physiologic function in the large intestine. Attention to avoidance of any type of irritation of the large intestine, possibly with the attempt to change the bacterial flora, often gives improvement. This suggestion deserves especial attention in this case because of the ileac stasis and probable adhesions.

SYPHILIS

To the Editor—A man aged 26 with a chancre (positive dark field) and four plus Wassermann reaction was given twelve injections of neoarsphenamine. He weighs 150 pounds (68 Kg.) and his physical examination other than the chancre and inguinal adenopathy is negative. He was given 0.3 Gm. of neoarsphenamine two days later 0.45 Gm. two days later 0.6 Gm. and then 0.6 Gm. every seven days until a total of twelve injections had been given. The chancre started to heal at once and was completely healed after the fourth injection. Following the last injection he developed itching of the feet but no rash and a sense of heaviness in his legs especially after moderate exercise. The Wassermann reaction was still four plus. He was immediately started on mercury rubs six times a week. To date he has had eighteen rubs. The itching has somewhat diminished but the sense of weakness of the legs persists. Is this due to the injection or treatment? Careful examinations of the urine show no signs of kidney irritation. It is my plan to give between forty and sixty rubs and then return to neoarsphenamine or bismuth arsphenamine sulphurate. Is this treatment to date in accord with the latest conception of therapy? Is there any way of speeding up the treatment? The patient read somewhere that the use of mercury increases the incidence of tabes dorsalis and is reluctant to take mercury on this account. Is there any foundation to this belief? If so what would you suggest I use in place of mercury? Please omit name.

M.D., New York.

ANSWER—Itching of the feet is one of the danger signals occurring in the course of arsphenamine treatment and may be the forerunner of an impending arsphenamine dermatitis. A sense of heaviness or weakness in the legs may indicate nothing more than a mild degree of intolerance to arsphenamine. On the other hand, it may be an early symptom of an arsenical neuritis. If associated with a high cell count and a positive Wassermann reaction in the spinal fluid it might be interpreted as evidence of an early syphilitic cerebrospinal involvement or a neurorecurrence. The treatment of early syphilis with a combined therapy consisting of alternating courses of one of the arsphenamines with a heavy metal is in accord with the latest conception of therapy. Many syphilologists prefer bismuth to mercury and a course of eight or ten intramuscular injections of bismuth salicylate once weekly is frequently given. However there are many clinicians who still use mercurialunctions. There is no way of speeding up the treatment unless one wishes to use the method advocated by Schamberg of giving neoarsphenamines intravenously in doses up to 0.3 or 0.45 Gm. and a bismuth compound in doses of 0.2 Gm. intramuscularly on the same day. There is no foundation for the belief that mercury increases the incidence of tabes dorsalis. From three to five in every hundred syphilitic patients get the disease. Tabes may have been more frequent before the arsphenamine era when mercury and the iodides were used exclusively in the treatment of syphilis. Comparative statistics are difficult to obtain.

INDUSTRIAL HAZARD OF SPOT WELDING

To the Editor—I have under my care a man aged 23 who presents all the signs and symptoms of chronic arsenic (arsine gas) poisoning—pallor, nausea and vomiting, headaches and anemia—and gives a history of working at spot welding until he became too ill to work. The urine is heavily loaded with albumin. White blood cells number 10,000, red blood cells 2,500,000. Examination of the urine is negative for tubercle bacilli. The blood Wassermann reaction is negative. He also has a systolic murmur. The blood pressure is 160 systolic, 100 diastolic. Treatment has consisted of heavy doses of nephritin tablets and the intravenous use of sodium thiosulphate (10 cc.) weekly of which he has had three. About twice a week he develops headaches that are so severe that he requires hypodermic medication. None of the other sedatives that I have tried seem to help. I have alternated pantopon, morphine and codeine (in heavy doses) but would like to find something else to use or do to relieve them if possible. He has nausea and vomiting spells with the headaches. Is there any other management necessary or that you could suggest (other than diet) to aid him? Please omit name.

M.D., Ohio.

ANSWER—Spot welding with electrical apparatus is an unlikely source of arsenic poisoning unless there are special qualities about the metals employed or unless the welding is done with acetylene torch methods rather than electric currents. Acetylene gas occasionally contains arsenic as an impurity that originated in the materials from which the acetylene was produced. It would seem to be necessary that real exposure to arsenic at work or other places be established before a diag-

nosis of arsenic poisoning can be made. It is suggested that the hair obtained from a hair cutting of the head be analyzed for its content of arsenic. Something may be gained by an analysis of the urine for its quantity of arsenic content. Both the hair and the urine may normally contain arsenic, for which reason significance is to be attached only to amounts above the normal limits. Although the manifestations listed in the query are compatible with the diagnosis of arsenic poisoning, it appears that certain other striking features should be present such as inflammation of the upper respiratory tract, difficulty in breathing, neuritis, skin disorders and paresthesia. Instead of specifying precise medicaments, emphasis in this reply is placed on a more thorough quest as to arsenic exposure and for other etiologic factors that possibly may be the cause of the condition.

USE OF MORPHINE AND ATROPINE

To the Editor—May I ask the physiologic basis for the use of morphine and atropine in combined dosage? Apart from their being physiologic antidotes is there any reason why atropine should be combined with morphine when one is seeking the effects of morphine in pneumonia or other acute phenomena? Where can I find authoritative opinion or work bearing on the combined use of these two drugs? Certain textbooks in pharmacology such as Cushny state that morphine is a respiratory depressant. Does he refer to therapeutic doses? Is this depressant effect a contraindication to its therapeutic use in pneumonia and is it modified by the combined use with atropine? Authorities seem to differ regarding the therapeutic use of morphine in lobar pneumonia. Thannhauser of Germany for example states that morphine should be used only with venesection in pulmonary edema—in small doses—and holds that otherwise it is contraindicated. I have used morphine when indicated in pneumonia for many years with very satisfactory results. I can find little or no comment advising its use in textbooks or the literature and want to know what the best informed clinical opinion is in its bearing on this subject. In the consolidation of pneumonia during the hepatized stage when resolution and absorption are to be desired to what extent is the use of atropine indicated or contraindicated? Kindly omit name. MD New York

ANSWER—Morphine depresses respiratory functions especially the cough reflex, in all doses. Doses as low as 2 mg of morphine sulphate have a quieting effect, and 6 mg has a decided effect. This is explained by a direct effect on the respiratory center.

Small doses of morphine salts that quiet respiration would not be contraindicated in pneumonia and might be of benefit especially if there is an embarrassing cough which always adds a great strain on the heart. If given mainly for the cough, codeine may be preferable since its main effect is to lessen coughing usually without the constipation, itching or drowsiness that occur with the use of morphine.

When to use morphine or its derivatives in pneumonia is a debatable question. One finds that equally eminent physicians have different opinions. The following statement by Cohen and Githens (*Pharmacotherapeutics* New York D Appleton & Co, 1928 p 1693) is as conservative and as authoritative as the conditions permit. At one time morphine was held to have a restraining or even jugulating effect in lobar pneumonia if injected at or shortly after, the time of chill and many physicians still employ it from time to time during the course of the malady to assuage pain, check cough or induce sleep. The better plan however is to avoid its routine use at any stage in the evolution of the pneumonias. If the sedative influence of opium should seem imperative to afford needed rest in an individual instance codeine by mouth in a sufficient dose is commonly to be preferred and injection of morphine to be restricted to cases in which nought else will avail. Bastedo (*Materia Medica and Therapeutics* 1932 p 442) says that morphine in pneumonia has frequently precipitated edema of the lungs.

Since morphine is used not as a cure but to relieve pain and to give rest, there is no necessity for the use of atropine. Austrian (in *Tice's Practice of Medicine* 1925) says that atropine is valuable in the treatment of pulmonary edema.

Many physicians of large experience give morphine as soon as the patient is restless both to protect the heart and to improve respiration. The quieting effect rests the heart and while respiration is slowed they believe that the slower deeper respirations give better ventilation than the quicker and shallower ones. When restlessness, pain and cough endanger cardiac reserve Austrian advises from one-fourth to one-half grain (0.016 to 0.032 Gm) of ethylmorphine hydrochloride with each dose of digitalis enough to keep the patient digitalized. In any case when simple sedative measures fail to give rest opium and its derivatives powder of ipecac and opium from 0.3 to 0.65 Gm or codeine from 0.016 to 0.03 Gm is of great value not only in relieving pain but in promoting relaxation and sleep (Austrian).

Morphine and atropine are synergistic in producing narcosis. The synergism is greater with scopolamine than with atropine. Scopolamine is closely related to atropine but is less exciting and has a greater tendency to produce drowsiness. The combination of scopolamine with morphine has had considerable vogue in the production of twilight sleep. Some of the unpleasant effects of morphine are said to be minimized by atropine. The two are combined in the proportions of from 0.4 to 0.6 mg of atropine sulphate with from 8 to 16 mg of morphine sulphate. Each drug apparently exerts its own action, as given in any textbook of pharmacology.

To give atropine as an antidote for morphine, so far as man is concerned, would seem absurd. The experimental work on animals is contradictory, varying with the animal used and with the dose. Antidotal effects are obtained only with small doses, which need no antidote. The idea that morphine and atropine are antidotal in man probably arises from the contradictory animal experiments and from the custom of giving atropine with morphine preparatory to surgical anesthesia. It is given in such cases not as an antidote but to lessen mucous secretion during the anesthetic. At the same time, by paralyzing the vagus endings, the likelihood of arrest of the heart by reflex shock is decreased. Atropine is to some extent a respiratory stimulant but this is weak and would have little effect on the depression caused by morphine. In fact it would add to the depression. Authoritative opinion on the effect of the two drugs on respiration is given by Cushny in *Heffter's Handbuch der experimentellen Pathologie* 1924 page 605 and by Solimann (*Pharmacology* 1932 p 382).

We know of no indication for the use of atropine in any stage of pneumonia. However if conditions arise indicating its use we know no reason why it should be withheld. It should be remembered however that it causes dryness of the mouth and throat, thirst, difficulty of swallowing, dryness of the skin, rapid heart and often nausea, headache and giddiness, thus aggravating the discomfort already present. Since many physicians give digitalis in pneumonia atropine by paralyzing the vagus endings would tend to antagonize the effect of the digitalis. The two should not be given jointly.

In cases in which renal or gallbladder colic develops, atropine would be a distinct addition to morphine therapy. In such cases it acts by paralyzing the parasympathetic nerve endings to smooth muscle thus lessening the painful spasm.

CASTRATION VASECTOMY AND PROSTATIC HYPERTROPHY

To the Editor—I should like to have your opinion on the following points. An old method of treating prostatic hypertrophy was castration. Of course this never met with the favor of the patient although the results were often good. Now before prostatic work a vasectomy is done to forestall an epididymitis. How much does a simple vasectomy influence the prostatic condition? Should all the vessels both arterial and venous of the cord plexus be cut? Why would this not be equivalent to an orchidectomy? What effect would this have on the testicle? Would gangrene ensue or would it be a simple atrophy? What is our friend Brinkley doing? He is doing something of this sort. I did this operation once on a senile patient unknown to him to calm a violent sexual mania. The operation was entirely successful. How safe is this operation?

F T BRENNER MD Quincy Ill

ANSWER—The older method of treating prostatic hypertrophy by castration was abandoned not alone because it did not meet with favor by the patient but because it failed to give relief of the obstruction in too many cases to warrant so mutilating a procedure.

If a method of treatment that is intended to shrink the entire gland could be employed its exposure to high voltage roentgen or radium irradiation should be successful, not to mention suprapubic drainage of the bladder which is sometimes followed by the most marked diminution in the total size of the gland. Unfortunately, it is not the diffuse hypertrophy of the gland that causes the obstruction but only that small part of it which impinges on the urethra.

At times this portion is comparatively small, consisting of but 2 or 3 Gm of tissue but if properly located may cause complete retention while in another case a huge diffuse enlargement if it does not encroach on the urethra will result in little if any urinary obstruction.

Any rational therapy therefore must be directed against the removal of the portion of the gland causing the obstruction instead of against the entire gland. For this reason the new methods of transurethral resection of the obstructing tissue are meeting with much success.

A simple vasectomy in no way influences the portions of the prostate that are causing the urinary obstruction and hence is useless as a therapeutic measure for its relief. When it is performed the arterial and venous vessels should not be cut

but simply the vas deferentia. Cutting of the vessels of the spermatic cord will usually lead to atrophy rather than gangrene of the testis. Such atrophy should be avoided, as few men, even of advanced years, care to be emasculated even indirectly. When employed for the treatment of a sexual mania, it may be justified. Vasectomy under sterile precautions is without risk and by many is considered an office procedure. Brinkley is said to employ it as a method of treatment for urinary obstruction the result of prostatic hypertrophy.

TREATMENT OF AMEBIASIS

To the Editor—Will you please tell me what you consider the most effective treatment to date for amebiasis? We frequently see it down here. I have used emetine hydrochloride by needle Anayodin. There is Lilly's preparation on the market also another new chemical. Please give me your opinion. What do you think of Plasmochin (Merck) and Atabrine (Winthrop Chemical Company)? I have always used the standard quinine treatment with success but there are a great many objections to it.

B O LeBLANC MD St Gabriel La

ANSWER—According to a group of investigators in California and another group in India, both widely experienced in the treatment of amebiasis, Carbarsone (Lilly) is one of the most efficient remedies in this disease so far tested. However, many cases prove refractory to this as well as to the other remedies. Vioform-Ciba is claimed by the California group also to be high in efficiency, but this drug is said to be less effective than Carbarsone. Alternating courses of Vioform and Carbarsone are claimed to have given good results.

The present consensus is that emetine should be used only to control the symptoms of severe acute amebic dysentery and in liver abscess (or amebic abscess of other organs). Even small therapeutic doses of emetine have occasionally caused severe damage to the heart and other organs. Acetarsone-N N R is reported to be more toxic and less effective than Carbarsone. Patients must be watched carefully for signs of arsenic toxicity when using either of these compounds. Good results have been obtained with Chimofof-N N R ("Yatren" "Anayodin") in sufficient dosage, this drug has been said to be less effective than Vioform, a closely related compound. Vioform has the advantage over Chimofof that it does not cause diarrhea. However, clinical experience with Vioform has not yet been sufficiently extensive to determine its actual relative merit as an amebicide. Fairly good results have been reported by Indian workers with kurchi alkaloids, but Leake and his collaborators were unable to confirm this work. THE JOURNAL knows of no evidence for the usefulness of Plasmochin or Atabrine in amebiasis.

"Anayodin" is a proprietary name for a Chimofof-N N R, marketed by Ernst Bischoff Company, Inc. The Council on Pharmacy and Chemistry was obliged to declare Anayodin inadmissible for New and Nonofficial Remedies because it is an unoriginal preparation marketed under a noninformative name without an adequate statement of composition, because no evidence is available to show that its identity and uniformity are adequately controlled, and because it is marketed with therapeutic claims that are unwarranted. Two brands of Chimofof stand accepted for inclusion in New and Nonofficial Remedies, namely, that of G D Searle & Co and that of the Winthrop Chemical Company. These have been examined in the A M A Chemical Laboratory and found acceptable. The Winthrop brand was formerly known as Yatren but the firm has agreed to discontinue the use of this name.

Whichever drug or combination of drugs is used it must be employed in sufficient dosage over a sufficient length of time with due regard to necessary rest periods to avoid toxic manifestations. The result should always be checked by careful and repeated examinations of the stool for *Endamoeba histolytica*.

Chimofof, Vioform, Acetarsone and Carbarsone stand accepted for New and Nonofficial Remedies.

NO NERVE CELL DEVELOPMENT AFTER BIRTH

To the Editor—Is there any evidence to show that additional nerve cells are produced after birth?

L A CROWELL JR MD Lincoln N C

ANSWER—In the white rat, Allen (*J Comp Neurol* 22 547, 1912) found that mitosis continued after birth in the spinal cord for twelve days and in the cerebrum for twenty-five days. But the white rat is born in an immature state and these observations cannot be taken as evidence that the same would hold true for the child. We have been unable to find any record of similar observations on human material but judging

from the more mature state of the child at birth it would seem probable that in the human central nervous system mitosis ceases about the time of birth.

COMPRESSION FRACTURE OF LUMBAR VERTEBRAE

To the Editor—Please outline for me the best recognized and used methods of treating compression fracture of the lumbar vertebrae in an adult. There are many methods outlined in textbooks and journals and I am at a loss to know which method is best to follow.

P T KILMAN MD, Malakoff Texas

ANSWER—Much progress has been made during the last decade in the treatment of fractures of the spine. This is due chiefly to the contributions of J O Wallace (*J Bone & Joint Surg* 5 28 [Jan] 1923), A G Davis (*J Bone & Joint Surg* 11 133 [Jan] 1929, *Am J Surg* 15 325 [Feb] 1932), W A Rogers (*Surg, Gynec & Obst* 50 101 [Jan] 1930), R Watson Jones (*Brit M J* 1 300 [Feb 21] 1931), Dunlop and Parker (*THE JOURNAL*, Jan 11, 1930, p 89, *Radiology* 17 228 [Aug] 1931) and Bohler.

A comprehensive, simple outline to follow, is to transport the patient with his face downward, transfer him to a Rogers hyperextension frame, administer an anesthetic, accomplish gradual hyperextension, apply a plaster-of-paris cast, and if necessary perform a fusion operation through a window in the cast.

No one method can be used for all types of spinal fractures. Each case demands individual treatment.

Davis stated that the procedure of reduction and the making of his plaster shell requires an hour and a half. There was an average period of seven weeks of shell treatment, followed by an average of six more weeks of convalescent ambulatory treatment with a hyperextended Taylor brace or jacket.

Complete reduction of fresh crush fractures is possible when adequate hyperextension and fixation have been accomplished. Several adequate methods of hyperextension are now available. R Watson Jones advocates a method of reducing crush fractures of the spine that appears safe and simple.

Dunlop and Parker described a method of forcible extension during traction producing decompression and reduction. The patient is given a general anesthetic, strong traction and countertraction arc obtained by having two assistants pull downward on the ankles, while two others pull strongly upward on sheets crossed beneath the shoulders and over the chest. A sheet is folded to a width of 8 inches and is passed beneath the injured segments as the patient lies on his back. Then by means of this sheet the operator and his assistant toss the patient straight upward and catch his weight while he is still in hyperextension. Strong traction is maintained through this maneuver. After decompression has been accomplished the reduction is maintained by placing the patient in marked hyperextension on a Goldthwait frame while he is still completely relaxed. A cast is then applied.

In his most recent contribution, R Watson Jones reports the results of treatment of eighty cases of crush fractures of the spine by his own method, which requires no special apparatus, no skilled assistants, no manipulation of the spine and no anesthetic. The treatment is ambulatory throughout. The only contraindication to his hyperextension treatment is the very rare comminuted hyperextension fracture of the vertebral body.

No mention was made in the query of spinal cord symptoms.

GLANDULAR CONTROL OF SIZE OF BREAST

To the Editor—I have a patient a Jewess aged 17 who began menstruating at 13 years of age. She is 5 feet 1 inch (155 cm) tall weighs 117 pounds (53 kg) and is well proportioned. The menstrual periods are regular and apparently normal. The basal metabolism is plus 5. A roentgenogram of the pituitary shows a very small sella turcica the anterior and posterior clinoid processes closely approximating each other. She has never been ill except when the tonsils were removed. The trouble is bilateral hyperplasia of the breasts. The breasts began to enlarge at 14 years of age and enlarged rapidly for about one year. Since then the enlargement has been slow. Each breast will easily fill the hat of a man. There is no glandular enlargement in the axilla or the neck. There is no evidence of circumscribed tumor in either, no pain nor tenderness no retraction of the nipple no adherence to the skin. Could this be due to the predominance of the sex stimulating hormone over the growth promoting hormone of the anterior pituitary? Is there any effective treatment other than amputation?

M D, Texas.

ANSWER—Excess production of the gonad and mammary stimulating hormone from the hypophysis will increase the size of the mammary glands even in the mammalian male, but the absence of indications of other disturbed anterior lobe functions and the absence of indications of disturbed ovarian functions seems to render this explanation improbable. There may be unusual sensitiveness of the mammary glands on a hereditary

basis, so that the normal hypophyseal and ovarian factors produce excess response in this particular patient

As to experimental therapy, the following might be tried

1 Without reference to the cause of the unusual breast enlargement, reduction of the breast size might be attempted by continued pressure (taping or strapping) on the basis of pressure atrophy. Such measures should be as continuous as possible and sufficient to reduce circulation markedly through the breasts

2 If a thorough trial of the pressure atrophy principle should prove unsatisfactory, high voltage roentgen therapy of the hypophyseal region might be instituted experimentally with great care, with the possibility that an overactive group of gland cells may be more sensitive to the x-rays than the normally acting gland cells. It is obviously important for so young a patient that injury to the parts of the normally functioning hypophysis be avoided

POLYURIA IN TACHYCARDIA

To the Editor—A woman aged 55 has had recurrent attacks of paroxysmal tachycardia at about weekly intervals. The attacks generally wake her from sound sleep. About ten minutes after the onset she passes tremendous quantities of very pale urine (as much as 3 quarts). After about an hour the heart slows down and the urination ceases abruptly. Following these attacks she feels excessively thirsty and drinks a comparable amount of water. This thirst persists for a day or more. I have been unable to find any explanation for this sudden transient polyuria. Have you any information as to the mechanism of this strange symptom? Please omit name. MD New York

ANSWER—Polyuria during an attack of paroxysmal tachycardia is apparently of infrequent occurrence. Lambert quotes Hart's description of a case in which both diarrhea and polyuria were present during the paroxysm. No explanation is offered. Price comments on the fact that polyuria not infrequently follows a prolonged attack in which there has been impairment of the circulation with congestion, and, on restoration of normal cardiac function diuresis follows.

Lewis says "The patient's symptoms are much influenced by the reaction of the nervous system. Nervous subjects especially women awaken undue anxiety." That apprehension exists with the attack in spite of reassurance and repetition of a favorable outcome is a common observation. That there is a definite neurogenic factor in renal excretion is generally accepted (MacLeod) although the burden of proof has been that the kidneys do not possess secretory nerves. It is frequently noted, however, that under stress of excitement or anxiety diuresis is initiated.

This mechanism then must be a vasomotor effect resulting in an increase of blood flow through the kidney with or without a general increase of blood pressure.

When the heart is anatomically unimpaired, paroxysmal tachycardia, unless extremely prolonged does not alter its efficiency, and circulation is well maintained (Lewis). Reflex phenomena affecting the sympathetic nervous system such as sweating and dilatation of the superficial vessels of the skin commonly occur. It is possible that similar reflex vasodilatation might occur in the kidneys.

While the general blood pressure is usually lowered during an attack of paroxysmal tachycardia, exceptional cases may occur presenting an increased blood pressure.

CODEINE PHOSPHATE IN SOLUTIONS—COLORING OILY SOLUTIONS

To the Editor—1 In the following prescription is there any way to mix the ingredients to avoid precipitation of the codeine present?

℞ Ammonium chloride	Per Ounce
Codein phosphate	8 grains
Chloroform	2 grains
Syrup of prunus virginiana	2 minims
	ad 1 ounce

2 What will color oily solutions red and yellow readily? Please omit name and address. MD Conn

ANSWER—The syrup of wild cherry is responsible for the precipitation which is obviously due to the tannic acid it contains and the formation of a codeine tannate. This can be avoided by using some other syrupy vehicle, such as the syrup of raspberry. Even with such a syrup a temporary precipitation—salting out—of the alkaloid occurs if an attempt is made to dissolve each of the solid ingredients in the smallest amount of water required for solution and then mix these. Although this precipitate dissolves on standing after the addition of the syrup it is probably better to dissolve each of the solids in half of the syrup and then mix the two.

2 For red coloring of oils, alkanet is used, for yellow one might use the ordinary "butter yellow," which is dimethyl-amido azo-benzene

DINITROPHENOL CONTRAINDICATED IN DIABETES

To the Editor—Several diabetic patients are requesting me to prescribe dinitrophenol for reducing. I have not seen an article on the use of this drug when it was advised or not advised to be used in such cases. Have you any opinion on the subject?

S L WEISBROD MD Milford Mich

ANSWER—In the light of the fatal poisoning that has occurred with dinitrophenol, there is little to be said in favor of using the drug for reducing anybody. There are even stronger reasons to oppose the use of dinitrophenol when the patient has diabetes. The tolerance in diabetes is depressed by measures of all kinds that elevate the basal metabolic rate, and this is the action of dinitrophenol. Furthermore, the liver is less able to withstand toxic substances when its glycogen reserves are diminished, as they always are in diabetic acidosis. For these reasons dinitrophenol is distinctly contraindicated in diabetes.

PARAFFINIZATION OF LENIN

To the Editor—I should like to know whether the process whereby Lenin of the Soviet government has been embalmed has been revealed. What probabilities are there if any to your knowledge? Please omit name. MD New York

ANSWER—No record has been found of the process of embalming the body of Lenin. There are many indications, however, that the body was embalmed by infiltration, most likely with paraffin or some similar preparation. Successful paraffinization of large anatomic specimens, including the adult human bust has been accomplished. See Ara, Pedro. The Process of Embalming, *J Technical Methods and Bull of the International Association of Medical Museums* 1934, No 13, page 36.

AMEBIASIS WITH CONSTIPATION

To the Editor—I have a patient who says that amebas have been found in his stools and that he has never had diarrhea. On the contrary he is constipated. Please advise whether this is possible. Is any special dietary restriction necessary in the treatment of such a condition? If so please outline. Please omit name. MD Kentucky

ANSWER—The history given is entirely within the realm of clinical possibilities. If the amebas are positively identified as *Endamoeba histolytica*, suitable treatment with emetine, vioform, chiniofon or carbarsone, or other amebicidal drugs should be instituted. The diet during the course of treatment should be bland.

PROPER CARE OF ORBIT WITH GLASS EYE

To the Editor—I have a patient troubled with a mucopurulent secretion around his glass eye. Will you please send me a prescription for a solution that will inhibit or stop this? He has used the glass eye for several years. Please omit name. MD California

ANSWER—The patient may use saturated boric acid solutions to irrigate the conjunctiva, after removing the prosthesis, two or three times a day, drying the conjunctival sac with a cotton applicator and instilling powdered boric crystals afterward. In addition, 0.5 to 0.75 per cent zinc acetate made up in saturated boric solution should be used four times a day. It is well to have the patient discontinue using the prosthesis for two or three days at a time after which one gets better results with this treatment.

LIVER GROWN

To the Editor—As you probably recall there have been several references in THE JOURNAL in the past few months to the condition called "liver grown." In reading Haggard's *Devils, Drugs and Doctors* page 186 I note a list of causes of death for the week Aug 15 to 22 1665. This seems to be a report of the city of London, England. "Liver grown" appears as the cause of one death column two down five. It is interesting to note the name being used almost three hundred years ago even if we do not know the disease.

RONERICK L HUNTRESS MD South Portland Me

ARSPHENAMINE REACTIONS

To the Editor—Referring to your discussion on Reactions After Arphenamine in *Queries and Minor Notes* in THE JOURNAL May 12 page 1633 may I suggest also that the needles be boiled separate from the syringes and that there be no metal on the syringes. I have found better results from this technique.

Book Notices

Diet and Dental Health By Milton T Hanke Cloth Price \$1 after February 1 1934 \$4 Pp 236 with illustrations Chicago University of Chicago Press 1933

The author states that the primary object of the book is to present detailed information concerning studies on dental problems carried out in the laboratories of the Otho S A Sprague Memorial Institute at the University of Chicago by the Chicago Dental Research Club, other collaborators and himself during four years. No attempt is made to give detailed descriptions of studies and theories of other investigators. The subject is approached from the view that disease is a disturbance in metabolism, a reaction of body tissues to and against some unfavorable circumstance, and that dental diseases do not differ fundamentally from other diseases in this respect. Chapters II and III discuss dental structures and the simpler dental diseases. Chapters IV and V deal with the histopathology of scurvy in the guinea-pig. The remainder of the book is devoted to experiences with dental diseases in people. Chapter VI summarizes investigations of the relation of dietary deficiencies to gingival irritation, pyorrhea and dental caries from observations on 191 patients of members of the Chicago Dental Research Club. Chapter VII notes benefits derived from ingestion of an adequate diet. It is postulated that the American diet is deficient in vitamin C and that this may be a factor in dental diseases.

Part II outlines observations on 440 children at "Mooseheart," the City of Childhood of the Loyal Order of Moose at Mooseheart, Ill. This part of the work was financed by the California Fruit Growers Exchange. Chapter IX outlines the plan of study. A group of 341 children were under observation for three and one-half years, which time was divided into three periods: a one year control period in which the children received the standard Mooseheart diet, a one year test period in which one pint of orange juice and the juice of one lemon were given each individual daily in addition to the standard diet, and a recheck period of one and one-half years in which 3 ounces of orange juice was served daily. A control group of ninety-nine children receiving the standard diet but no citrus fruit juice was introduced during the test period to serve as an additional check. The experimental procedures followed during the control period and the results obtained are described. Chapter X gives the observations of the test period, including those on the control group. Chapter XI outlines the observations of the recheck period. The bibliography provides some important published reports on the subject. The appendix presents tabulated data from the observations on the children. A number of plates illustrate the dental and oral conditions discussed.

The general conclusions of the book follow:

1. The average American diet is adequate in calories but appears to be deficient in certain substances requisite to dental health which may be the ultimate cause of much gingivitis pyorrhea and dental caries.

2 Gingivitis and dental caries can occur in the majority of a large group of children receiving a quart of milk, 1½ ounces of butter a pound of vegetables half a pound of fruit and nearly one egg a day. These foods do not therefore contain substances specifically antagonistic to gingivitis or dental caries.

3 The addition of a pint of orange juice and the juice of one lemon to a diet that is nearly adequate in all other respects supplies something that leads to a disappearance of most of the gingivitis and an arrest of about 50 per cent of the dental caries.

4 Dental caries again becomes rampant and gingivitis redevelops in most of the cases when the citrus fruit intake is reduced to 3 ounces a day for one year. This quantity is not enough.

5 Children display a definite tendency toward the development of carious lesions which is nil or low in some cases and high in others. The administration of an adequate amount of citrus fruit juice to a diet that is nearly adequate in other respects reduces the intensity of the caries process but does not completely remove the effects of the inherent tendency in all cases.

6 Orange and lemon juice contain something that acts as a growth stimulus to children.

It is difficult to evaluate this book in a thoroughly objective manner. To the untutored layman, its easy style and satisfying comments bring ready conviction. This is particularly true as its contributions seem to be vigorously fortified by the use of the names of distinguished research laboratories and academic institutions. On the other hand a critical reader will discover not only much that is evasive and frankly debatable but also much that can scarcely claim to be more than possible, if indeed it is within the realm of scientific probability.

The main theses of the book are included in the somewhat surprising statements of paragraphs 2 and 3 of the conclusions quoted.

It is understood that the term gingivitis is loosely used by many writers. Some degree of superficial gingivitis will be detectable in almost any mouth and is readily relieved or managed by routine dental hygienic measures. This is a problem quite different from that presented by true scorbutic gingivitis. There is an implication throughout the book that despite the absence of diagnosed scurvy in the children studied they are subject to a sort of latent or subacute scurvy which makes itself evident in the gingivitis conditions. This is at best an unproved assumption which the author attempts to support by analogy with guinea-pig and monkey scurvy. There is no real scientific evidence anywhere in the book to show that the children examined exhibited comparable scorbutic lesions or that they had any gingivitis of the type associated with human scurvy.

A few surprising features of the book may be briefly referred to. A comparison of plates VI and VII shows the feature D to be reversed in the form of the "curve" in one picture as compared with the other. What can this signify? Regarding plate XIII, all children have such plaques. What of it? The conception of dental diseases as evidenced by Hanke's descriptions is utterly inadequate. Some children are admittedly far more susceptible to caries than are others. The author has not been able to control this. Age is an important factor in the incidence of caries. It decreases as children grow older. This fact the author has ignored. The references to authorities on dental pathology largely overlook some of the best, such as Gottlieb, Orban and Chase.

The author's own uncertainties are exhibited in statements such as the following:

Either the living processes in the dentine of the immature permanent teeth remove the decalcifying agents as rapidly as they seep into the enamel or some change occurs in the oral cavity so that decalcifying agents are either not produced or are rapidly rendered ineffective. It is possible to alter some people's susceptibility to dental caries and this can apparently be accomplished in a number of ways.

The case studies such as the one on page 60 are very inadequate if they are to serve as real evidence.

Judging by the prefatory statement of the members of the Chicago Dental Research Club at the outset, there was conviction as to the outcome even before the tests were made. Apparently all the examinations were made by only two dentists. They could not fail to know when the children were on the test periods. It is difficult to remain objective under such conditions.

The key to the results with caries may be found in table XLII. It is quite as likely that the results recorded if actually dependable, are due to some change within the mouth cavity.

It is an interesting circumstance that all the recent students of caries in children, for instance Bunting, Boyd and Drann

and Agnew, also secured an arrest of caries after they began to work with their patients, although they used quite unlike procedures!

At the opening of chapter II, the author writes:

Dental diseases are not fundamentally different from other diseases but they are comparatively easy to diagnose because the affected tissues are open to observation. Conditions in the mouth are certainly no more complicated than elsewhere in the body; they may indeed be simpler. We need to deal with only a few structures. Treatments local and otherwise may be given and the response if any observed by direct inspection. Inasmuch as systemic disturbances frequently produce changes in the oral tissues it is possible that conditions easily observable in the mouth may be an index of systemic disturbances of which we are only vaguely or not at all conscious. The oral cavity constitutes an excellent region for study.

Although the last sentence is fundamentally correct, the rest of the paragraph is contrary to the opinion of the best students of the subject.

An illustration of the author's dogmatism follows:

Fully formed enamel consists of hexagonal prisms or rods held together by a very narrow band of cementing material. The body of the prisms appears to consist entirely of inorganic salts. The small amount of organic matter to be found in enamel appears to be contained exclusively in a narrow band that makes the dividing line between the prisms.

This is by no means a universally accepted doctrine.

The limitations of Hanke's argument are indicated in the following statement:

The conclusion can probably be drawn that prescurvy in man can lead to changes in the pulp tissue and dentine of human teeth similar to those determined for the guinea pig. The nature of the repair process will also probably be similar. Administration of vitamin C to mildly scorbutic animals leads to a complete repair of the dentine. Diets rich in vitamin C are conducive to an arrest of dental caries in man and the arrest of caries may be due to an increased vitality of the dentine. Howe has shown that monkeys that have been partially deprived of vitamin C develop dental diseases identical with those encountered in man. Frank scurvy in man is grossly similar if not identical to frank scurvy in the guinea pig. The facts presented in this chapter can with a few intelligent reservations probably be applied to man.

This is at best a theory of probabilities. As for the work of Howe, it is believed by many that his monkeys suffered from multiple dietary deficiencies, and nothing is contributed thereby to the caries problem.

The principal criticism of the dietary program is that there are no records for the intakes of individual children. The food supplies are reported in terms of the entire group. There is no assurance regarding the eating habits of the individual child. How can the use of the products in table V, page 79, be evaluated? Certainly this does not represent a daily intake, it represents purchases over a period of time. What assurance is there that 'all of these children were ingesting the same food and they were living under identical conditions. The food and the living conditions cannot, by themselves, then, be the determining factor'.

The author correctly states (p 103) that:

The changes observed during this test period may just as correctly be attributed to the increased adequacy of the diet as to a specific characteristic of the citrus fruit juice.

This is quite different from the impression that is promulgated throughout the book.

The author makes the debatable statements:

The inflammation can hardly therefore be said to have been due to the materia alba or plaque deposits. It is rather more logical to assume that the inflammation is initiated by an impairment in the circulation due in turn to a deficiency in the diet. The results obtained with five children in this group strengthens our belief that vitamin C is an important factor in maintaining the health of the gingivae (p 105).

The addition to the diet of one constituent in which this diet was deficient has produced a change such that about half of the children who had previously been afflicted with dental caries did not develop carious lesions during a one year period (p 109).

Mixtures of orange and lemon juice add several factors to the diet.

What is one to conclude from the statement (p 118):

These children were receiving the standard Mooseheart diet but they were not supposed to (and most of them did not) receive additional orange or lemon juice.

The author states (p 120) that:

The addition of a pint of orange juice and the juice of one lemon to the daily diet leads to an almost complete disappearance of the gingivitis, a 50 per cent reduction in the incidence of dental caries and a marked increase in the rate of growth.

These diets were probably inferior at the start!

On page 121, the author writes

It is immediately apparent that the only major fluctuation in this diet, during a three and one-half year period is in its citrus fruit content. This increases from 0.062 lb in the control period to more than 1.0 lb during the test period and then decreases to 0.28 lb during the recheck period. The amount of citrus fruit ingested during the recheck period is equal to approximately three ounces of orange juice a day which is the amount that is usually considered to be adequate.

To what extent did the citrus fruit juices supply added energy (280 calories a day?) and their vitamin B promote greater intake of other foods?

The author comments on page 137

Whether or not foods other than citrus fruit juices would be equally or more effective in overcoming the inherent tendency toward dental caries is a question that is not answered by our studies.

Apparently the possible variations in sugar, for instance, have not been considered in drawing conclusions. One cannot tell what the effect of 1 pint of orange juice a day was on the food habits of the children.

The theorizing of the author regarding the role of vitamin C in these studies is, like so much else, quite problematic and debatable. There is too much inference that vitamin C is the effective factor. Little recognition is given to other factors.

The book does not furnish cogent evidence for the thesis that orange and lemon juices are specifics for the cure or prevention of gingivitis and caries.

Chronic Nephritis and Lead Poisoning By L. J. Jarvis Nye M.B. Ch.M. Cloth Price 12/6 Pp 145 with illustrations Sydney Australia Angus & Robertson Ltd 1933

For many years there has been much more chronic nephritis among young people in Queensland than in any other area of Australia. The author develops the thesis that lead poisoning among infants and children is the cause of this increased incidence. To prove his contention he examined and here reviews considerable relevant statistical material concerning, for example, the relative incidence of chronic nephritis and of lead poisoning in the various Australian states, the remarkable prevalence of infantile lead poisoning in Queensland, the incidence of chronic nephritis as a sequel to plumbism, the criteria necessary for a diagnosis of plumbism, and other data. In discussing the diagnosis of lead poisoning, he states that occasionally in severe, typical cases, there is no lead in the urine. In particular, Nye studied, over a period of six years, 186 cases of chronic interstitial nephritis among persons less than 40 years of age. Evidence is presented that the sclerosing agent responsible for Queensland's excess of juvenile nephritis was not directly related to scarlet fever, respiratory infections, syphilis or other infectious diseases, or to climatic factors. A large number of the nephritic children studied by the author and by others had sometime previously been treated for lead poisoning. Lead was found in the urine of the majority of these nephritic children, most of whom were addicted to nail biting and finger sucking. If one of several children in a family escaped nephritis, that one was generally found not to be addicted to these habits. Data are given to indicate that the lead absorbed was not from the water supply, home reservoir tanks, sprayed vegetables, utensils or toys but from the lead carbonate available in house paint on veranda railings of Queensland's characteristic frame houses. The paint became readily desiccated as a result of the tropical climate. The author contends that the finger-sucking children introduce this powdered paint into their systems. The chemical and pathologic features of the resultant nephritis are described: chronic interstitial nephritis (arteriosclerotic contracted kidneys of the diffuse sclerotic type) associated with anemia, hypertension, retinal changes and azotemia. While Nye admits, of course, that lead poisoning is not the only cause of chronic interstitial nephritis, and that many victims of moderate lead poisoning probably escape significant renal injury, he concludes that in chronic nephritis among young adults lead is the first etiologic factor to be excluded and that every child suffering from lead poisoning is potentially a victim of chronic nephritis in later life. Recommendations concerning prevention by the use of an improved formula for paint are given. Although the author's researches suggest that the subject is a problem particularly of his own locality, the book should be of considerably more

than local interest, and it may stimulate significant inquiries in other places. If persons with nephritis individually or collectively can be shown by others to be suffering in an appreciable number of instances from related plumbism, the publisher's contentions may be fully justified that as a contribution to medical science this work is "the most important to come out of Queensland since Bancroft discovered the adult filarial worm fifty-seven years ago."

Practical Methods in Biochemistry By Frederick C. Koch Professor of Physiological Chemistry University of Chicago. Cloth Price \$2.25 Pp 282 with 17 illustrations Baltimore William Wood & Company 1934

This is a laboratory manual intended primarily for the use of medical students, for which purpose it appears to be admirably adapted. It is sufficiently complete and so organized that it will be found an excellent book of reference for those interested in the details of biochemical methods. The work is divided into three parts: the chemistry of cell constituents, which includes chapters on carbohydrates, lipins, proteins, nucleoproteins and nucleic acids, and hydrogen ion concentration; the chemistry of the digestive tract, containing sections on salivary, gastric and intestinal digestion and on the bile, the blood and urine, under which heading the author considers blood and hemoglobin, quantitative analysis of blood, quantitative analysis of urine, and chemical examination of urine for pathologic constituents. An unusually detailed appendix contains instructions for the use and care of apparatus and reagents and for the preparation of solutions. This volume is unusually well written, instructions are clear and meticulously accurate, explanatory notes of considerable assistance to students are liberally interspersed throughout the text, the scope of the subject matter is exceptionally broad. These and other features all contribute to making the work easily one of the most valuable textbooks in practical biochemistry now available.

Undersøgelser over de serologiske Blodtype Egenskaber M og N (Landsteiner & Levine) Af Jørgen Clausen (Mit deutscher Zusammenfassung) Paper Pp 104 Copenhagen Levin & Munksgaard 1934

This is a thesis for the doctor's degree. In 1927 Landsteiner and Levine described certain new receptors in human red blood cells which they designated M, N and P. The receptors M and N are well defined and hereditary factors which are present as M, N or M, N consequently can be used to differentiate blood for practical purposes. In his thesis Clausen discusses completely the technique of demonstrating receptors by immunization and purification of the immune serum by means of specific absorption, their heredity, their chief characteristics, their absence outside the red blood cells, their medicolegal significance, and the lack of any evidence that they are of any harm in blood transfusion. The thesis is in Danish, there is a German summary, which is not quite adequate because it tells too much what was done and too little of the actual results obtained.

Review of Legal Education in the United States and Canada for the Year 1933 By Alfred Z. Reed Staff Member in Charge of the Study of Legal Education Paper Pp 67 New York Carnegie Foundation for the Advancement of Teaching 1934

In this review Mr Alfred Z. Reed presents a discussion of the broad topic, "Learned Professions and Their Organization." He specifies three groups that are especially interested in finding their way through the educational labyrinth: the university authorities, the legislatures, foundations and individual benefactors, from whom financial support is derived, and the students who must choose from among the educational opportunities confronting them. "The solution," Mr Reed declares, cannot be delegated to practitioners' associations or coordinating associations. After paying his compliments to the American tendencies toward organization and specialization, the author describes three methods of state regulation of professions. In England, quite generally, specially privileged corporations have been created, livery companies, royal colleges, societies, inns, institutions and institutes, which exercise the function of admitting to practice. At the other extreme a state may provide a professional service directly through the agency of its own officials. Intermediate between these two is the system of issuing individual licenses under governmental authority. A

procedure widely prevalent in the United States. Included is a list of law schools in the United States and Canada segregated into two groups, those requiring full time attendance, of which there are eighty-three, and those which demand only a part of the student's time, numbering 107. Copies of this review and of other publications dealing with legal education may be had without charge at the office of the foundation 522 Fifth Avenue, New York.

La lutte internationale contre le cancer. Par le Docteur Jacques Banda, Directeur de l'Institut de Physiothérapie de Binritz. Avant-propos des Professeurs Ferdinand Blumenthal, A. H. Roffo, C. O. Jensen, C. C. Little, W. V. de Vries, Pietro Gallenga et V. Rubesca. Préfaces du Sénateur Justin Godart, ministre de la Santé Publique et du Professeur Gustave Roussy, directeur de l'Institut du Cancer de Paris. Paper. Price 145 francs. Pp. 947 with 46 illustrations. Paris: Norbert Maloine 1933.

In this volume the author has attempted to review cancer control activities in about fifty countries. The development of the cancer problem in France is given in chronological order and is of considerable historical interest. The author presents a variety of details, including the organization of cancer hospitals, the formation of local, national and international anti-cancer societies, the researches and publications of different authors, the personnel and equipment of cancer institutes and some of their published results. The sources of income and budgets are given and the names and addresses of officials of various cancer societies and organizations are listed. The author has attempted to accomplish a unique and difficult task. He has succeeded in evolving a publication that contains much useful information that is scattered in the literature. Apparently he has not had the opportunity to visit many of the institutions he describes so that the compilation lacks a critical point of view. The volume contains much interesting information and affords a useful guide to any one interested in the problem of cancer control as it is practiced in the various countries of the world. There is probably no other treatise that has attempted to present the same type of material from a similar point of view. The author is to be congratulated on his industry in gathering such an extensive mass of data from widely scattered sources. Those interested in these phases of the cancer problem will find the book a valuable source of information.

The Study of Anatomy Written for the Medical Student. By S. E. Whittall, M.A., M.D., B.Ch., Robert Reford, Professor of Anatomy, McGill University, Montreal. Second edition. Cloth. Price \$1.50. Pp. 93. Baltimore: William Wood & Company 1933.

This little book might have had another title, to wit 'Guiding Principles for the Study of Anatomy and the Mental Life of Medical Students'. The guides for the study of anatomy are in brief the following: 1. The student should know the body rather than the book. 2. Main structures are more important than details. 3. Anatomy must be absorbed slowly and repeatedly. For technique, the author advises (1) careful dissection with a sharp knife and (2) study of the dissection by drawing it, describing it and comparing it with cross sections. Among the suggestions for healthy mental life are to (1) make a lifelong friend of the first textbook of anatomy, (2) study some popular and foreign books on anatomy for collateral reading, (3) seek mental recreation in some side interest, (4) learn the value of humor and laughter as therapeutic agents, (5) have a bedside library such as Osler's ten books, and through it develop the mind of a scholar and a gentleman, and (6) remember that one third of your work will be entered on other books than yours, work as counselor and friend. The book is well written in a wise and kindly way. It will commend itself. The students who read it will be influenced through it to be happier and sounder doctors, wiser friends and better gentlemen.

Szpitały ogólne w Polsce i Polskie Towarzystwo Szpitalnicze. Les Hôpitaux généraux en Pologne. Association Polonaise des Hôpitaux. Paper. Pp. 83 with illustrations. Warsaw: Polish Medical Press Propaganda Office 1933.

This is the first number of a series to be published as follows: Contagious Diseases and Tuberculosis in 1935, Psychopathic Institutions in 1937, Maternity and Children's Hospitals in 1939, Clinical Hospitals in 1941. The treatise on General Hospitals for the ensuing ten years will be published in 1943.

General hospitals are operated chiefly by municipalities or counties. Those operated by the government are of recent date and few and they are managed by the health insurance office (a government institution). In 1932 Poland had one hospital bed to each 453 inhabitants and only 47 hospitals of 250 beds or over in the total number of 726 hospitals with 70,937 beds. The population of Poland according to the census of 1932 is 32,132,936. A questionnaire disclosed an urgent necessity of at least two beds per thousand inhabitants as well as a general desire of the removal of hospitals from the influence of health insurance and advisability of conducting a course for hospital directors.

The Management of Fractures, Dislocations and Sprains. By John Albert Key, B.S., M.D., Clinical Professor of Orthopedic Surgery, Washington University School of Medicine and H. Earle Conwell, M.D., F.A.C.S., Orthopedic Surgeon for the Tennessee Coal, Iron and Railroad Company, Birmingham, Alabama. Cloth. Price \$15. Pp. 1164 with 1165 illustrations. St. Louis: C. V. Mosby Company 1934.

Written by two authors geographically separated yet representing the best of present-day practice and academic influence, a new volume on the treatment of fractures, dislocations and sprains appears. It is a complete review of accepted methods and cannot fail to be helpful on any controversial point to the reader who seeks real information because it contains the advice of two men qualified to speak on the subject given without reserve. The print is plain, easy to read and indexed with subject headings. The size of the volume is quite overpowering, but the range of its contents may make this necessary. As an expression of the advance in the South of accepted methods of treatment, this book is excellent and its influence will do much to help the rising generation of practitioners.

Anatomie des Menschen. Ein Lehrbuch für Studierende und Ärzte. Band II. Eingeweide (einschliesslich periphere Leitungsbahnen I). Von Hermann Braus, weil. o. o. Professor an der Universität Würzburg. Bearbeitet von Kurt Elze, o. b. Professor an der Universität Rostock. Second edition. Cloth. Price 45 marks. Pp. 710 with 332 illustrations. Berlin: Julius Springer 1934.

This is well known as the textbook of anatomy that deals especially with the living working human body. It is also characterized by the way in which cognate sciences, such as embryology and comparative anatomy, are made to add to insight into human anatomy. The book consists of three volumes. Braus published the first two (Bewagungs-Apparat and Eingeweide) but died in 1924 before the third volume (Central Nervensystem) was fully prepared. Professor Kurt Elze of Rostock has succeeded Braus as editor. A second edition of volume I was published in 1929, the first part of the third volume appeared in 1932 and now the second edition of the second volume (Eingeweide) appears. It is welcomed by all students of anatomy. Professor Elze has included in this edition the results of recent research and has rewritten some parts because of new points of view. He has replaced about thirty of the original 329 illustrations with others now available and added a dozen or more new ones. These changes affect especially the sections dealing with fields in which investigation has been most active, e.g., the endocrine glands and the gonads. The publisher has produced a book which is a delight to the student. An index covering both text and illustrations has been added to this edition, and it contributes greatly to the value and usefulness of the book.

Rôle du système nerveux et des facteurs biologiques et psychiques dans l'immunité. Par S. Métalikoff. Monographies de l'Institut Pasteur. Paper. Price 28 francs. Pp. 166 with 26 illustrations. Paris: Masson & Cie 1934.

This monograph gives a clear description of defense reactions in certain unicellular organisms, invertebrates and insects. Experiments are described to show that in some cases the nervous system plays an important part in immune phenomena, which may be stimulated through the nerves without the intervention of the blood. The role of conditioned reflexes in immune reactions is considered. Following the methods of Pavlov, Metalikoff claims that he himself as well as others have shown that reactions of immunity may be produced not only by the injection of antigens in rabbits and guinea-pigs but also by the excitation of conditioned reflexes in such animals previously injected with antigens that is through the imme-

date intervention of the nervous system. The experiments described are highly interesting and while the results in antibody production from the excitation of conditioned reflexes do not seem fully convincing, the monograph will be of much interest to students of immunity.

Medicolegal

Malpractice Release of Tort Feasor as Release of Physician from Liability—The plaintiff's infant son, injured by a truck belonging to the Nassif Candy Company, was treated by the defendants, physicians employed by the father. Later the father, as guardian for his child, effected a compromise settlement with the candy company and released it from further liability. In this action, as guardian for the injured child, he sued the physicians for alleged damages attributed by him to their negligent and unskilful treatment of the child. In the trial court, the defendants contended that the release executed to the candy company released and discharged them from all liability for negligence charged against them. The trial court certified the case to the Supreme Court of Appeals of West Virginia.

The specific question for determination, said the Supreme Court of Appeals, is whether or not the release of one whose negligence causes physical injury to a person releases from liability a physician, chosen with due care by the injured person or by one acting for him, whose negligent treatment aggravates the original injury. The almost universal rule, said the court, is as follows:

It is a general rule that if an injured person uses ordinary care in selecting a physician, the law regards an injury resulting from mistakes of the physician or his want of skill or a failure of the means employed to effect a cure as a part of the immediate and direct damages which naturally flow from the original injury.—8 *Ruling Case Law* p. 449.

The law holds the person who caused the original injury liable for such damages as flow from the negligence of the attending physician, since but for that injury there would have been no such negligence. The original injury is the proximate cause of the damages due to malpractice. The original tortfeasor being liable for the full consequences of the injury, it follows that a settlement with him which releases him from all further liability operates as an acquittance of the whole matter.

The plaintiff contended however, that the candy company and the defendants were joint tortfeasors and that therefore, under section 55-7-12, Code of 1931, a release of the candy company does not inure to the benefit of the defendants, the section reading:

A release to another tortfeasor shall not inure to the benefit of another tortfeasor and shall be no bar to an action or suit against such other tortfeasor for the same cause of action to which the release relates.

While the section referred to does not use the term joint tortfeasor, said the court, the section was intended to apply to all joint wrongdoers. But, said the Supreme Court of Appeals, the authorities make it clear that under the circumstances existing in this case the relationship of joint tortfeasors does not exist—*Stachlin v Hochdoerfer* (Mo Sup), 235 S W 1060, *Fisher v Milwaukee Electric Ry & Light Co*, 173 Wis 57, 180 N W 269, *Phillips v Werndorff* (Iowa), 243 N W 525. The judgment of the trial court against the plaintiff was affirmed—*Mier v Yoho et al* (IV Va) 171 S E 535.

Insurance, Health "Necessarily Confined to Bed" Construed—The defendant company issued to the plaintiff an insurance policy providing certain benefits if the insured by reason of illness was "necessarily confined to bed." The plaintiff had a severe case of chronic bronchial asthma. The company paid him the agreed benefits for the first week but refused to make further payments contending that his illness did not necessarily confine him to bed. The plaintiff brought suit but at the close of his testimony the trial court dismissed the case, holding that the evidence showed that the plaintiff was not actually confined to his bed during the time for which he

sought to recover benefits. The plaintiff thereupon appealed to the Supreme Court of South Carolina.

The evidence showed that the plaintiff had been a "bed patient" practically all of the time for which benefits were sought. The plaintiff testified, however, that he had not been in bed all the time, as he felt easier when he was up, that he had walked some—short distances—and that he had gone to the office of his physician at times to see him. In the numerous cases, said the Supreme Court, in which the words "confined to the house" and "confined within the house" have been construed, it has been generally held that such clauses should be given reasonable construction and that recovery may be had where there is a "substantial confinement to the house," although the insured may have gone out of the house to get air or sunshine or to see his physician, or for some other necessary purpose. With respect to the clause "confined to bed," in *Bradshaw v Association*, 112 Mo App 435, 87 S W 46, the court said:

We would not of course hold that this clause meant that a patient must stay every minute in bed for his right to indemnity to accrue but the manifest purpose of the policy was not to indemnify for loss of time due to sickness unless the patient was bedridden in a substantial sense.

Again, in *Hays v Association*, 127 Mo App 195, 104 S W 1141, the court held that the insured was "entirely and continuously confined to bed," within the terms of a health policy, when he was confined to bed the greater portion of the time every day during his sickness, although at times he sat outside the house, was once driven a few blocks, and was in and out of bed many times. In *North v Insurance Company* (Mo App) 231 S W 665, the policy provided that the weekly benefits would be payable if the insured by reason of illness was necessarily confined to bed. The evidence in that case showed that the insured suffered from heart trouble and that at times she was unable to lie in bed, her ailment being such that she could not get her breath while in a reclining position. The court in that case observed:

Under the facts in this case it would be rank nonsense to hold that because the insured could not lie in bed owing to the bad condition of her heart she was not entitled to such benefits. That provision of the contract heretofore set out does not mean that the insured should be confined to bed all the time but means that the insured must be bedridden in a substantial sense.

And again in *Home Protective Association v Williams*, 151 Ky 146, 151 S W 361, Ann Cas 1915A, 260, the Kentucky court approved the following instruction:

The insured was necessarily and continuously confined to bed if his sickness was such as would reasonably confine a person continuously to bed or substantially so confine him though he may have been up at times to get fresh air or for other purposes.

In the present case, said the Supreme Court, the trial court took the view that although the insured was seriously afflicted with asthma his testimony that he was not regularly in bed would defeat as a matter of law, his claim for sick benefits under the policy. In the opinion of the Supreme Court, however, it was for the jury to say, under all of the evidence in the case, whether the plaintiff was bedridden in a substantial sense and the trial court committed error in not submitting that question to the jury under proper instructions. The judgment of the trial court was therefore reversed and the case remanded for a new trial—*Peace v Southern Life & Trust Co* (S C) 171 S E 475.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to *THE JOURNAL* in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Dextrose Therapy in Cardiac Disease—Smith and Luten report sixteen cases of heart failure in advanced heart disease in which an opportunity was afforded for the comparison of the effects of dextrose and digitalis. In nine cases dyspnea was relieved to some extent by dextrose. The effect, however, was of short duration (from three to twelve hours) as compared with the more lasting effect of digitalis. Dextrose failed to restore compensation in any case. Digitalis restored compensation in three cases. The first injection of dextrose seemed to have a more beneficial effect than subsequent ones. Accordingly, dextrose therapy appears to be indicated as an emergency measure in cases of acute or urgent heart failure and in cases of advanced chronic heart failure in which digitalis in adequate amounts has not restored compensation.

Duration of the Phases of Diastole—Bohning and Plaut measured the duration of each of the separate phases in approximately 1750 cardiac cycles in fifty subjects fifteen of whom had normal hearts the remaining thirty-five having some type of cardiac lesion. In auricular fibrillation total systole was found to be definitely shorter and total diastole definitely longer than in normal subjects. In all the other types of cardiac derangement total systole was longer and total diastole shorter than in normal subjects. In digitalized cases of auricular fibrillation the isometric relaxation and the phases of rapid inflow tended to be prolonged. In aortic regurgitation protodiastole tended to be prolonged isometric relaxation to be shortened and auricular systole to be slightly prolonged in comparison to the duration of these phases in normal hearts.

Insulin in Treatment of Peptic Ulcer—Jones administered from 10 to 15 sometimes 20 units of insulin subcutaneously fifteen minutes before eating to twelve patients having recent peptic gastric ulcers six patients with recurring ulcers and eight patients presenting complicated ulcers in the sense of Treitzky's theory. The action was not immediate but usually in from four to five days of insulin treatment there was a decrease of the pain improvement in the subjective condition and an increase in weight which was coincident with a decrease of the vagotonus. In seven of the twelve patients of the first group pain disappeared after five days and the blood from the contents of the gastro intestinal tract after seven days in spite of the distinct increase of the gastric secretion. In four persons the symptoms disappeared in from six to ten days in one patient the feeling of complete well being appeared only after two weeks. The weight of all patients increased from 3 to 8 pounds (13 to 36 Kg). In the second group of six patients insulin treatment (from 20 to 30 units daily) carried

Effect of Radiation on Growth of Carcinoma and Sarcoma—In order to determine the minimal lethal doses for Flexner-Jobling carcinoma and Sugiura sarcoma Sugiyama and Benedict studied the effect of radiation from filtered radon implants on the growth of the carcinoma and sarcoma in rats. In the case of Flexner-Jobling rat carcinoma, tumors 2 cm or less in diameter showed complete regression in about 50 per cent of the cases with from 2 to 3 skin erythema doses. With more than 3 skin erythema doses, tumor regression occurred in 90 per cent of cases in which the masses were not more than 2 cm in diameter. Larger tumors, from 24 to 33 cm in diameter, were seldom destroyed even by relatively large doses of radiation (about 6 skin erythema doses). For early stages of Sugiura rat sarcomas measuring from 0.7 to 1.5 cm in diameter, less than 3 skin erythema doses would not produce regression in as many as 50 per cent of the cases. On the other hand slightly higher doses, from 3 to 4 skin erythema doses produced regression in about 80 per cent of all tests. In destruction of the sarcoma was insufficient for the complete destruction of the sarcoma. With a much larger dose (about 6 skin erythema doses) similar large tumors could sometimes be destroyed completely.

out for two to three weeks, gave good results, so that roentgen examination revealed no signs of the previously existing ulcer. Four of the patients were observed for nine, eleven, thirteen and fifteen months, respectively. No recurrences were observed. In one patient there was a recurrence after five and one-half months, the ulcer symptoms disappeared again after ten days of insulin treatment. The last group of patients experienced undoubted relief under the influence of from fourteen to sixteen days of insulin treatment the pains, although considerably lessened, continued to recur from time to time, especially in the periods of nondigestion, apparently correlating to movements of the stomach. Nevertheless, the patients stated that their well being was improved greatly. They gained in weight and had good appetites, two of them, after leaving the hospital, could do physical work of which they had been incapable before.

Hematogenous (Nonmiliary) Pulmonary Tuberculosis

—Pinner draws attention to a type of pulmonary tuberculosis that is most likely caused by hematogenous seeding and does not take the course of miliary tuberculosis. The roentgenologic characteristics are fairly evenly and symmetrically scattered shadows of slight density and of blurred outlines, which undergo one of the following changes disappearance (resorption), increase in density (fibrosis or calcification) or coalescence, terminating in the usual manifestations of bronchogenic phthisis. Clinically these cases are frequently, but not always characterized by an astounding paucity of symptoms and sometimes of physical signs as well in spite of massive anatomic involvement and by the difficulty of demonstrating tubercle bacilli in the sputum. The anatomic and histologic characteristics include the more or less even seeding throughout both lungs (and frequently in extrapulmonary organs) the frequent absence of larger cavities, the absence of apparently old upper lobe lesions, the frequent evidence of repeated seedings and the type of healing. Histologic studies would indicate that the major part of the pathologic processes occurs in the interstitial tissue.

Congenital Cardiac Disease in Infants—Pendergrass and Allen observed tracheal displacement in the inspiratory phase in nine cases of congenital heart disease. Necropsy showed complete transposition of the great vessels in two cases, partial transposition of the great vessels in two cases, dextroposition of the aorta in one case, complete transposition of the heart and the great vessels in one case and multiple intrinsic defects in the heart in three cases. In 150 normal infants, tracheal displacement did not occur in the inspiratory phase. Displacement of the trachea due to an enlarged thymus often gives an appearance similar to that seen in these cases. Anatomic and postmortem evidence suggests that transposition of the great vessels may have been responsible for the tracheal displacement in most of the authors' cases. The possibility of some other mechanism causing tracheal displacement in these cases should be borne in mind, since several of their cases did not present transposition of the vessels. The average patient with tracheal displacement has a congenital lesion of sufficient magnitude to be diagnosed clinically. The authors have no conclusive data as yet which would suggest that tracheal deviation is pathognomonic of congenital heart disease in the absence of clinical signs.

Treatment of Cancer with 600 Kilovolt Roentgen Therapy—During the past three years, Mudd and his associates treated 285 cancer patients with 600 kilovolt roentgen therapy. They describe the technique of moderately heavy protracted irradiation used in the treatment of malignant lesions of the bladder, prostate, rectum, esophagus, larynx and pharynx. They have made comparisons of the cutaneous reaction subsequent to treatment with 200 kilovolts with 0.5 mm of copper filter and 600 kilovolts with 5 mm of steel filter, as well as with 1 mm of lead additional filtration. They discuss time factors involved in the production of erythema as well as roentgen doses that have led to serious roentgen dermatitis. They noted that persons in good general physical condition withstand short wavelength roentgen therapy with little discomfort. The results of gross and microscopic pathologic examinations are briefly discussed. There have been many instances of palliation in patients able to withstand full cycles of high voltage roentgen therapy. In the authors' opinion, heavily filtered radiation at 600 kilovolts or higher seems to offer better possibilities in the treatment of certain types of deep seated cancer than radiation at substantially lower voltage. The results achieved by its use may be favorably compared to the effects produced by a 4 gram radium pack.

Primary Tumors of the Ureter—A search of the literature revealed only sixty-eight cases of primary malignant tumors of the ureter including the three that Lazarus reports. The nonpapillary type of tumor comprised 42 per cent of the series. Malignant tumors of the ureter are most frequently found in the lower part of the ureter and are associated with hydronephrosis in 67 per cent and hydro ureter in 51 per cent of the cases. The disease occurs during the sixth and seventh decades in 50 per cent of the cases. The growth is invasive and metastasizes readily to the regional lymph nodes (48 per cent) lungs (18 per cent) and liver (22 per cent). Although pain, hematuria and enlargement of the kidney constitute the characteristic triad of symptoms, it was found that hematuria alone was the principal symptom in 75 per cent of the cases. The diagnosis can be made only by carefully executed cystoscopic roentgenographic procedures. The presence of a tumor at

the ureteral orifice is a highly suggestive observation, yet it was reported in only 29 per cent. A definitely established filling defect in the ureterogram is the only pathognomonic sign of a tumor of the ureter and was reported in only 8.7 per cent. The infrequency of this finding is probably due to the failure to suspect the lesion and consequently to the failure of carrying out carefully made ureterograms. The encountering of an obstruction in the ureter, as occurred in 38.2 per cent, provocation of bleeding by manipulation of the catheter, and failure to demonstrate a shadow suggestive of calculus at the site of obstruction on the roentgenogram, should suggest the possibility of this condition. The author is of the opinion that repeated attempts at ureterograms in such cases would eventually demonstrate a filling defect in a greater proportion thus confirming the diagnosis of ureteral neoplasm. Owing to the difficulty encountered at times of palpating the tumor within the ureter at the time of the operation, it seems better in those cases in which operation is undertaken for the purpose of exploring the upper urologic tract for hematuria, especially when a tumor of the ureter is not suspected to do a complete ureterectomy with the nephrectomy in the event that the kidney fails to account fully for the bleeding. The procedure of choice in the treatment of this disease is complete nephro-ureterectomy by the extra-peritoneal approach, the resection including a portion of the bladder adjacent to the ureteral meatus. The operation is best done under spinal anesthesia and is concluded by placing an indwelling catheter into the bladder through the urethra. It is retained for a week or ten days.

Pituitary Basophilism.—Pardee outlines five syndromes of pituitary basophilism: the Cushing syndrome, a mixed syndrome of intrasellar pituitary disease, a syndrome in which the disturbances appear to point to involvement of the supranuclear cortex, a prepubertal or pubertal basophilic syndrome and the postmenopausal basophilic syndrome. He endeavors to confirm the characteristic syndrome of pituitary basophilism described by Cushing and to demonstrate that not all basophilic syndromes are necessarily progressive and fatal, likewise that pituitary adenomas presenting many features of this syndrome exist, and are either purely pituitary basophilism or combined with acidophilism and disease of the suprarenals; also that transitory or mild degrees of pituitary basophilism (Cushing) do exist not only in adolescents but in premenopausal and postmenopausal states. The author believes that the close relationship of the hypophysis to the gonads is no doubt an important factor in producing a predominant activity of the basophil cells because this syndrome occurs more frequently in women. It has been affirmed that the basophil cells produce the gonad-stimulating hormone of the hypophysis (anterior lobe). This is an assumption that is not yet well founded and will probably be altered on both experimental and practical grounds. Two of the author's cases showed an absence of anterior pituitary-like principle in the urine, as did one of Cushing's cases. These patients present every evidence of underactivity of the sex function rather than a stimulatory effect. One will have to fall back on a theoretical explanation which presumes that a proper balance between the endocrine organs has been disturbed, resulting in a pluriglandular disorder; the principal feature of which is the basophilic syndrome.

Convulsions of Undetermined Etiology.—Nielsen presents fifty-eight consecutive dextrose tolerance curves in cases of idiopathic epilepsy and shows that periodic or constant low blood sugar occurs in about 90 per cent of epileptic persons during a dextrose tolerance test. A series of 182 dextrose tolerance curves in various types of patients is analyzed to determine whether those with epilepsy, as a class, show lower readings. The syndrome of idiopathic epilepsy seems to be for the greater part confined to persons with a tendency to hypoglycemia but except in rare instances hypoglycemia itself is not sufficient to cause an epileptic attack. Other necessary factors probably are hydration, alkalosis, depletion of glycogen, hypoadrenalism or imbalance of the vegetative nervous system. The author agrees with Munch-Petersen and Schou that the hypoglycemia rather serves to indicate the type of person with which one is dealing. However, hyperinsulinism cannot be detected and separated from idiopathic epilepsy by the determination of blood sugar during fasting. It cannot be differentiated even by a dextrose tolerance test. Clinical data of other sorts are necessary.

Carcinoma of the Thyroid.—Lee reports a case of carcinoma of the thyroid in a child aged 8 years, in whom the diagnosis of Riedel's thyroiditis was made on the basis of a small firm uniformly enlarged gland. A severe attack of gonococcal vaginitis occurred while the child was in the hospital and apparently after the enlargement of the thyroid had been noted. At operation the ribbon muscles of the neck were found adherent to the gland and the disease was considered to be an inflammatory process. Not enough weight was given to the presence of two small masses in the left side of the neck, which were indicative of a malignant process and are not usual in cases of Riedel's thyroiditis. Another curious condition was

the sudden increase in size in the two small masses in the neck following the first operation. In view of the diagnosis of carcinoma it was natural to suspect that this enlargement was a rapidly growing metastasis, but since the original tumor in the thyroid had grown slowly, a growth of metastasis so sudden and rapid was not looked for, even though operative intervention promotes metastatic development. The masses in the neck became smaller following tonsillectomy.

Insulin Therapy in Mental Patients—Sharp and Bahr studied the effect of insulin therapy in three cases of dementia praecox (two of the catatonic and one of the simple type), one case of involutional psychosis and one of manic depressive psychosis in the depressed phase. Three of the patients were eating but little and two were on actual hunger strikes. All of them were thin and emaciated. The insulin was given three times daily in 10 unit doses, thirty minutes before meals and no change was made in the routine of the patients. Definite increases in weight and strength were noted after four weeks of insulin therapy, but some of this was lost in the two months following the cessation of the treatment. The authors believe that this was due to the mental states, viz. negativism in the three praecox cases and the depressed melancholic state in the cases of involutional psychosis and manic-depressive psychosis. Gastro-intestinal roentgenograms tended to show some improvement in the emptying time of the stomach and colon. However, the results were not striking. The extremely low stomach acidity in all the cases was striking and seemed to be parallel with the negativism. The mental state improved in only the manic-depressive patient.

Rickets in Rats by Iron Feeding—Brock and Diamond produced rickets in rats by the addition of ferric chloride to a normal, nonrachitogenic diet. The rickets so produced, as judged by roentgenographic, microscopic and chemical studies, was qualitatively similar to but more severe than that produced by Steenbock's rachitogenic diet 2965. The addition of phosphorus to this ferric chloride diet prevented the occurrence of rickets. The chlorine radical of the ferric chloride has been eliminated as the rachitogenic factor by negative results from the addition of ammonium chloride to the nonrachitogenic diet. Similar rachitic changes have been produced by the addition of other iron compounds to the nonrachitogenic diet.

Acrodynia—Wolf and Davison report a case of acrodynia in a child aged 2 years, who presented the typical trophic changes. Histopathologic study of the nervous system revealed

a marked swelling of the ganglion cells of the third cortical lamina, the large ganglion cells of the neostriatum and the Purkinje cells of the cerebellum, and severe pathologic changes in the nerve cells of the locus ceruleus. In the cervical region of the spinal cord there was some disintegration of the fibers in the ventrolateral tracts and loss of Nissl substance and vacuolization in the motor cells of the nucleus ventralis of the eleventh nerve, and in the ventrolateral and ventromesial anterior horn cells. The peripheral nerve changes were similar to those seen in peripheral neuritis.

Effect of Exercise Following Atelectasis and Pneumonectomy—Drastich and his associates draw the following conclusions from their experiments on dogs: 1. Reduction in active pulmonary tissue by 50 per cent does not embarrass the organism when engaged in moderate exercise, such as running on a level. 2. More strenuous exercise such as swimming results in more fixed acid production than normal. This probably is to be interpreted as indicating that the tissues are receiving a less than normal supply of oxygen and incomplete oxidation results. A decreased percentage saturation of the blood with oxygen in some instances would tend to favor such an explanation although these results are too incomplete to provide conclusive proof. 3. The elimination of carbon dioxide appears to proceed with normal efficiency unless as much as 75 per cent of the active pulmonary tissue is removed. Even then severe exercise seems to be well tolerated. 4. When the active pulmonary tissue was reduced by equal amounts, fixed acid increase was more marked in animals with partial collapse than in those with partial pneumonectomy, suggesting that a significant fraction of the blood flows through the atelectatic tissue.

Thoracoplasty—The clinical study of Gale indicates that the prone position possesses definite advantages in the performance of extrapleural paravertebral thoracoplasty. In his experience the most desirable type of anesthetic agent during the operation is the nitrous oxide ethylene sequence. Pericostal sutures employed during the second and third stages of a thoracoplasty are effective by reducing the transverse diameter of the hemithorax as a unit and afford a method of preventing paradoxical breathing in patients with a thin pleura. The author recommends the use of intrapharyngeal oxygen as a routine measure following thoracoplasty. It guards against anoxemia which if not treated will draw heavily on the patient's reserve. The use of blood transfusion before and between operative stages furnishes an effective therapeutic measure. Wound infection should be treated by early adequate drainage, otherwise the purpose of the operation may be defeated.

Treatment of Tuberculous Empyema—Rosenblatt presents the end results in a series of twenty-one cases of toxic tuberculous empyema treated conservatively and followed up for from three and one-half to eleven years. The principles underlying the treatment depend on the number of complicating factors present. The therapeutic measures commonly employed in tuberculous empyema may be classified as conservative and radical. The conservative measures frequently used are aspiration, aspiration and air replacement, aspiration and irrigation

with antiseptic solutions, such as sodium chloride, gentian violet, acriflavine and potassium permanganate, and oleothorax with a 5 to 10 per cent solution of aromatized oil. The treatment in the author's cases consisted of aspiration of as much of the pus as possible, replacing it with air, and the injection of from 2 to 3 cc of a saturated alcoholic solution of methylene blue just before the needle was withdrawn. This treatment was repeated at varying intervals, depending on the rapidity with which the fluid reaccumulated. The amount of air introduced was dependent on the amount of fluid aspirated and the intrapleural pressure. In large effusions with a free pleural cavity, a slightly negative pressure was left at the end of the treatment. If the pleural cavity became limited and further collapse of the lung was desired, enough air was introduced to produce a slightly positive pressure. This procedure was repeated periodically, as long as there was any fluid that could be aspirated, though the intervals between treatments could be gradually increased as the reaccumulation of the pus became slower. The successful cases remained under treatment for from eight months to four years. The average length of treatment was approximately two years. Eleven patients were cured and ten died. Of the cured patients, ten are entirely free of symptoms and are able to work, and one is under treatment with pneumothorax for a newly developed lesion on the opposite side but the empyema has entirely cleared up and the lung re-expanded. Among the patients who recovered two developed empyema as a result of perforation of the lung, and of these two, one had also a fair-sized bronchopleural fistula. One patient with a small draining sinus in the chest wall and a small intermittently patent bronchopleural fistula also recovered. In this case the sinus persisted for about two years and has been healed for the last three years. Of the patients who died, four showed considerable improvement temporarily, and the ultimate fatal outcome was due to the progressive pulmonary disease. Six failed to show improvement. The empyema was probably an important factor in the unfavorable outcome of three cases. In two of these, large bronchopleural fistulas were present.

Unique Operation for Appendicitis—Preoperatively, in appendectomies in adults, Myatt uses one-fourth grain (0.016 Gm) of morphine sulphate and $\frac{1}{160}$ grain (0.0004 Gm) of atropine sulphate. For anesthesia he uses straight nitrous oxide oxygen gas and feels that this is a marked advance over ether or spinal anesthesia. His incision measures from 2 to 5 cm in length and runs almost transversely across the abdomen in the natural skin fold, so that when it is healed there is no pulling apart of fibers. The fascia of the external oblique muscle is nicked with a scalpel, the handle of the scalpel is inserted and the fascia is separated with no cutting across the fibers. A small retractor is inserted under the mesial edge of the fascia and a slight nick is made in the internal oblique muscle. The handle of the scalpel is again inserted and the internal oblique and transversalis muscles are separated, thus exposing the peritoneum. The peritoneum is freed and loosened by sweeping the finger around. A narrow rather long retractor of the Deaver type is inserted after the peritoneum is opened and retracted mesially. This draws the small intestine toward the midline and the blue cecum is often visible. This is brought up with the finger or a clamp until the appendix comes into view. The cecum is then replaced in the abdomen, the meso-appendix is clamped and tied serially, and a linen purse string suture is placed about the appendix with a small cutting-edge straight needle. The appendix is girdled, crushed, clamped,

ligated, cut and treated with phenol alcohol. It is then grasped with mosquito forceps and, after the ligature is cut about the base of the appendix, the stump is inverted and closed with the linen purse string suture. In closing the peritoneum a continuous suture, one or two interrupted sutures for the muscles, fascia and subcutaneous tissues and Michel clips for the skin are used. The tiny incision is usually employed in young adults with no evidence of other pathologic manifestation and in women the uterus, right tube and ovary can be palpated.

Strictures of Rectum Due to Lymphogranuloma Inguinale—Bloom points out that a certain group of rectal strictures of obscure etiology is due to a previous infection with the virus of lymphogranuloma inguinale and that lympho-

granuloma inguinale resembles in many respects the conditions described in the literature as "benign" or "inflammatory" strictures of the rectum. The uncertainty about the etiology of these strictures equaled until lately the uncertainty about the etiology of the strictures associated with the syndrome of esthiomene and anorectal syphiloma. The patients usually give a history of anal fistulas, mucopurulent and bloody discharge from the rectum, painful defecation and finally obstinate constipation. In the beginning there is only discharge from the rectum, later, pain and symptoms of stenosis appear which are extremely obstinate to treatment. The patients are frequently admitted to the hospital with the diagnosis of cancer of the rectum. After the pathologic examination eliminates malignant changes the diagnosis of syphilitic stricture frequently is made even in the absence of a history of syphilis. Because of the obstinacy and resistance to treatment, serious operations are carried out. It may be seen how closely the benign rectal strictures resemble the foregoing strictures in association with genito-anorectal elephantiasis and one may readily conclude that these strictures are identical. In the last few years it has been proved that lymphogranuloma inguinale is the etiologic factor in the production of these benign or inflammatory strictures as well as the syndrome of genito-anorectal elephantiasis. It was proved by the frequent history of the characteristic lymphogranuloma inguinale adenitis and particularly by the positive Frei test.

Complete Laceration of the Perineum—Johnson discusses the nature of the construction of the external sphincter and describes a method for its reconstruction in complete laceration. He states that the dimple on the perianal skin represents not only the 'scar tissue envelopment' at the end of the muscle but also the torn fascial and tendinous insertion of the sphincter muscle belly. The first step necessarily, is the use of the tissue in the dimple in the division of the sphincter muscle. This is done by passing a number 4 catgut suture on a heavy full curved cutting needle through the full depth of both dimples, and then tying them securely approximating the dimples. This suture, being large has a great primary tort and it will not tear through the fascia, the muscle or the thin anal skin. Then, with the rectal dilator, the muscles are slowly and carefully stretched and the suture is cut and withdrawn. This dividing procedure paralyzes the muscles for a period of about ten days, and soon the muscle assumes its original tone. By means of the Barrett method of perineal repair, denudation is done. The torn or separated fibers and fasciae of the levator ani, the bulbocavernosus, the transversus perinei and the internal sphincter are then dealt with in the customary manner, and lastly the fascial ends of the sphincter muscles are carefully isolated. Since all voluntary muscles have fasciotendinous terminations, any denudation or baring of the muscle ends may entirely destroy the function and power of the muscles. Hence the fascial and connective tissue cap on the ends of the muscles should be left untouched. The ends of both muscles are then picked up with a hard chromic number 1 catgut suture and the suture is carried through twice on both ends and tied securely. After the excess of vaginal mucosa is cut away, the subcuticular tissues are sutured with interrupted chromic sutures and, finally, the mucosa of the vagina and the skin are likewise approximated.

The Great Vein of Galen and Increased Intracranial Pressure—Bedford questions the authenticity of the two cases of hydrocephalus that Dandy considers to have been caused by obstruction of the great vein of Galen or of the straight sinus, and advances evidence to prove that no indisputable case of hydrocephalus following thrombosis of these venous channels has been reported. He describes the arrangement and communications of the veins of the velum interpositum in the dog and states that they are not identical with those found in man. Following the occlusion of any portion of the great vein of Galen, collateral circulation is rapidly established. The choroid plexuses remain unchanged in their gross appearance. In the dog, hydrocephalus does not follow experimental occlusion of the great vein of Galen. He suggests that the hydrocephalus found occasionally by Dandy and Blackfan and by Guleke in dogs in which the great vein of Galen had been occluded was not due to the obstruction of the vessel. It is easily explained as originating in a form of meningo-encephalitis that leads to an obstruction of the normal circulation of cerebrospinal fluid at the base of the brain.

Hour-Glass Tumors of the Spine—Cohen encountered three cases of so-called hour-glass or dumb-bell tumors in a series of forty-two cases of compression paraplegia due to tumors of the spine or spinal cord. This type of tumor may arise at any level of the spine. They may arise intraspinally and grow outward through an intervertebral foramen or rarely between the laminae, forming an extraspinal portion, or they may arise extraspinally and extend through an intervertebral foramen, forming an intraspinal prolongation. The tumors may arise from any tissue—the membranes, nerves, ganglions, sympathetic nervous system, ligaments, cartilage, bone or fat, but a large number of them are fibroblastogenic or neurogenic and originate from the meninges, ganglions or nerve roots. The great majority are benign encapsulated growths though a few are definitely malignant. The usual symptomatology of spinal compression accompanied by changes in the pressure and the chemistry of the cerebrospinal fluid may be present, with frequent and severe root pain resulting from the situation of the tumor, a palpable lump may be found in the cervical region and occasionally in the lumbar region and symptoms such as pain on movement or rigidity may be caused by vertebral damage. Acquaintance with the lesion is primarily essential for its recognition. In order to prevent recurrence of the tumor, both intraspinal and extraspinal portions must be removed. Many cases of recurrence are caused by the nonrecognition of the extraspinal portion. The initial attack should be on the intraspinal portion.

Cerebrospinal Fluid in Multiple Sclerosis—Merritt studied the cerebrospinal fluid in 100 cases of multiple sclerosis and summarizes the observations in 968 previously reported cases. He found that the cerebrospinal fluid is normal in less than 20 per cent of cases of multiple sclerosis. The intracranial pressure is usually normal but may occasionally be slightly elevated. A pressure greater than 200 mm of cerebrospinal fluid is practically never found. Pleocytosis of a moderate grade (from 6 to 40 cells per cubic centimeter) occurred in 28 per cent of the recorded cases. A quantitative abnormality of the protein content of the fluid was present in 45 per cent of the cases. A quantitative increase in the protein content above the normal limit was present in 24 per cent. An abnormal colloidal gold curve was present in 71 per cent. The fluid is

usually normal in regard to its chloride, dextrose, nonprotein nitrogen, calcium, phosphorus, sodium, total solid content and freezing point. The cerebrospinal fluid Wassermann reaction is always negative. There is a rough degree of correlation between the clinical course and the observations on the cerebrospinal fluid. A higher proportion of abnormalities is found in the fluids of active cases than in the fluids of stationary cases. A pleocytosis of more than 10 cells per cubic millimeter or coincident abnormalities in cells, protein and colloidal gold occur only in progressive cases. There are no changes in the cerebrospinal fluid that are pathognomonic of multiple sclerosis. The presence of a first or midzone colloidal gold curve with or without a slight pleocytosis and increased protein content, in an otherwise normal fluid is supporting evidence for the diagnosis of multiple sclerosis in a clinically suggestive case provided there is no history of syphilis or of antisyphilitic treatment.

Review of Ewing's Tumor—Lattman states that a biopsy of Ewing's tumor should be done only in the cases in which the radiation test fails. A biopsy is of no more practical value than the radiation therapeutic test and it needlessly increases the hazard of early metastasis. The disease is as a rule, confined to persons under 30 years of age. Men are more susceptible. The tumor involves the middle of the bone and a considerable portion of the shaft rather than the end. The epiphysis is never involved. The tumor causes a diffuse destruction of the bone, both cortical and central. It may also cause a limited amount of bone formation. Early in the disease the roentgenogram shows a widened cortex of increased density. Later in the disease the roentgenogram may show the "onion-skin-like" appearance considered by some as pathognomonic. The tumor is highly roentgen sensitive, a fact of prime importance in its diagnosis and treatment. The author gives reports of three cases.

Treatment of Gonorrhea in Women—Statham treated 158 cases of gonorrhea in women by swabbing with a 1 per cent solution of mercurochrome. The criteria of cure are three consecutive sets of smears from cervix and urethra, taken month after the usual menstrual period, also a negative culture.

from the same regions and a negative complement deviation test for gonorrhea. A final test in which smears, cultures and a complement deviation test are repeated is performed three months later. The reliability of this method is shown by the low incidence (five cases) of recurrence and the fact that a number of these patients were attending the gynecologic outpatient department at varying intervals after treatment, although none have ever given a positive result since treatment was stopped. Complications were noted in thirty-five cases (large erosion of cervix, salpingitis, Bartholinitis, acute cystitis, rheumatism and eye symptoms), the other 123 patients made an uninterrupted recovery.

Ephedrine Sulphate in the Prevention of Stokes-Adams Seizures—Gilchrist observed that ephedrine taken orally increased the ventricular rate in four of six cases of complete heart block. In two cases the test was indecisive. Barium chloride produced no demonstrable effect on the ventricular rate in the four cases responding to ephedrine. It did no harm in doses larger than those originally recommended. In two cases of complete heart block, complicated by occasional Stokes-Adams seizures, ephedrine taken for two and a half and one and a half years, respectively, proved entirely successful in the prevention of syncopal attacks. When the drug was discontinued typical seizures returned. The author recommends that the dose of ephedrine should be the minimal quantity consistent with an acceleration of the resting ventricular rate. Larger doses may cause overstimulation. If the drug is then omitted suddenly profound slowing of the ventricular rate with repeated Stokes-Adams attacks may occur, as a result, presumably of exhaustion of the idioventricular center. A dose of one-half gram (0.032 Gm) by mouth at intervals of eight hours may be sufficient. In the absence of positive observations it is difficult to credit barium chloride with the power of preventing Stokes-Adams seizures.

*Ketone Content of the Blood in Labor and Preeclamptic Toxemia Note D F Anderson—p 261

Endometriosis Vesicae—Phillips believes that although endometriosis involving the bladder is one of the rare types of the disease its incidence is far greater than has been assumed. The cystoscope should be used more frequently for diagnosis. The possibility of endometriosis of the bladder should always be considered in a patient presenting frequency of micturition,

dysuria and hematuria. When this triad is cyclic and is exacerbated during the menstrual period and the cystoscopic examination shows blue-black cysts and endometriotic edema the diagnosis of endometriosis of the bladder is verified. The method of choice in the treatment of vesical endometriosis is the roentgenologic induction of an artificial menopause. Surgical intervention, however, is indicated in those few cases in which the patient is considerably under the age of the menopause and desires children.

Ketone Content of Blood in Labor and Preeclamptic Toxemia—Anderson states that while it does not seem necessary to resort to routine estimation of the acetone and diacetic acid in the blood of patients in labor, such an analysis may yield valuable information if labor is unduly prolonged. It is important to recognize that severe muscular effort takes place at this time and to take measures to prevent the development of acidosis by ensuring that the patient receives adequate, although necessarily limited nourishment. Barley sugar sucked regularly throughout the duration of labor is an efficient prophylactic. The information afforded by estimation of the blood acetone and diacetic acid in cases of toxemia of pregnancy does not justify the routine use of this examination. The high values obtained, however, would focus attention on the inadequacy of the diet, often limited to fluids, in many cases of albuminuric toxemia. Even if protein is restricted, a sufficient supply of carbohydrate ought to be ensured. A plea is made for the prevention or amelioration of edema by an adequate intake of easily assimilable protein, such as milk, since an increase of the blood urea or nonprotein nitrogen levels is not noted in cases of preeclamptic toxemia.

Treatment of Tetany—Snapper used an isolated portion of viosterol that does not contain vitamin D (A T 10 [Holtz]) in three cases of tetany, one idiopathic and two parathyropenic. The blood calcium did not exceed 6 mg per hundred cubic centimeters in any of them. Treatment was begun by giving 10 cc of A T 10 on the first day and 5 cc on the second and third days. Thereafter from 1 to 2 cc was given daily for a short time. In all the patients the calcium content of the serum increased considerably after three to five days and the symptoms of tetany disappeared. After the first ten days a dose of from 1 to 2 cc three times a week was usually sufficient to keep the calcium content normal. All other therapeutic measures could be stopped a day or two after the beginning of the A T 10 treatment. This oral method of handling tetany can be applied only in cases in which the calcium content of the serum can be watched, as otherwise there is a risk of accumulation.

Gonococcal Infection of the Kidney—Okada presents
 two cases of gonococcal infection of the kidney He believes
 that if the urine is distinctly turbid and much albumin
 is present without bladder symptoms in the course of gonor-
 rhea the gonococcal infection of the kidney is doubtful Many

intracellular gonococci were observed in the urine from the
 gonococcal kidney The number of the organisms decreased
 in the period of convalescence and finally disappeared The
 histologic examination of the organs obtained at necropsy in
 one case showed typical glomerulonephritis and formed abscesses
 in the spleen, liver and endocardium and the kidney The
 other patient presented symptoms of gonococcal nephritis and
 recovered in two months

 Glossina Palpans L van Hoof and C Henrard—p 109

Intracarotid Treatment of Congo Trypanosomiasis—
 Mora reports thirty-one cases of Congo trypanosomiasis in
 which more than 100 carotid injections were given, most of
 them in the wilds by practitioners who had no other equipment
 than a table, an ordinary syringe and an injection needle The
 technique, which was studied at the hospital of St Paul at Loanda,
 is practicable for all physicians and is painless and without
 danger It is nevertheless advisable to avoid more than three
 or four punctures of the same artery to prevent induration
 of the walls of the vessel The toxicity of certain medicaments
 such as methenamine and tryparsamide, does not seem to be
 greater by the intracarotid than by the intravenous or sub-
 cutaneous route This statement does not apply to the drugs
 having a congestive action on the brain, such as mercurochrome
 and quinine In cases of Congo trypanosomiasis presenting
 predominant cerebral symptoms the intracarotid route should
 be favored for the introduction of trypanocides especially
 tryparsamide The procedure is especially useful in treatment
 of ocular disorders occurring in the course of trypanosomiasis,
 provided the final lesion has not become established The
 author believes that ocular disorders in trypanosomiasis are
 probably caused by irritation produced by the presence of the
 trypanosomes themselves

Visual Disorders in Trypanosomiasis—The statistics of
 Van Den Branden and Appelmans showed that 20 per cent of
 a group of 118 patients suffering from trypanosomiasis who
 reached the second stage of the disease and were treated with
 tryparsamide presented visual disorders during the course of
 treatment This percentage is however, inconstant since in
 another group of sixty-nine patients only 58 per cent showed
 ocular disorders Ocular symptoms are more frequent among
 those in whom the cerebrospinal fluid is the most profoundly
 altered This is a serious sign for it demands cessation of
 arsenical treatment, rendering the prognosis less favorable The
 origin of visual disturbances appears to be complicated First
 there is an alteration of the nervous system and of the visual
 apparatus by the trypanosomes Then follows the toxic action
 of tryparsamide and the endotoxins liberated by the massive
 destruction of trypanosomes Ocular disturbances caused by
 atoxyl in chronic trypanosomiasis progress to blindness in spite
 of the interruption of treatment Those arising during the
 course of treatment with tryparsamide are serious but usually
 cease to progress if the arsenical injections are stopped imme-
 diately The visual apparatus is the touchstone or the nervous
 system from the arsenical standpoint because the least change
 is shown by disorders of visual acuity and of the visual field
 These are easily noted by either the physician or the patient

- Treatment of Addison's Disease by Cysteine J de Leobardy and A Labesse—p 599

Sodium Nitrite and Sodium Thiosulphate for Hydrocyanic Intoxication—The normal animal has some ability to detoxify in the presence of cyanide poisoning. The toxic effect is the result, therefore, of the quantity of poison absorbed per kilogram weight and per minute and the coefficient of detoxification. Since the first can be modified only under experimental conditions, Hug proposes a classification of antidotes that may modify the course of the intoxication. The first group is the reducing sugars, such as diacetyone, the second, the methemoglobin forming substances, such as methylene blue and sodium nitrite, and finally the substances containing sulphur, such as sodium thiosulphate, colloidal sulphur and cystine. Each of these groups has some advantages and some disadvantages as detoxifying agents. Thus, sodium thiosulphate is a salt of practically no toxicity, but its action is rather slow and hence of lesser efficiency in advanced intoxication. Sodium nitrite, on the other hand, has a greater toxicity but a more rapid action. By injecting sodium nitrite first and sodium thiosulphate subsequently the author obtained better results experimentally as judged by the number of animals saved than by injecting these substances separately. The effect of these antidotes was not a simple summation but a true potentiality. He proposes therefore, that ampules of amyl nitrite, a solution of 2 per cent sodium nitrite and another of 30 per cent sodium thiosulphate be kept in the satchel for emergency treatment. One patient who ingested potassium cyanide has already been treated by preliminary inhalation of amyl nitrite followed by intravenous injections of sodium nitrite and sodium thiosulphate. The result in this case was successful.

Treatment of Articular Traumatism with Procaine Hydrochloride—The treatment of sprains by intraligamentous injection of procaine hydrochloride as originally described by Leriche is extended and discussed in this report by Arnulf and Frich. The technique is simple and involves the usual skin disinfection and the injection into the painful periarticular ligamentous tissue of from 0.5 to 1 per cent solution of procaine hydrochloride, repeated if necessary, but not exceeding a total quantity of 25 or 30 cc. The rationale of the procedure lies, according to the authors, in blocking the sensory nerve endings and thus stopping abnormal excitation, obstructing the reflex and interrupting the vicious cycle in which the phenomena resulting from vasodilatation continuously renew the excitability of the periarticular sensory elements. In both recent and late traumatism examples of each of which are cited, the results of injection are more favorable and more rapid, they believe, than by the customary immobilization.

- Hepatohypophyseal Syndromes G Parturier and R Becquet—p 52

Takata-Ara Reaction—The Takata Ara reaction, according to Hugonot and Sohler, is a flocculation reaction obtained by placing the serum to be studied, diluted in convenient proportions with a freshly prepared reagent consisting of a 0.5 per cent mercuric chloride and 0.02 per cent fuchsin solution. This reaction is simple and may be practically employed in the clinical laboratory. It seems to reflect constantly any disorder of proteinemia characterized by an inversion of the serum albumin-globulin ratio and may supply or even replace the chemical tests of these albumins, which involve a complicated technique possible only in specialized laboratories. In

applying the test to a large number of cases of different types it was apparent that it was always positive in the course of disturbances accompanying profound involvement of the hepatic parenchyma or serious functional insufficiency accompanying discoverable clinical disorders of proteinemia, such as one finds in the cirrhoses. It was negative in all other diseases or dysfunctions of the liver, such as cancer, infectious hepatitis and syphilitic hepatitis. Aside from diseases of the liver, it was found positive in severe infections and in protozoal infestation of the blood (kala-azar) in which a derangement of the blood albumins is found. It does not appear that a positive reaction alone can specifically point out a hepatic lesion, but a positive reaction added to the determination of a diminution of total protein in the serum seems to be an excellent test of a severe and predominant, if not exclusive, involvement of the liver. A positive reaction in a serum having a normal elevated ratio of total proteins only translates the intensity of the humoral disorder without reference to the hepatic involvement, and often gives useful information on the course and prognosis of the disease.

Method for Measuring Blood Bilirubin—Gaydos, in attempting to prove the value of the Ernst-Forster technique of blood bilirubin estimation, made parallel tests using this method and the classic one of van den Bergh. The Ernst-Forster reaction is made in the following manner: To 1 cc of serum or plasma, 2 cc of acetone is added; this is filtered, centrifuged and the supernatant fluid compared with a standard of potassium bichromate. To prepare this standard a mother solution in the proportion of 1:6,000 in distilled water is used. This solution corresponds to a bilirubin content of 0.329 mg per hundred cubic centimeters. The comparison is made with the aid of a Duboscq apparatus or with a series of standards of graded dilutions. The figure found must be multiplied by 3 because of the dilution. If the concentration of bilirubin is low, only 1.5 cc of acetone is added to 1 cc of serum. Thus the yellow color of the filtrate becomes darker. The factor of correction in this case is 2.5. The new element in this reaction is the use of acetone for the precipitation, allowing a lower dilution. The results of the comparative studies affirmed the fact that for measuring weak bilirubinemias this reaction is superior to that of van den Bergh.

Bacteriologic Virulence During Pregnancy, Delivery and Puerperium—Koller points out that the usual bacteriologic studies during pregnancy, delivery and the puerperium have given no satisfactory explanation for the pathogenesis of puerperal infections. The frequent demonstration of streptococci and staphylococci in the genital secretions gave rise to the assumption that merely the presence of these organisms was not sufficient. The virulence of the bacteria of the genital secretion was determined, and it was found that after spontaneous deliveries the incidence of temperature increases was not higher in the cases in which the virulence of the bacteria was positive than in those in which it was negative. However, in the incidence of inflammatory, genital complications during the puerperium a difference was noted, for such complications developing in only three out of 174 spontaneous deliveries in the presence of bacteria of negative virulence, while in the presence of bacteria of positive virulence they developed in four out of thirty-six cases. In deliveries terminated by operative interventions (cesarean sections or vaginal operations), the average of the temperature increases during the puerperium is much higher in the cases in which the organisms of the genital secretions are virulent than in those with nonvirulent organisms. The incidence and severity of inflammatory, genital complications after operative interventions likewise is influenced by the virulence of the organisms of the genital secretions, for mild disturbances developed in seven out of twenty-four cases in which there were nonvirulent organisms, while thirteen out of twenty-one in which virulent organisms were

present developed inflammatory complications. Some cases in the latter group were serious and one woman died as the result of the infection. The comparison of the course of the puerperium shows that after spontaneous deliveries, even in the presence of virulent vaginal bacteria, inflammatory complications are rare and generally heal rapidly, while after operative terminations of birth in the presence of virulent vaginal bacteria such disturbances are frequent and prolonged. This is a new proof that operative interventions should be undertaken only after careful deliberation.

*Porphyrin in Pathogenesis of Pellagra U. Bassi —p 241

*Disappearance of Pulmonary Cavities After Exudative Pleurisy in Course of Artificial Pneumothorax M. Belli —p 263

Porphyrin in Pathogenesis of Pellagra—Bassi maintains that a faulty diet producing symptoms of the nervous and digestive systems is the essential etiologic factor in pellagra. The characteristic cutaneous manifestations make such an etiologic factor an essential but it is not a sufficient explanation. The action of the sun's rays or of other mechanical and thermal stimuli becomes an external physiochemical agent in the etiology of the disease. The typical pellagrous skin is pathologically sensitive to the rays of the sun. Photosensitive properties of the skin are of endogenous origin and may be identified with porphyrin. Cutaneous manifestations appear late in the development of the disease. Several patients on a faulty diet examined during the winter presented disturbances of the digestive and nervous systems but did not show any hypersensitivity to natural and artificial light. Thus the alterations of metabolism leading to an abnormal formation of photosensitive endogenous substances occur late in the pathogenesis. In patients examined during the winter, neither an increased formation nor a pathologic elimination of porphyrin was demonstrable, even after irradiations with ultraviolet rays. The function of the liver and of the kidneys was in all instances normal. These observations demonstrate the importance of the liver in pigment metabolism. A hepatic dysfunction leads to porphyrinemia together with porphyrinuria. When the disease is associated with cutaneous manifestations, the presence of porphyrin in the serum and in the urine is not always demonstrable. The absence of porphyrinuria in subjects presenting blood in the feces from small intestinal hemorrhages is new evidence against the theory of the intestinal origin of porphyrin. The increase in the porphyrin in the circulation and in the tissues might be due to increased synthesis of the porphyrins induced and maintained by the absence of vitamins in a faulty diet.

Disappearance of Pulmonary Cavities After Exudative Pleurisy in Course of Artificial Pneumothorax—Belli observed the beneficial influence of a pneumothorax pleurisy on tuberculous pulmonary cavities in seven patients in whom pneumothorax was not effective and after exudative pleurisy occurred. In considering the duration of the pneumothorax of the same type at the time in which the parenchymal alterations took place he maintains that there is a relation of cause and effect between the exudative pleurisy and the facts observed. Roentgenologic, clinical and bacteriologic studies impel the author to advance the hypothesis there had been a true and actual cure of the tuberculous cavities corresponding to the disappearance indicated by roentgenologic means. He emphasizes how difficult it is to confirm such a cure with certainty during a lifetime. These difficulties are increased in the described cases by the absence of observations on re-expanded lungs. In all cases a subjective and objective improvement was demonstrated in addition to the disappearance of the tubercle bacilli from the sputum. The author discusses the various theories regarding the mechanism of the beneficial influence of exudative pleurisy on parenchymal lesions. Following the ideas expressed by Tendeloo concerning the mechanism of pneumothorax he is inclined to attribute to exudative pleurisy a complex of mechanical and immunizing factors

favoring histogenous immunity. The author states in conclusion that the therapeutic utilization of these effusions may offer marked benefits that the pneumothorax alone could not produce.

Painful Abdominal Aorta in Abdominal Sympathosis—Gonzalez Bosch says that the coexistence of an extreme, painful sensitiveness of the abdominal aorta and the iliac arteries, when these structures are pressed against the vertebral plane, with an abdominal syndrome characterized by painful crises, generally with epigastric localization and with the characteristics of celiac neuralgia, serves as the basis of the diagnosis of abdominal sympathosis (Taddei's abdominal sympathosis). This syndrome is caused by a defective function of the abdominal sympathetic, caused by various local and general factors of constitutional, toxic, mechanical and inflammatory nature.

Injuries of Crucial Ligaments of Knee—Felsenreich states that, as the result of the enormous increase in sporting activities, injuries to the crucial ligaments of the knee joint became a frequent and typical lesion. These lesions are rather frequently overlooked in the course of arthrotomies. Immediate examination after the injury, examination after aspiration of hemarthrosis and of the anesthetized joint are of value in the diagnosis of acute cases. "Locking action" of the joint, abnormal adduction with the limb at 160 degrees and a positive roentgenogram constitute the cardinal symptoms. The "locking action sign" (forward or backward dislocation of the tibial head) is not present if the tibial spine is completely torn off or if a torn meniscus is interposed between the condyles. It is likewise absent in the presence of a large effusion in the knee or swelling of the capsule. A positive diagnosis can be made immediately after the accident before the swelling of the joint takes place and before the lesions pass into a chronic state. In the interim the diagnosis can be arrived at through repeated examinations, especially after aspiration of the knee or with the aid of local anesthesia of the knee. Inconstancy of the symptom of locking of the knee, an active "locking" sign and occasionally a snapping knee are suggestive of a chronic lesion of the crucial ligaments. The roentgenographic observations are positive in a higher percentage of such cases than in the recent ones. The aim of treatment is the restoration of the active and passive stability of the joint. In the recent cases the treatment is preeminently conservative except when the tibial spine is completely torn off or in the presence of a locked meniscus that cannot be reduced. In the after-treatment, active exercises are important. Recurrence of the locking of the knee is an indication for an operation of the conservative type, such as the removal of a fractured meniscus (loose body) or smoothing out of the interior of the joint. If the conservative procedure fails and there is loss of working capacity or capacity for sports, and if the patient requests it, the surgeon should resort to the operation of forming new ligaments from pedicled fascial transplants. The results of this procedure as gleaned from the literature and personal experience are quite good.

Fat Embolism—Susani states that fat embolism is caused by neutral fat, principally triolein. For this reason, determinations of the total lipids or of partial lipids are of no diagnostic value. The normal neutral fat values as given in the literature are frequently grossly erroneous. The author presents exact methods for the determination of the presence and the amount of neutral fat and proposes a definite procedure. Increase in the neutral fat in the peripheral blood may be demonstrated in severe fractures complicated by shock. The author considers this increase a manifestation of latent fat embolism. There exists an alimentary hyperlipennia which is several times that of a normal starving state. The fatal amount of fat is dependent on the state of division of the fat. In a moderately coarse state of division portions of the amount, which in the undivided state causes death, may have a fatal effect. Unbroken fat leads to cardiac death, while emulsified fat leads to death by suffocation. Conclusions as to the value of drugs in fat embolism caused by neutral fat, based on determination of lipids, are not reliable. Estimation of neutral fat in patients with possible fat embolism assists in the diagnosis and suggests the correct therapeutic procedure.

*New Method of Anterolateral Thoracoplasty W. Leimer—p. 505

Influenza and Pulmonary Tuberculosis—Mandel relates his observations in the course of an influenza epidemic in a sanatorium for tuberculous patients. The epidemic was comparatively mild, since of the 104 patients none developed complications. He is convinced that in different influenza epidemics the course of the infection as well as the complications show a certain variability. He thinks that this may explain the difference in opinions about the effect of influenza on tuberculosis. In his own material, 11.25 per cent of the tuberculous patients developed considerable exacerbations, aside from mild impairments detectable only by laboratory methods. He therefore concludes that patients with tuberculosis should be protected against influenza as much as possible. If in spite of all precautions a tuberculous patient develops influenza he should be carefully watched during and after the attack, so that an exacerbation will be discovered immediately and proper therapeutic measures may be taken. The influenza-like disturbances developing after epidemics should be given particular attention, since they frequently mask a tuberculous relapse or an early infiltrate. Hematologic studies are helpful for the differential diagnosis, because the quantitative and qualitative hemogram as well as the sedimentation speed of influenza differ from those of tuberculosis.

Method of Anterolateral Thoracoplasty—Leimer describes a new method of thoracoplasty, which was developed by Monaldi. The operation differs from other plastic operations on the thorax in that its aim is not bony fixation of the collapse but rather exclusion of the respiratory movements that injure the lung. For this reason union of the bones is intentionally prevented. By thoracographic studies, Monaldi found the line of greatest movement of the thorax, which is practically the same in all persons. If it is the aim of the operation to exclude all forces the changes of which disturb the resting position of the lung, it has to accomplish paralysis of the diaphragm, exclusion of the traction of the scaleni muscles with resection of the first rib, and resection of the upper ribs along the line of greatest movement. Then the lung can collapse and rest against the posterior thoracic wall and the mediastinum, which do not participate to a great extent in the respiratory movements. The newly produced physiologic condition is characterized by the paradoxical respiratory movement and since this condition is supposed to be permanent, a reunion of the ribs is prevented by destruction of the periosteum. The operation is performed under local anesthesia and in two stages. During the first session the ribs from the fourth

to the eighth are resected, the incision being slightly curved or horizontal. During the second session the first four ribs are resected, the incision is made underneath the clavicle, then parasternal and in a curve downward. The resection is made along the line of greatest movement. The first rib is almost completely resected. The second, third and fourth ribs are resected from the cartilage to the median axillary line. Beginning with the fifth rib, the length of the resected portions decreases, it being from 5 to 10 cm. The periosteum is destroyed by solution of formaldehyde. In order to reduce the operative shock, especial attention is given to the preservation of the muscles. Paralysis of the phrenic nerve is obtained by crushing rather than by avulsion.

Neuritis in Persons Transplanting Beets—Kroll calls attention to a paralysis of the muscles of the leg which develops in persons who transplant beets. The work requires a squatting position and observers agree that the disorder is the result of pressure and dragging on the nerves of the leg to which is added overexertion and, according to the author, also a rheumatic factor, namely the dampness of the ground. The patients complain of formication and of the member going to sleep. Paralysis and severe pains follow. In the seven patients observed by the author the right leg was always more severely affected and he thinks that in persons working with the right hand an involvement of the right leg is more likely. In most cases the peroneal and tibial nerves were impaired and this resulted in a paralysis of all the muscles of the lower part of the leg, in manifestations of partial or total degeneration and in atrophies of moderate severity. The sensitivity disturbances were only partial in extent and intensity. The femoral nerve was involved in two instances and there was an increase or a decrease of the right or of both patellar reflexes in all except one of the patients. The achilles tendon reflexes likewise were changed. The prognosis of this form of neuritis seems to be favorable at least as far as recovery is concerned, but the course of the healing process is rather slow. The author recommends heat therapy in the form of light cabinets, ultrashort waves or galvanization. Protein therapy seems to be helpful. In order to prevent paralysis the workers should be instructed to quit this type of work as soon as formication sets in.

Blood Pressure Crises and Tumor of Suprarenal Medulla—Kalk gives the history of a patient with a tumor of the suprarenal medulla which was successfully removed. In this case the blood pressure was not constantly increased. The hypertension occurred in attacks and the symptoms were limited to those traceable to the suprarenal medulla, the other excretory functions, with the exception of those of the parathyroids, being normal. The counter regulation with sudden decrease in blood pressure, redness of the face, contraction of the pupils, profuse sweating and salivation which occurred at the height of the attacks, seemed to indicate the sudden elimination of a hormone antagonist of epinephrine. The author points out that cases of this nature may be more frequent than

is generally thought and he thinks that perhaps cases of proxymal hypertension are due to tumors of this type. Moreover, it is possible that the so-called blood pressure crises (Pal) are often due to tumors, or at least to a hyperfunction of the suprarenal medulla.

New Phenomenon in Disturbance of Arterial Blood Supply—Feil and Wermer point out that in patients with endarteritis obliterans or arteriosclerosis of the vessels of the lower extremities with intermittent claudication the following phenomenon may be observed. When the patient bends the leg at the knee joint while lying face down or lifts the leg while lying on his back, the sole of the foot becomes pale within from thirty to ninety seconds and frequently paresthesias develop. The authors found this phenomenon of no particular value in the generally doubtful prognosis of endarteritis obliterans and beginning arteriosclerotic gangrene. However they made a further observation which they consider significant. In a patient with thrombo angitis obliterans and intermittent claudication in the left leg the lifting of the diseased member produced the pallor within thirty seconds but after another thirty or 120 seconds the pallor was followed by a light red coloration which first appeared in an area the size of a small coin and by the development of further spots gradually spread over the entire sole of the foot. The color was light red, not at all cyanotic, it differed noticeably from the color of the foot before it became pale. The authors watched for this phenomenon in other cases and observed that it appeared in eight out of ten cases of intermittent claudication in which the pallor was noted. The authors express the opinion that the presence of still dilatable vessels is a prerequisite for its development. On the basis of this phenomenon the cases of intermittent claudication can be divided into three groups: 1. The mild cases in which lifting of the member causes no changes. 2. The cases of medium severity in which pallor and subsequent hyperemia develop. 3. The severe cases in which pallor only develops.

Hoof and Mouth Disease—Von Scheitz states that human subjects are most readily infected by raw milk. Another mode of infection is contact with a diseased animal. Transmission from man to man is still somewhat doubtful. The incubation period is fairly short in human subjects, lasting as a rule two or three days. This is followed by the primary blisters and high fever with general debility. In the second phase the secondary blisters and aphthae develop. This phase may assume widely different aspects. In typical cases grayish white aphthae about the size of a pinhead or blisters of the same size appear on the buccal mucous membrane, tongue and gums. The mucous membrane is swollen and painful and salivation occurs. The food intake is difficult. The vesicles may appear on the fingers and toes, aphthae may develop on the nostrils and lips and the conjunctiva may become inflamed. The vesicles and aphthae burst after one or two days and the temperature decreases. The secondary symptoms may take the form of an inflammation of the nails and cutaneous eruptions may appear on any part of the body producing a generalized maculopapulous exanthem which may become hemorrhagic. In many instances the secondary symptoms are rather mild and hardly noticeable. For this reason the diagnosis must be based mainly on the primary blisters and the typical fever curve. The most frequent complication of hoof and mouth disease is an involvement of the cardiac muscle. The disorder has been mistaken for milkers' nodules, erythema exudativum, multiforme and herpes. The author gives a history of one case which showed the typical double phase and the beneficial effect of intravenous injection of neosphenamine. Electrocardiography revealed a temporary involvement of the cardiac muscle. Vaccination of guinea pigs with extract of the aphthae gave positive results and passage likewise was accomplished. One investigator vaccinated himself with a highly virulent strain four months after an infection and he did not contract the disease again. The author stresses the beneficial effects of neosphenamine. He also found that the application of nupercaine ointment counteracts the pain of the mucous membrane for six or seven hours. Irrigations with a 2 per cent boric acid solution or with camomile tea are helpful in the treatment of the oral symptoms.

Alcohol Injections in Diseases of Lungs—Intravenous alcohol therapy first introduced in 1928 by Thursz for malignant tumors and puerperal sepsis and later found helpful by Landau and his associates in the treatment of pulmonary complications was employed successfully by Brüll in various pulmonary disorders, such as abscess, gangrene, lobar pneumonia, bronchopneumonia and bronchiectasis. He administered the 15 per cent alcohol solution in distilled water in doses of 20, 25, 30, 35 or 50 cc. The highest dose was 80 cc. In contradistinction to the more concentrated alcohol solutions, the 15 per cent solution proved entirely harmless and was well tolerated by the vein. As the result of this injection treatment eight patients with acute solitary pulmonary abscesses and gangrene recovered without operation. In cases presenting complications in neighboring organs, or severe diabetes, the alcohol therapy was unsuccessful but temporary improvements were noted in some of these patients. The alcohol injections produced a considerable improvement in three out of eight patients with bronchiectasis; in two patients the effects were slight, while in the other three the treatment was entirely ineffective. Six out of eight patients with bronchopneumonia were greatly improved by the alcohol injections. In five cases of lobar pneumonia the alcohol injections exerted a favorable effect but did not shorten the course of the disease. Patients with pleural empyema were treated with intrapleural injections of the 15 per cent alcohol solution. The treatment was well tolerated and the results obtained thus far justify further trials. In pulmonary tuberculosis, the alcohol injections were ineffective.

Prevention of Postoperative Tetany—Grasmann says that the upper parathyroids are usually found at the level of the cricoid cartilage on the median edge of the thyroid close to the lateral wall of the esophagus. His assumption that especial attention given to the preservation of the upper parathyroids would reduce postoperative tetany has been verified. The necessity of preserving the upper pole of the thyroid which was recommended by de Quervain is not yet commonly known by surgeons. The author considers the preservation of the posterior branch of the superior thyroid artery the most reliable measure against the impairment of the upper parathyroids for when the trunk of the superior thyroid artery is ligated and severed there is great danger that the upper pole of the thyroid is removed too far and that the upper parathyroids are injured. He always preserves the entire posterior wall of the upper pole to a thickness of several millimeters.

Mediastinal Emphysema and Pneumothorax in Goiter Operations—Keis relates the history of a woman aged 32 who died following an operation for recurring goiter. The postmortem examination revealed mediastinal emphysema and bilateral pneumothorax. The author thinks that the position, size and adhesions of a substernal struma play a part in the

pathogenesis of mediastinal emphysema, but, since it develops also in suprasternal strumas, there must be other factors. In young persons, the mediastinal connective tissue is loose and the mediastinal pleurae are delicate and movable. The complete or partial retrogression of the thymus creates spatial differences, which in adults may be constitutionally increased by the presence of a long and narrow or a short and wide thorax. The changes that may be caused by pathologic processes in the organs embedded in the mediastinum should not be overlooked. The reaction sensitivity of the mediastinum is great and it is influenced by the comparatively frequent inflammatory conditions of the trachea and of the lymphatic apparatus. Such inflammatory reactions may lead to a rigidity of the mediastinal connective tissue and of the mediastinal pleurae, which in turn reduces the suction capacity of the mediastinum. In some of the cases of mediastinal emphysema a bilateral pneumothorax develops, although a pleural injury is not demonstrable. To determine the mechanism of the entrance of air into the thorax, mediastinal inflations were made on cadavers. The author points out that on living subjects the requirements for the loosening of the mediastinal pleurae are still more favorable. The respiratory movements have a massage-like effect on the mediastinum and press the air into the connective tissue interstices. The intrathoracic suction during inspiration lifts the pleura that rests loosely on the pericardium and thus facilitates the entrance of air. During expiration the air is pressed further. Since the vesicles permit an escape of air in case of a medium inflation of the mediastinum the assumption is justified that the negative thoracic pressure during inspiration sucks air from them and that during expiration air is forced out. Thus depending on the degree of mediastinal pressure, all degrees of pneumothorax may develop, if the mediastinum is not released in due time. Since the changes in mediastinal emphysema are nearly always bilateral, the fact that the pneumothorax is also generally bilateral is understandable. That mediastinal emphysema does not develop in pneumothorax is due to the fact that the mediastinal pleurae are pressed to their substratum.

Treatment of Congenital Umbilical Hernias—Friedrich emphasizes the necessity of an early radical operation for cases of congenital umbilical hernia (eventration). The operation should be done immediately after birth or at least within the first six hours. The early intervention produces excellent results. Even in cases of extensive eventrations, provided no other serious complications are present, the nurslings usually can be saved. The author advises the use of local anesthesia with an addition of epinephrine. He gives a short description of a simplified surgical method, which he employed successfully in four cases. He considers suturing in three layers difficult and inadvisable and recommends a single suture. Small children tolerate an operation better than adults. He is convinced that the former unfavorable results and high mortality rates in operations for eventration were largely due to the fact that the intervention was made too late.

*Fat Content of Fecal Matter After Gastro Enterostomy I Snapper
—p 361

Epidemiology of Malaria in Dutch Guiana F M Peter —p 370

Fat Content of Feces After Gastro-Enterostomy—Snapper found that after gastro-enterostomy the fat content of the feces generally increases. He states that this is due to an excessively rapid passage of the chyme through the jejunum as a result of the operation so that there is too little time left for the resorption of the fat. In some patients this chronic loss of fat in the feces seems to be the cause of emaciation and fatigue. Exceptionally it may be necessary in these cases to undo the gastro enterostomy. If however true fatty feces and fatty diarrhea occur after gastro-enterostomy there is always a gastrojejunal fistula. A peptic ulcer which often develops in the jejunum after gastro enterostomy can cause

adhesions to the colon. As a result there is a communication between the jejunum and colon and consequently an open connection between the stomach, jejunum and colon. The characteristic symptomatology of the condition includes fat diarrhea, eructation of fecal matter and roentgenologic filling of jejunum and stomach after administration of a barium enema. The author describes three patients presenting the characteristic symptoms of gastrojejunal fistula, one of whom showed symptoms of tetany. Operation of the gastrojejunal fistula in all cases gave immediate disappearance of fat from the feces, and the general condition of the patients improved rapidly. One patient developed new duodenal ulcers after the fistula had been closed. Several operations took place after this, the last terminating in death.

Quantitative Studies of Bone Marrow N G Nordensson —p 193

Studies of Bone Marrow—Nordensson made about 170 punctures of the sternum employing the technic described by Arinkin. In normal bone marrow he found between 0.25 and 5.5 per cent myeloblasts, the sum of the myelocytes and the promyelocytes varied between 2 and 21.75 per cent, and the sum of the cells with rod-shaped nuclei and with young nuclei between 3 and 47 per cent, as a rule exceeding the sum of the myelocytes and the promyelocytes. In 400 white cells the number of megakaryocytes was never more than one, the number of reticulocytes averaged seventeen and there were from none to four pronormoblasts, with an average of six basophilic normoblasts and seventy normoblasts. In secondary anemia with and without leukocytosis and with leukopenia the number of the myeloblasts was about normal, the sum of the promyelocytes and the myelocytes varied from 16 to 40.25 per cent being usually above normal, and the sum of cells with rod-shaped nuclei and with young nuclei varied from 11.75 to 41.25. There were thirty-five basophilic normoblasts for 400 white cells, as against six normally. The relation between basophilic normoblasts and those containing hemoglobin was 1:2, while in normal bone marrow it is 1:12. In leukocytosis and leukopenia without secondary anemia the percentage of increase of myelocytes and promyelocytes was in most cases more marked than in secondary anemia. Pernicious anemia in the "full stage" was characterized by a general activity of the myelopoietic and erythropoietic systems. The myeloblasts were increased, the sum of myelocytes and promyelocytes rose to between 20 and 46.25 per cent, and the sum of cells with rod-shaped nuclei and with young nuclei sank to between 0.25 and 10.5 per cent. The cell groups which normally dominate the bone marrow were thus reduced to a minority and the promyelocytes and myelocytes, together with the myeloblasts, dominated the white cell picture of the bone marrow. The change in the other cells was perhaps even more marked. Most of the cells in the bone marrow in pernicious anemia showed signs of degeneration. On treatment with liver the megaloblastosis lasted about twelve days before transition to definite normoblastosis. During remission the bone marrow lost its degenerated appearance and the cells regained their normal configuration. In a case of agranulocytosis the sternal marrow was almost empty, and in two cases of granulopenia the cells were remarkably abundant and showed considerable activity. The erythropoiesis was of the type seen in secondary anemia. In three cases of lymphogranulomatosis the sternal punctate was deficient in cells, especially in the two cases undergoing roentgen treatment, in which the marrow was inactive. In the third case in which the last roentgen treatment occurred two months earlier the marrow was not inactive. Cells of the erythrocyte series were few with relative preponderance of basophilic normoblasts. In one case of acute and one of chronic lymphatic leukemia particularly in the former the punctate was deficient in cells. The myelopoietic and erythropoietic systems were practically destroyed.

CORRECTION

Hemisection of Cochlear Branch of Auditory Nerve—In the abstract in THE JOURNAL of Dr. Walter E. Dandy's article May 26, page 1806, in the third line the words "sensory root of the fifth nerve" should have been "cochlear branch of the auditory nerve."

EXTENSION POSTGRADUATE MEDICAL INSTRUCTION IN THE UNITED STATES AND CANADA

LEROY E PARKINS MD

Secretary to the Harvard Medical School Courses for Graduates
BOSTON

The amount of useful information of the medical profession has increased from generation to generation, especially in the last fifty years. The members of the medical profession are guardians of this great fund of knowledge, which should be used to its fullest extent for the good of mankind. The dissemination of this knowledge and its actual application to the relief and prevention of suffering constitute a continuous problem. Improvements in treatment and new discoveries are constantly being made, so that it is necessary for all physicians to continue to study if they hope to fulfil their trust and give the best possible medical service.

The store of professional knowledge is in the medical schools, the health departments, the medical libraries and hospitals, and the minds of highly educated physicians. The agents for disseminating this information so that it may become an actual force in improving the community health are the organized medical schools, undergraduate and graduate, organized medical societies of all types, postgraduate extension schools run by universities, medical societies or departments of public health, medical books, and professional journals. If all these methods of providing instruction were at the highest point of efficiency and interest in them were 100 per cent, the practice of medicine would be materially improved.

The quality of these various agents has improved especially since the beginning of this century. From 1899 to 1905 THE JOURNAL¹ pioneered in classifying medical schools on the basis of each school's own statement of its ability to teach medicine, this haphazard method soon gave way to inspection and classification of schools on the basis of their actual assets, which were often not what they were advertised to be in their well printed catalogues. Also, it was in 1910 that the Carnegie Foundation published its independent survey of medical schools with its candid and sometimes scathing criticism of poor teaching facilities. The combined result of this has been especially to improve teaching in the undergraduate field. The Council on Medical Education of the American Medical Association has annually issued a register of medical schools and classifies them according to definite standards of equipment,

clinical facilities and faculties. The work of this body has been a continuous influence for good in advancing the standards of medical practice.

Postgraduate teaching facilities have not improved as rapidly as in the undergraduate realm. In fact, at the present time postgraduate medicine is essentially a proprietary field, as only one school has any appreciable endowment (Albany Medical College has \$250,000 endowment) for strictly postgraduate teaching. This may be due to two reasons. First, no great effort has been made to improve this situation comparable to that made for undergraduate medicine. Second, the profession itself has not demanded very much teaching—not enough to justify expansion of faculty or facilities. The Final Report of the Commission on Medical Education in the United States (1932, p 128) states that each year approximately 3,500 doctors take resident postgraduate courses in this country and about 1,000 go abroad for similar work, besides this there are 2,144 doctors in residence in 372 hospitals. This makes a grand total of 6,644, or 4.2 per cent, out of the 156,440 MD's in the United States who consider it desirable and feasible to continue their studies in a systematic manner away from their practice.

There is no doubt that some physicians keep abreast of advances in medicine by observation and home study, but for the majority some outside stimulus is useful and often necessary. The bookmaking art has reached a high plane and medical journals are legion, however, the interested and interesting teacher is still the mainstay of the educational system. In all ages teachers have exercised a leavening influence in their communities, and often a very large portion of the world might be called their field. Information and inspiration have greater effect when given by personal contact, the convincing voice of an experienced clinician carries more conviction and conditions medical reflexes for good more effectively than any printed page.

The outstanding phenomenon in the graduate field of medical education is the rapid growth of extension teaching in both the United States and Canada since 1916 at which time it was first initiated by the state of North Carolina at the suggestion of Dr W S Rankin, public health officer of that state.² The idea of bringing medical knowledge to the community so that every doctor can know the latest and best in his profession by contact with teachers has been put into effect in twenty-two states and all of the provinces of Canada. This is a partial answer to the question of why more doctors do not go away to postgraduate schools. In this area there are approximately 120,332³ MD's who, one might say, have been exposed to organized postgraduate study opportunities. Often, and particu-

³ American Medical Directory ed 12 Chicago American Medical Association 1931.

larly in these times, a doctor cannot afford to leave his practice to go to postgraduate teaching centers. In some smaller villages there is only one physician, and he may hesitate to leave the community without medical care in time of unexpected emergency. The important fact is that the profession as a whole has expressed interest in and a desire for continued organized study. This great need presents an opportunity to medical school faculties and all leaders of the profession. Teachers are needed to "carry the message to Garcia."

In all these fields of medical education there is no competition and there are no cross purposes. The undergraduate days are a period of probation. Following this the doctor enters the postgraduate era of his career—a lifelong session, if he is to achieve his best and have the highest satisfaction in his work. Society has become interested in postgraduate careers and has made laws that require a year of internship service before granting a license to practice in the following states and territory: Delaware, District of Columbia, Illinois, Iowa, Michigan, New Jersey, North Dakota, Oklahoma, Oregon, Pennsylvania, Rhode Island, South Dakota, Utah, Washington, West Virginia, Wisconsin, Wyoming and Alaska. This is essentially continued study while applying one's knowledge. The American Medical Association and the American College of Surgeons grade the hospitals, thus the hospital staff members are approved teachers. The Massachusetts General Hospital calls its interns "house pupils," which is an old term but it reflects the true situation of the young doctor. It is the duty of the profession to observe and study unceasingly by means of books, medical journals and active participation in organized study or teaching. Education in a democracy means a sharing of knowledge as well as a sharing of the benefits of material civilization.

All these modes of continued medical education mean an enlightened profession and consequently better medical service. This has great significance in private practice as well as in the field of public health, where success depends to a great extent on the intelligent cooperation of the practicing physician. Increasing the fund of useful knowledge and applying it should improve the economic status of the profession, and, what is more important, it should enable physicians more nearly to fill their proper place as leaders in the art of healing. No longer should any remote geographic region suffer from neglect, the fruit of ignorance. Transportation has transformed distance, and study will banish the frontiers of ignorance.

The ability of doctors varies in different communities. As physicians we know this, and that laymen recognize it too is shown when they travel across a state or beyond its borders to seek relief by some physician in a well known clinic. It is interesting to speculate what is the essential difference between the doctors in a community and those in a well recognized clinic. Is it not largely in their attitude toward study and the actual use of new knowledge in giving intelligent service to patients? The personal equation of 1,000 doctors anywhere in the land will compare favorably with a like number of professional brothers elsewhere. Material things, such as laboratories, x-ray machines and instruments of precision are of secondary importance, they are mobile paraphernalia which can be moved anywhere and are only adjuncts to the use of knowledge. The well educated physician makes proper use of all knowledge related to the welfare of the patient and his community.

While assisting the Massachusetts Medical Society to organize a system of extension teaching during the past year, I have had occasion to investigate similar work elsewhere. A summary of this study is presented as evidence of the widespread interest in postgraduate education among the profession. No body of professional workers will devote more thought and energy to accomplishing ends when a worthy goal is set. It is reasonable to believe that this growth of extension teaching marks the dawn of a new era in postgraduate medical education. This interest is reflected in changes and new ideas in intramural teaching as well. This expansion of interest in acquiring new knowledge is part of a world-wide renaissance in adult education which is permeating all phases of life.

MEDICAL EXTENSION TEACHING

The following summary of medical extension teaching in the United States and Canada gives data that may be of interest to states in which such work is not done, also, it provides a means of comparing the costs of such work. The best method of organization has not been worked out as yet, but in these states there is an active interest which augurs well for the future training of the profession.

Canada—Extramural postgraduate medical education in Canada has been in progress since 1926. The lectures are open to every doctor whether or not he is a member of the Canadian Medical Association. It is estimated that a majority of the 10,000 doctors in Canada have at some time enjoyed these meetings. There is no charge for lectures. The instructors for the most part have been university teachers. Expenses have been paid as well as an honorarium of \$10 a day for the time the instructor is away from home. This work was made possible during the years 1926 to 1932, inclusive by an annual grant of \$30,000 from the Sun Life Assurance Company of Canada. All details of organization have been handled by the central office of the Canadian Medical Association. Speakers are sent to meetings of organized medical societies which are responsible for local arrangements, the instructors go out in teams of two, if sent to distant provinces, a series of meetings is arranged en route in order to save expenses. Figures for 1926-1932: number of speakers, 2,156; number of addresses, 4,889; average attendance 329; total attendance 161,210; total cost \$212,847.52; cost per lecture, \$132 per doctor. Members have been enthusiastic about the lectures and have traveled from 50 to 150 miles to attend. Canada is the only country in which postgraduate medical education has been handled on a national scale. The grant from the Sun Life Assurance Company has been temporarily withdrawn, owing to the business depression.⁴

Colorado—During 1924 clinics were given by ten teams of four doctors each, who visited a locality once each month for six months. No team visited the same locality a second time and all teams represented, as far as possible the same four specialties. The faculty paid their own expenses.

For several years previous to 1927, Colorado held an annual state clinic. This was given at the University of Colorado Medical School and consisted of four days of intensive work covering all phases of medical study. The average attendance was about 300. A traveling clinic of four days' duration was held at irregular intervals in which the extension division of the University of Colorado the medical school the Colorado Agricultural College the state tuberculosis association and the child welfare bureau participated. For these traveling clinics the teams were made up of a pediatrician, a psychiatrist and an obstetrician chosen either from the faculty of the medical school or from among the leading practitioners of the state. Expenses were met by the participating organizations.⁵

In January 1933 the state medical society sponsored for the first time a three-day postgraduate clinic series (diagnostic and

⁴ Dr. T. C. Routley, general secretary, Canadian Medical Association, personal communication to the author, March 3, 1933.

⁵ American Medical Association Bulletin 22, June 1927.

therapeutic only), which was given independently but with the cooperation of the medical school. No salaries were paid instructors. More than 200 physicians registered out of a state society membership of 1,114.⁶

Connecticut—The state medical society, with the cooperation of the Yale University School of Medicine, initiated a clinical congress of three days' duration in 1924. Until 1929 the registration fee was \$10, at which time there was a surplus of approximately \$3,000, the average attendance having numbered 325 doctors out of a state society membership of 1,396.⁷ In 1929 the fee was reduced to \$5, a charge sufficient to cover all expenses provided the enrolment totaled 275 doctors. This three-day congress includes morning sessions devoted to the didactic presentation of subjects, afternoon sessions devoted to round table discussions, and two evening meetings devoted to the social and economic problems of medicine. The fee for the congress includes the cost of circularizing with preliminary programs, luncheons and the expenses of visiting speakers (which are defrayed). This is considered a successful venture. This is not the extension method of instruction but represents the organized effort of this medical society to provide postgraduate instruction for its membership.

Florida—Postgraduate courses were inaugurated June 19, 1933, by the Florida Medical Association in connection with the Extension Department of the University of Florida. Instructors receive traveling expenses and maintenance while in Gainesville.⁸

Georgia—Extension courses were first started in 1918, special emphasis was centered on the diagnosis and treatment of syphilis in seventy-two health unit clinics of rural counties, also a clinic week was held in Atlanta which was attended by 142 physicians from eighty-four counties. In 1931 the total registration for the clinic week was 3,062 and attendance was counted as postgraduate work. As a direct result a reduction of 40 per cent of brain syphilis in the state hospitals has been noted since 1919. The University of Georgia Medical Department organized an extension course through the county medical societies holding one-day sessions. Later five-day courses were established.⁹

Extension courses are now given with the cooperation of the state medical association, the medical society of the county in which the course is held, the state department of public health, the University of Georgia Medical Department and Emory University School of Medicine. The faculty is drawn half and half from the two medical schools and the professors are paid only expenses. No charge is made to the doctors attending the course, local expenses are borne by the county medical society, correspondence and other expenses are borne by the state department of public health.¹⁰

Illinois—A scientific service committee was established by the state medical society in 1923 to carry postgraduate extension teaching service to the county medical societies. One of its most popular methods of doing this has been by means of teams of from four to six members of the faculty of one of the medical schools. The society frequently sponsors a clinicopathologic conference (internist, surgeon, pathologist). In September 1933 a series of pediatric meetings was held throughout the state by teams of six, one member of each team being outstanding in this specialty. County societies are privileged to select a subject and request an all-day meeting, to meet these requests nearly 400 physicians are listed in the state medical society's speakers bureau with the subjects they prefer to present to any county medical society. In 1932 speakers were sent to more than 150 medical society meetings in Illinois.¹¹

Indiana—Indiana University School of Medicine has given, for a number of years, occasional postgraduate work for the various county medical societies. Feeling that this did not fill

the need, the state medical association held a successful two-day meeting in Indianapolis in the summer of 1932. The registration fee was \$2.50, speakers from within the state received no remuneration, speakers from without received their traveling expenses. The association held a one-day program at Richmond in the summer of 1933. The Indiana University School of Medicine gave a two-week postgraduate course in Indianapolis in 1933.¹²

Iowa—The speaker's bureau committee of the state medical society inaugurated postgraduate work in 1929. The State University of Iowa College of Medicine outlines the courses and furnishes the lecturers, the bureau manages them. In 1929 two courses, obstetrics and pediatrics, were given at Waterloo (forty-three registered) and Mason City (forty registered). Meetings were held from 5 to 10 p. m., one day a week for a period of ten weeks, the fee was \$10. Only the expenses of the lecturers were paid. In 1930, courses were given in five centers, a course in cardiovascular diseases was added and the fee was increased to \$20. In 1931, courses were given in five more centers, a course in surgery was added and the fee remained unchanged. The demand for these extension courses was too great for the college of medicine to handle so the state medical society began to run them independently. In 1933 the association conducted three such courses, the fee was \$10. Instructors were drawn from the State University of Iowa College of Medicine and from other prominent doctors in the state as well as doctors from outside the state.¹³

Kentucky—For several years a two-week course of graduate instruction has been given at the University of Louisville School of Medicine, for which there is a registration fee of \$2. Weekly postgraduate extension courses in obstetrics, in cooperation with the state board of health, have been given since 1931. No registration fee is charged, and the expenses of instructors are paid by the state board of health. Dr. P. F. Barbour, president of the state medical association, arranged for a series of courses for county medical societies in 1933. Societies were to be supplied with two men each day for one week, the entire day to be spent in demonstrations and dry clinics, the association was paying the expenses of the teams so that there would be no local charge.¹⁴

Massachusetts—Postgraduate instruction was begun by the Massachusetts Medical Society in September 1933. There are eighteen district societies that are 100 per cent organized, and instruction is now given in twenty-four centers. The program is supervised by a committee of eighteen representative doctors chosen to correlate all the medical teaching interests of the state, this committee appoints an executive committee of three and a secretary to handle the details of organization. A registration fee of \$5, plus an appropriation of \$1,000 by the society, will meet the expenses of this first year. A faculty of 174 doctors will give 240 sessions of two hours each this year, instructors go to the districts in teams of two or three members. The course is now (February 1934) in progress, 1,002 doctors are enrolled out of the society membership of 4,797. A more detailed report of methods and results will be published later.

Michigan—For about ten years (1927 statement) organized teams have gone to the county societies for an afternoon and evening program. Also they have held district conferences similar to the Ohio plan (thirty in fourteen districts during 1926) and postgraduate clinics at the leading hospitals of the state. November 1926, 300 attended the University of Michigan Hospital.¹⁵

The state medical society, under the direction of the University of Michigan Medical School, gives in Detroit postgraduate extension teaching of a formal and continuous character. Instruction is given almost entirely by men from the local profession; payment to instructors is made at the rate of \$10 per teaching hour. These men receive \$20 per teaching hour if lecturing at the university.

11 Dr. Harold M. Camp, Illinois State Medical Society, personal communication to the author, Sept 29, 1933.

12 Thomas A. Hendricks, executive secretary, Indiana State Medical Association, personal communication to the author, March 23, 1933.

13 D. M. Nelson, secretary, Speaker's Bureau Committee, Iowa State Medical Society, personal communication to the author, April 5, 1933.

14 A. T. McCormack, secretary, Kentucky State Medical Association, personal communication to the author, March 25, 1933.

The medical school and state society, in conjunction with the Children's Fund of Michigan, have set up an auxiliary to the University Hospital at Marquette, where a year-round program in the teaching of pediatrics is conducted. About six subcenters have been established where teaching clinics are held at more or less regular intervals by the director of the central unit. (In the first fifteen months this unit cared for some 2 500 children)

Since about 1923, postgraduate clinical conferences of from one to three days have been given in the fifteen congressional districts of the state from one to three times a year. If within 100 miles only expenses of instructors are paid, if a greater distance is traveled \$25 is added for each day or part of a day occupied. Attendance has averaged about 3,000 in the course of a year.¹⁵

Minnesota—A committee appointed by the state medical society (known as the State Committee on Medical Education and Hospitals), cooperating with one appointed by the medical school, determines who shall be in charge of lectures and demonstrations in the various fields and specialties of medicine. In conjunction with the extension division of the university, this committee publishes and distributes to all county societies a booklet containing information relative to the courses and lectures that are available. No salaries are paid. The local county societies guarantee expenses for lecturers together with a nominal fee to cover the cost of printing, postage and the like.¹⁶

Missouri—The state medical association has a committee on postgraduate courses which provides the various county medical societies with speakers. Expenses of the speakers are paid by the association.¹⁷

New Hampshire—In 1932 extension teaching in the form of an obstetric institute was conducted in each of the several counties by a full time instructor. This institute was sponsored by the state board of health, with the cooperation of the county medical societies. Tuition was free, the expenses being met by the state board of health and the Federal Bureau of Maternal and Child Welfare. To date only a course in obstetrics has been given. County societies have cooperated in organizing this program.¹⁸

New Jersey—Postgraduate extension courses are given under the auspices of Rutgers University which has had charge of the paper work, advertising, canvassing in county medical societies and the like. The regents of the state advanced \$10,000 for this work permitting lectures to be given for \$15 a course and \$25 for two or more courses (\$30 was charged before this appropriation was made). In 1932, instructors were paid \$50 per lecture regardless of the number in attendance. In 1932 820 physicians (almost one third of the total membership) enrolled in twenty-five classes at thirteen centers, courses were given by seventy-seven different instructors—thirty-three from New York one from Newark one from Boston, forty-two from Philadelphia. Courses consisted of fractures, applied neurology, newer drug therapy, traumatic surgery, gynecology, medicine recent advances in medicine, recent advances in surgery, pediatrics, gastro-enterology and obstetrics. In 1933 the same number of courses were given in the same centers, the registration shrank to 600 and since no appropriation was made by the state, the lecturers received \$35 per lecture in order that the lectures might be given to the doctors at the same rate.¹⁹

New York—The "Brooklyn idea" was originated in 1922 by the Medical Society of the County of Kings in cooperation with the Long Island College Hospital. Two extension courses in sections of ten each were given in the spring and fall, on Fridays at 5 p. m. From 400 to 500 physicians usually attended these courses. They also developed a seminar course limited to from four to eight students covering a weekly session of half a day or a full day each week for six weeks.

The extension courses comprised from eight to twelve hours of work, from one to three hours being spent at a hospital in the late afternoon one day each week. Attendance was limited to ten students. Similar work has been carried on by other county societies in New York State.

The state medical society, through its committee on public health and medical education, has conducted one or more six weeks courses in nearly every county of the state. Provision has been made for single lectures or for courses of any length (lectures or lecture and clinic) desired. Their aim is to raise local standards of practice.²⁰ Instructors are paid \$25 per session, plus traveling expenses.

The Medical Society of the State of New York through its committee on public health, has also conducted annual extension courses since 1927. Instruction has been given in from twenty-two to thirty-one counties during this period. That these courses have real value is evidenced by the repeated requests for courses in counties from year to year. The accompanying statistical table taken from the report of the committee for 1931-1932 gives an interesting summary of this work.

This is a major project in medical education, the committee has increased its usefulness to practicing physicians by arranging special one and two day postgraduate courses at various medical schools in New York State. The expense is met by an appropriation from the state society.

Comparative Summary of Work in Graduate Education Under the Auspices of the Committee on Public Health and Medical Education for the Past Four Years

	1927-28	1928-29	1929-30	1930-31	1931-32
Total number of courses	214½	214½	16	21	20
Total number of lectures	116	10½	91	110	115
Number of county medical societies before which courses were given	22	21	19	2	2½
Total attendance of all courses	3 268	4 809	3 296	3 520

North Carolina—Extension courses first started in 1916 through the cooperation of the state medical society, the state board of health and the state university, but they were discontinued during the World War. In 1922 extension teaching was resumed by the University Extension Division and the University of North Carolina School of Medicine and was given every summer until 1929. Classes were organized on the circuit plan, each class meeting once a week for from six to twelve weeks. One instructor taught the entire course or three gave instruction for one month each. These doctors were always chosen from outside the state. In eight years there was a total enrolment of 1,341 doctors, whose average attendance was 72.2 per cent. The director of the extension division feels that they lacked funds to provide the best possible teaching service also, they were unable to reach physicians in remote rural sections because of the necessity of locating classes where the largest enrolment could be secured (in order to finance the work). Tuition ranged from \$25 to \$40 depending on the length of the course.²⁰

Ohio—The state medical society has, for several years, cooperated with the medical schools of the three universities in Ohio in creating interest among its members in a series of postgraduate lectures arranged by those schools each year. A committee from each of the schools assists the county medical societies in arranging programs.²¹

Oklahoma—Extension courses have been given by the extension division of the state university in various centers usually grouped conveniently for instructors' travel fees ranged from \$10 to \$35, courses have been given in cooperation with the

state medical association, although some were given entirely under the supervision of the school of medicine and the extension division of the state university. Members of the faculty have been paid only expenses in the form of honorariums except that when an instructor has been employed on full time for from one to two months he has been paid from \$750 to \$1,000 per month, plus expenses. These courses have been discontinued because the governor of the state withdrew financial support from this division of the state university, also, the entrance of the osteopathic profession to these state-controlled courses caused the immediate cessation of the courses in October 1933.²²

Pennsylvania—The state society does not conduct postgraduate courses as such. An annual councilor district meeting is held by each of the eleven councilor districts, at which one or two out-of-state doctors speak. All expenses are paid by the state society. A number of the sixty component county societies conduct graduate courses.²³

Virginia—The Medical Society of Virginia began extension teaching in 1929 with the appointment of a committee known as the Department of Clinical Education, whose purpose it was to stimulate educational programs on the part of local medical societies and to furnish competent clinicians. They have had an annual appropriation for three years of \$500 from society funds (used for traveling expenses of speakers and for publicity). Later the Department of Clinical Education formed a joint committee on prenatal and postnatal instruction with the Medical College of Virginia and the University of Virginia, with the University Extension Division as the administrative agent. The program of the joint committee was underwritten by a grant of \$2,500 from the medical society and a grant of \$10,000 from the Commonwealth Fund of New York for the first year, with \$5,500 available for the second year. The tuition fee for the course of ten lectures was set at \$5.²⁴

Washington—The state medical society endorses an annual course given by the University of Washington. The usual charge is \$15 for four or five lectures given within a period of one week. The average annual expense is \$2,500, the average attendance is 230.²⁵

Wisconsin—Postgraduate extension teaching was begun on the North Carolina plan in 1917 but was soon changed to the holding of lectures and clinics at any point in which a group organized and asked for them. The Wisconsin Medical Society, the extension division of the University of Wisconsin and the University of Wisconsin Medical School cooperated to give medical extension courses. The tuition fee for the courses offered has been \$30 for a series of twelve weekly meetings of two hours each. An advisory committee met twice a year and worked out general plans for courses, the details and budget responsibilities were carried by the extension division, \$3,000 per circuit of twelve weeks was collected which covered the salaries and expenses of the instructors. It was not planned to give the extension courses in 1933 owing to the financial condition of the area.²⁶

This information makes no effort to include stated meetings, symposiums, conventions, local medical clubs and the like, all of which are worth while and often educational organizations of high merit. It is necessary to broaden the base of education if the general level of medical service is to be raised. Extension courses help to do this and at the same time present a sound method of helping the individual, they should also educate the profession to the need of systematic resident study at some school. When the profession demands better postgraduate facilities I feel sure that the public will assist in providing the means even as they have for the undergraduate courses.

SERIOUS ARSPHENAMINE REACTIONS WITH REFERENCE TO THEIR PREVENTION

REPORT OF SIX CASES

MAXWELL SCARF, M.D.

PHILADELPHIA

In the past five years I have observed six severe accidents following neoarsphenamine therapy. With the exception of case 4 (service of Dr S. S. Greenbaum), all were in the service of Dr Henry B. Shmookler. They constitute a unique assortment of cases, representing as they do every type of serious reaction except exfoliative dermatitis, which may, and frequently does, prove rapidly fatal. The literature on the subject is not so opulent as to make the report of these cases merely supernumerary. Especially is this true of complications such as aplastic anemia (case 1) and transverse myelitis (case 5). Indeed, the universal use of the potent arsphenamines invests this subject with a ubiquitous timeliness. The purport of this report is not, however, to augment the literature with additional case records. It is, rather, to review these cases from the standpoint of prevention and to dissipate the fatalistic notion, held by many, that most if not all disastrous reactions are inevitable. An attempt will be made to show that in four of the six cases cited here the sinister event might have been obviated by the cognizance of apparently innocuous symptoms and signs as the harbingers of impending danger. It may be said briefly that in the therapy of syphilis it is imperative to be conversant with and alive to the significance of minutiae.

APLASTIC ANEMIA

CASE 1—Mrs. S. L., aged 30, admitted to the hospital, Dec. 29, 1931, for severe headaches of ten weeks' duration, had a strongly positive Wassermann reaction. A roentgenogram showed six circular areas of bone absorption, about 1 cm. in diameter each, in the frontal bones of the skull. Treatment with iodides and with compounds of mercury and bismuth relieved the headaches. After discharge she received twelve injections, at weekly intervals, of 0.6 Gm. of neoarsphenamine. Two weeks prior to her last injection she noted a blue mark on the thigh. An injection was given. One week later a crop of these appeared. This finding was blissfully disregarded and another injection given. Following this, severe purpura occurred. Concomitant with the purpura generalized mucous membrane bleeding appeared as epistaxis, hemoptysis, menorrhagia, melena and retinal hemorrhage. On readmission, May 13, 1932, pallor was extreme. The blood count showed hemoglobin, 36 per cent, red blood cells, 1,690,000, white blood cells 4,700, polymorphonuclears, 44 per cent, small lymphocytes, 55 per cent, platelets, 70,000. No abnormal cells were seen. Reticulocytes were 1 per cent. The icterus index was 6. The bleeding time was forty-seven minutes and the coagulation time, four and one-half minutes. The urine was positive for arsenic. The Wassermann test was now negative. A diagnosis of postarsphenamine aplastic anemia was apparent. During her three months hospital sojourn she received eleven transfusions, about 500 cc. each, the blood count rising to hemoglobin 76 per cent, red blood cells, 3,700,000, white blood cells, 5,700, polymorphonuclears 51 per cent, lymphocytes, 49 per cent, platelets 80,000. Follow up six months later showed complete restoration of the blood to normal.

An anemia in which the hematopoietic system is so suppressed and paralyzed that it causes a marked reduction in all blood elements is aplastic. Of the cases that occur, those that are secondary to roentgen, radium, benzene, trinitrotoluene and arsphenamine poi-

soning outnumber the idiopathic form. In 1919, Labbe and Langlois¹ first described postarsphenamine aplastic anemia as an entity. The condition is rare. McCarthy and Wilson² recently reviewed seventy-nine cases of blood dyscrasias following the arsphenamines, thirty-four of which were aplastic anemia. Phelps had two cases out of 272,354 doses. Stephens reported this complication twice in a series of 14,000 injections given to 1,200 patients. Combes³ had one in 4,000 patients. Farley⁴ in seven years, saw six cases.

Of the various arsphenamines used, neoarsphenamine is responsible for about 65 per cent of the cases, not because of its more peculiar toxicity but probably because of its more frequent use. Sulpharsphenamine is the arch offender. Indeed, Stokes⁵ has said "I have never seen a case of aplastic anemia in an experience numbering more than 100,000 injections until I began to use sulpharsphenamine. Then, like a thunder-clap, within a short period of several months, I saw five cases in rapid succession, all due to this drug." Bickford and Tilgham⁶ also think that relative to the total use of sulpharsphenamine, blood dyscrasias follow in its wake with surprising frequency.

The exact pathogenesis of the blood dyscrasias following the arsphenamines is still a mystery. The prevailing opinion incriminates the double benzene ring of the organic arsenicals as the injurious agent. This is predicated on the well known marrow-depressing effect of the benzenes. It is also pointed out that Whelan's case of granulopenia in a child is the only one on record due to inorganic arsenic. Opposition to this theory is based on the uncertain knowledge that benzene actually splits off and that, if it is so liberated, its quantity is less than studies have shown necessary to produce such toxic effects. Some believe it occurs only in patients with a congenitally weak hematopoietic apparatus, since, in comparison with the wide use of the arsphenamines, aplastic anemia is rare. Bronfin and Singerman⁷ postulate an idiosyncrasy. This idiosyncrasy may be reflected in the entire hematopoietic system as an aplastic anemia or, by selectivity, in any of its component parts, producing granulopenia or thrombocytopenic purpura as the case may be.

There is no way of predicting the onset of this disease in a syphilitic patient receiving the arsphenamines. It may follow the initial dose, exceptionally, or any one of the subsequent doses. It may follow within twelve to twenty-four hours after an injection, or it may be delayed for several months.

The death rate is exceedingly high. Loveman⁸ cites it as 60 per cent. In the thirty-four cases collected by McCarthy and Wilson,² the mortality was 83 per cent. Death is not immediate and is due either to repeated hemorrhages or to intercurrent infection consequent on the granulopenia. Recovery, when it does occur, is prolonged and tedious and averages about six months.

The sheet anchor of treatment is repeated transfusions with the objective of tiding over the patient until his own bone marrow begins to regenerate. Duke⁹ says that the bone marrow is architecturally simple and can regenerate readily, even if there is marked destruction, provided it gets rid of the primary cause. Farley⁴ believes that in many cases there is no actual aplasia but a physiologic paralysis.

In view of the high mortality rate, it is obvious that prophylaxis, when possible is of paramount importance. In case 1 the purpuric spots were ignored and not regarded as the danger signals, which they truly were. Misinterpreting their significance resulted in two additional injections, which converted into a severe and potentially fatal aplastic anemia what might have otherwise remained a benign and transient purpura simplex. Semenza¹⁰ recognized the gravity of such neglect and urged the systematic examination of the blood even in the absence of untoward clinical manifestations, an opinion concurred in by Bronfin and Singerman.⁷ Probably this is not practical. But it is essential, if one wants to avoid an occasional critical issue, to be vigilant and to assess any apparently trivial symptom or sign carefully and scrupulously.

HEMORRHAGIC ENCEPHALITIS

CASE 2—H. F., a man, aged 30, presented a swollen and painful left ankle joint on admission to the hospital. He had contracted gonorrhea three years before and had had a recurrent urethral discharge since. The ankle joint had been incised before admission and there was still considerable drainage of pus. A gonococcus complement fixation test was positive. The temperature and pulse were only slightly elevated. After conservative treatment for four weeks the ankle joint improved greatly but the left wrist became inflamed. Because of this metastasis a therapy sterilisans magna in the form of neoarsphenamine was thought worthy of trial, despite the negative Wassermann test. Accordingly, neoarsphenamine 0.3 Gm was given, March 2, 1928. A macular rash appeared on the face and neck a few hours afterward but was transient. March 9, 0.45 Gm of neoarsphenamine was administered. Twelve hours afterward the temperature rose to 104 F and vomiting occurred. The temperature fluctuated at this level and then abruptly rose to 106. The patient became irrational, had generalized convulsions and remained stuporous until his death, March 17. Several lumbar taps were performed, the fluid at first remaining clear and later containing many white cells. No arsenic was obtained in the spinal fluid. Necropsy showed an acute edema of the brain, congestion over the choroid plexus and petechiae in the left basal ganglions.

The distinctive destructive effects of the arsphenamines on the nervous system is expressed by a hemorrhagic encephalitis. In 1911, just a few years after the introduction of the arsphenamines into general use, the first case was reported by Fisher.¹¹ Of all the arsphenamine reactions, it is the chief cause of death, exceeding exfoliative dermatitis and acute yellow atrophy combined. According to Meierowsky and Kretzner, who reviewed 109 arsphenamine fatalities, 60 per cent were due to encephalitis. Of the twelve deaths reported by Cole, DeWolf and their associates,¹² six were due to this relentless complication. Of thirteen arsphenamine deaths reported in New York State¹³ from 1926 to 1931 inclusive, two were due to encephalitis. It is,

however, by no means of frequent occurrence Stokes¹⁴ had only one case in 63 000 injections Moore quoted by Brittingham and Phinzy,¹⁵ did not see a single case in 200,000 injections given to 15,000 patients

Hemorrhagic encephalitis is a grave complication Death ensues within several hours of the onset or may be delayed for a few days It has been reported as early as one hour after injection Only occasionally does a patient survive Sheppe¹⁶ tells of a patient who, three hours after injection, became drowsy, convulsive and unconscious but recovered Beeson¹⁷ also cites a case of hemorrhagic encephalitis with recovery Neoarsphenamine is responsible for more cases than arsphenamine, and sulpharsphenamine is the most culpable, comparative to its use It occurs in young adults early in the course of treatment, usually before the fourth injection Its onset is sudden and is characterized by headache, apathy, convulsions and coma The picture is similar to that of alcoholic wet brain¹⁸ Pathologically, the brain presents marked edema with extreme diffuse capillary hemorrhages, especially in the regions of the fourth ventricle, pons and corpus callosum Ehrlich¹⁹ thought that the dilatory and destructive effects of the arsphenamines on the brain were due to insufficient epinephrine as a result of simultaneous arsenical destruction of the suprarenals Since then, frequent doses of epinephrine have constituted the accepted treatment

Case 2 may be viewed in two antithetical ways Since hemorrhagic encephalitis is a sudden, unforeseen and unpredictable catastrophe, it may be maintained that the death was doubtless unavoidable On the other hand, it should be remembered that the Wassermann test was negative and that neoarsphenamine was given solely to combat a clinical gonococcemia The question is whether the efficacy of the arsphenamines in septicemias is so established as to warrant their use in these conditions Those who doubt this may well contend that no drug capable of creating such havoc should be used in disease states in which its beneficence has not been proved From this angle, the death may with some justification be considered avoidable Furthermore, it should be recalled that the initial injection of 0.3 Gm. was followed by a maculopapular rash which may have signified some intolerance to the drug and, at the very least, contraindicated an increase in dosage to 0.45 Gm. for the following injection

ARSPHENAMINE HEPATITIS

CASE 3—Mrs R. R., aged 25 had a history of two miscarriages and a positive Wassermann test She had received, in another institution, four injections of neoarsphenamine at weekly intervals, the last dose being given two weeks prior to her admission Her presenting symptoms were intense pruritus and jaundice It is important to note that the itching antedated the final injection Examination revealed diminution of liver dulness The icterus index was 72 The van den Bergh test gave an immediate direct and biphasic reaction Urobilinogen was positive in the urine in 1:160 dilution There was bile in the urine The latter was positive also for arsenic With liberal daily dextrose injections intravenously including a 50 per cent dextrose venoclysis for twenty-four hours she made a complete recovery within a month after admission

CASE 4—C. W., a man, aged 28, after exposure to a known syphilitic person developed a generalized papulosquamous syphilis, especially affecting the palms and soles The Kolmer and Kahn tests were strongly positive, Jan. 4, 1932 On that day 0.3 Gm. of neoarsphenamine was given January 7, 1 cc. of bismo-cymol was administered January 11, 0.45 Gm. of neoarsphenamine was injected Two days afterward, nausea, vomiting, headache, malaise and generalized erythema appeared The liver became palpable and a deep jaundice followed The icterus index was 63 Therapy consisted of injections of a bismuth compound and sodium thiosulphate The jaundice completely disappeared within two months

Syphilis, untreated, may be complicated by liver damage In the secondary stage, when the organisms are widely disseminated, the liver is the depot of a great horde of spirochetes This manifests itself in a mild, transient icterus and rarely, when the spirochetemia is massive, in an acute yellow atrophy with fatal outcome²⁰ Latent syphilis may also cause liver destruction either as a diffuse hepatitis, gummatous formation or cirrhosis Jaundice was a prominent symptom in the 140 cases of syphilis of the liver reported by O'Leary²¹ It must be remembered that many cases of syphilis of the liver remain unrecognized because, as Mann²² has shown, 90 per cent of the organ may be destroyed before the symptoms of hepatic insufficiency intervene It is always necessary to differentiate the cause of jaundice in any syphilitic patient treated with the arsphenamines as to whether it is syphilitic in origin or due to the drug Scott²³ contends that jaundice in early syphilis is of two types (1) syphilitic, in which the jaundice occurs as the result of liver cell degeneration before treatment begins, and (2) combined syphilitic and arsenical, in which the causative factor is principally the syphilitic infection, on which is superimposed the toxic action of the arsphenamines

It is interesting to note that experimentally marked hepatitis by the arsphenamines can be produced only in syphilitic and not in normal animals There is indubitable proof, however, that the arsphenamines do have an especially hepatotoxic factor

That the arsphenamines and not the arsenic is the probable cause of hepatic insufficiency is deduced from the comparatively few cases of jaundice reported before the extensive use of the former Filhol,²⁴ in reviewing this subject, ascertained the fact that icterus in syphilis was uncommon before the introduction of the organic arsenicals According to the Salvarsan Committee,²⁵ evidence is accumulating that arsphenamine therapy is followed in practically every instance by a certain degree of hepatic insufficiency susceptible of recognition by special tests, such as the icterus index, although clinical signs of disorder may be absent Cole, DeWolf and their associates²⁶ noted icterus in twenty cases in a series of 1,212 patients, with one fatal outcome In a recent report on a series of 10,021 patients, Wile and Sams²⁶ showed the incidence of postarsphenamine jaundice to be seven times as great as pretherapeutic jaundice

All writers agree that the occurrence of jaundice contraindicates the use of the arsenicals Even in the

absence of jaundice, if any liver damage is suspected the use of the arsphenamines should be interdicted as a dangerous drug. That itching often precedes the onset of jaundice is a point of singular relevancy. It will be remembered that patient 3 was given one dose of neoarsphenamine after itching had already insinuated itself into the clinical picture. That this additional dose might have precipitated the hepatitis, certainly aggravated it, is beyond doubt. Here again emphasis must be placed on the formidable significance of an innocent symptom, disregard of which may render one injection of a useful drug into a powerful weapon of destruction.

TRANSVERSE MYELITIS

CASE 5—Mrs. E. K., while hospitalized for a disorder in the upper part of the abdomen, was found to have a positive Wassermann reaction on two occasions. Two doses of 0.45 Gm. of neoarsphenamine were administered, one week apart. On the afternoon following the second dose the temperature rose to 103 F., the pulse became rapid, and pain in the upper part of the abdomen associated with vomiting occurred. The fever continued and two days later a diffuse macular rash appeared over the entire body. The following day she complained of pain in both legs and moved them with difficulty. This soon developed into a complete flaccid paralysis of both lower limbs. There was also sphincteric involvement with complete retention of urine. The spinal fluid showed 25 white blood cells and the Wassermann reaction was strongly positive. The paralysis was due to a transverse lesion localized around the mid-dorsal region and was considered as a focal reaction or therapeutic shock. Antisyphilitic treatment in the form of iodides and compounds of bismuth and mercury was intensively applied and, in spite of the gloomy prognosis, gradual recovery fortunately ensued. Nine weeks after admission the patient was able to walk, and sphincteric control was completely regained.

This case of transverse myelitis represents the rarest variety of the arsphenamine complications. Its symptoms can hardly elude recognition. Curiously, cases presenting the symptoms of encephalitis occasionally show neuroscopic changes in the cervical cord alone. Spiethof and Frank, quoted by Soein,²⁷ have both reported such cases. Recovery is rare. Some cases become chronic but most terminate fatally as a result of bedsores, bronchopneumonia or an ascending paralysis. According to Rabut,²⁸ arsphenamine myelitis can be divided into three groups. Group 1 consists of those cases in which the symptoms appear almost immediately after an injection and may be accompanied by transitory pains in the legs or paraplegias, which disappear quickly, often in twenty-four hours. These cases must be considered as a radiculomedullary form of a nitritoid crisis. Four such cases are reported by Pinard.²⁹ Group 2 consists of those cases in which the symptoms are due to medullary syphilis, which is reactivated, precipitated or energized by the drug, i. e., a Herxheimer reaction or therapeutic shock. This appears in patients with acute secondary syphilis or in old syphilitic persons who have not been treated for a long time. Group 3 is composed of those cases in which the symptoms are due to the toxic action of the drug alone. Schmorl³⁰ reported several cases with numerous foci of softening in the spinal cord due to arsenical intoxication. Chiari³¹ described a case of

dorsal myelitis in which at autopsy he ruled out syphilis by the lack of inflammatory or exudative changes, embolism and thrombosis, by the absence of vascular changes and because of the purely necrotic appearance of the lesion concluded that it was due solely to arsenical intoxication. The existence of this group is doubted by many. Myelitis following the arsenicals is ascribed by Stokes,³² Newmark,³³ and Mingazzini³⁴ to therapeutic shock.

The question as to whether myelitis is due to an intoxication or to a Herxheimer flare up is not merely academic because it has an important bearing on treatment. If toxic further arsenical treatment must be omitted, if a Herxheimer flare up, permissible and indicated. Devic reported a case in which continued arsphenamine treatment ultimately yielded a cure. Pinard's²⁹ cases improved with arsphenamine therapy. Greenbaum advised further treatment with arsenicals in case 5 which, however, showed complete disappearance of symptoms under preparations of bismuth and mercury and the iodides alone.

ANEURYSM OF THE AORTA WITH RUPTURE

CASE 6—S. N., a man, referred to the medical clinic, March 29, 1932, complained of a burning sensation in the region of the upper sternum. He had received, in the skin department, two injections of 0.45 Gm. of neoarsphenamine March 21 and 28. He gave a history of a penile lesion in 1922. The Kolmer and Kahn tests were strongly positive. Examination disclosed increased supracardiac dulness and a systolic murmur at the base transmitted to the carotids. Aneurysm of the arch of the aorta was suspected. An order for a roentgenogram of the chest was not consummated. Nevertheless, April 4 he received another dose of 0.45 Gm. of neoarsphenamine. That day severe precordial pain developed. April 6 he walked five blocks to the hospital, where, on his arrival, he was seized with an agonizing stenocardia, after which symptoms of profound shock supervened. Orthopnea was extreme. The following day he died during another attack of precordial pain. Necropsy showed a large saccular aneurysm of the arch of the aorta which had ruptured into the mediastinum. The coronary arteries were normal.

That aneurysms may rupture spontaneously is, of course, indisputable. It may be argued, then, that the rupture of the aneurysm was merely coincidental with the arsphenamine therapy, thus denying the apparent relationship of cause and effect. The occurrence of rupture following quickly on the heels of vigorous antisyphilitic remedies has so often been noted, however, that it inveighs heavily against such an assertion and makes it well-nigh untenable. Stokes³² had two deaths from ruptured aneurysm within twenty-four hours after injection. It is because of such notoriously appalling effects, which some practitioners experience while others do not, that the literature on the subject of treatment of cardiovascular syphilis is so chaotic and confusing. After careful scrutiny, two main currents of thought can be distinguished. One consists of the belief that by the use of arsphenamines better results can be achieved than without them. Moore and Dangle³⁵ state that the duration of life in their patients so treated was sixty-nine months as compared with nine months in untreated patients. Similar results

were obtained by Pinaud³⁷ and by Conybeare³⁸. Notable success has also been reported by Cotton³⁹ and by Hazen⁴⁰. Keidel and Kemp⁴¹ do not deem the poor prognosis in aneurysmal dilatation a deterrent to the use of the synthetic arsenicals. Vaquez⁴² says "In severe cases of cardio-aortic syphilis there should be no hesitation in resorting to neoarsphenamine. I have used it frequently without harm." Sir Thomas Lewis⁴³ is not averse to its use. None of these men fail to stress that very small doses should be given. It is especially noteworthy that practically none had the temerity to administer the arsphenamines without an adequate preliminary treatment with iodides and mercury or bismuth compounds. Smith⁴⁴ emphasizes the particular importance of precluding the possibilities of therapeutic shock by using the milder antisyphilitic treatments before arsphenaminizing the patient. East and Bain⁴⁵ recommend the prolonged use of iodides and mercury compounds as a wise precaution and necessary procedure.

The men who hold the second opinion believe that the use of arsphenamines in cardiovascular syphilis is positively dangerous and sedulously avoid them. That more harm than good can result from intensive measures is asserted by Warfield⁴⁶. Meyer⁴⁷ describes examples of fatalities from the rapidly acting arsphenamines. That arsphenamine makes aneurysmal cases worse is contended by Bullrich⁴⁸. Donzelot⁴⁹ concurs with him fully. Coombs⁵⁰ voices a definite objection to the use of the arsphenamines in advanced aortitis. All these, and others, invoke to their aid the deaths reported from therapeutic shock and the therapeutic paradox.

When such decided difference of opinion exists it is perhaps wise to adopt a course between the two extremes. The keynote should be summed up in one word—conservatism. A sane middle course is charted by Paul White,⁵¹ who advises from six to eight weeks of mercury compounds and iodides to be followed by small doses of neoarsphenamine, beginning with a dosage of 0.1 Gm, cautiously increased to 0.4 Gm.

Was the death of patient 6 avoidable? The large initial dosage of 0.45 Gm of neoarsphenamine and the failure to prepare the patient for the reception of this drug by the use of milder antisyphilitic treatment compel an affirmative answer. This procedure violated the two important tenets on which there is virtual unanimity of opinion by those who advocate the use of the arsphenamines, namely small dosage and preparatory administration of the iodides and compounds of bis-

muth or mercury. The disastrous complication of ruptured aorta can be forestalled only by a discriminating use of the potent arsenicals in syphilis of such vital structures as the heart and aorta.

SUMMARY

1 One case of aplastic anemia developed under neoarsphenamine therapy when two injections were given after purpura appeared.

2 In one of the two cases of hepatitis, one injection of neoarsphenamine was given after the patient complained of itching.

3 Hemorrhagic encephalitis occurred as a complication in a case of gonorrheal arthritis with a negative Wassermann reaction in which two doses of neoarsphenamine were given in increasing doses, although an eruption followed the first dose.

4 In a case of aneurysm of the aorta, rupture followed neoarsphenamine therapy, which was too vigorous and not preceded by a preparatory course of the milder antisyphilitic drugs.

5 A case of transverse myelitis, due to a rare and usually fatal form of Herxheimer reaction, terminated in complete recovery.

6 A large proportion of fatal or disabling reactions may be prevented by a careful evaluation of symptoms and signs as they appear in syphilitic patients under treatment with the arsphenamines.

THE USE OF DIPHTHERIA TOXOID IN IMMUNIZATION OF MEDICAL STUDENTS AND NURSES

ALVIN E. KELLER, M.D.

AND

SEALE HARRIS, JR., M.D.

NASHVILLE, TENN.

The occurrence of diphtheria in medical students and nurses is a significant problem. While the susceptibility rate in this age period is not as high as in children under 10 years of age, the number of susceptibles among individuals 20 years of age and older is sufficiently high to warrant an attempt at immunization, especially since they are exposed frequently to this disease. Toxin-antitoxin has been usually employed in the United States for immunization of students and nurses against diphtheria. The experience with toxin-antitoxin in the immunization of nurses in the Vanderbilt University Hospital has not been satisfactory in that nine out of twenty-four Schick positive nurses receiving from three to four doses of toxin-antitoxin gave a positive reaction approximately six months after receiving the injections, and one of the group developed nasal diphtheria following three doses of toxin-antitoxin.

The effectiveness of this agent has varied in producing immunity. From 50 to 75 per cent of children given three injections have been reported by Park and Schroder¹ as showing a negative Schick test following immunization. Volk² has reported that 65 per cent of 8,000 children given three injections of 1 cc each of

toxin-antitoxin mixture were immune at the end of one year. He advocated giving four doses of toxin-antitoxin, and by this procedure a higher percentage of children were Schick negative at the end of one year as compared with a similar group given three injections of toxin-antitoxin. In his investigations, 64.4 per cent of children given three doses of toxin-antitoxin were Schick negative at the end of one year and 85 per cent were negative at the end of two years. Following four doses of toxin-antitoxin, 74 per cent were Schick negative at the end of one year and 92 per cent were negative at the end of two years.

Rhoads³ has reported that fourteen of twenty-nine cases of diphtheria in nurses occurred in those who had received from three to six injections of toxin-antitoxin from three months to two years prior to the onset of the disease. He emphasized the variation in potency of the different brands of toxin-antitoxin in use at that time. Lintz⁴ has reported a reversal of the Schick reaction in 55.4 per cent of a group of nurses who had received five injections.

Harrison,⁵ in a carefully controlled investigation, has shown that following three injections of 1 cc each of toxin-antitoxin mixture, standard strength, 65 per

cent of children became Schick negative, while under similar conditions in another comparable group of children 95 per cent became Schick negative following two injections of diphtheria toxoid. The Dicks⁶ in 1929 emphasized the advantages of toxoid in the immunization of adults against diphtheria. They reported that diphtheria toxoid as prepared by Ramon and given in three doses was a better immunizing agent than 0.1 L + diphtheria toxin-antitoxin mixture even when five doses of the latter were given.

The advantage of diphtheria toxoid as compared with toxin-antitoxin mixtures as an immunizing agent are well known. Its use, however, has been confined mainly to children under 8 years of age, owing to the severe local and general reactions that have been reported in older persons. For immunization of older children and adults, toxin-antitoxin is still advocated. Owing to the relatively low percentage of individuals immunized and the variation in potency of toxin-antitoxin, its effectiveness in the immunization of young adults is probably not as great as in children. It is also likely that young adults are more refractory

to immunization, since the susceptibles in that age period represent those who have failed to become immunized through natural processes. For the past few years an average of 28.8 per cent of medical students at the Vanderbilt University School of Medicine and 24.2 per cent of nurses at the Vanderbilt University School of Nursing have been found to be susceptible to diphtheria as determined by the Schick test. A control test with heated diphtheria toxin was done on each individual tested as we were dealing with an age group in which pseudopositive reactions were more likely to be found than in children. It was decided to immunize the positive reactors with diphtheria toxoid by the method advocated by the Connaught Laboratory in Canada. The toxoid (anatoxin-Ramon) and dilute toxoid were obtained from the Connaught Laboratories of the University of Toronto.

In order to avoid severe local and general reactions, the toxoid skin reaction test was given to each positive individual before any immunizing substance was injected. This test consists of an intradermal injection of 0.1 cc of a 1:10 dilution of toxoid. If no reaction consisting of an area of redness more than one-half inch (13 mm) in diameter developed within three days, the individual was given undiluted toxoid in the usual dosage. If a skin reaction did occur, increasing doses of diluted toxoid were given.

The results reported in this study were obtained over a period of one year. Only those persons who had a positive Schick test were immunized, the control test with heated toxin being negative in each instance. Before immunization was begun, each individual was given a test dose of 0.1 cc of a 1:10 dilution of toxoid. The results in each group were the same, so that the analysis for the combined group will be given. Those who reacted to the toxoid skin test were given diluted toxoid and those who showed no reaction were given undiluted toxoid.

During this period, forty-six medical students and twenty-six nurses were given from two to four injections of toxoid. Those receiving undiluted toxoid were given three injections at intervals of three weeks, beginning with 0.3 cc for the first dose, 0.5 cc for the second and 1 cc for the third dose. This was the usual procedure with respect to undiluted toxoid except when there was any complaint as to the severity of the previous reaction, under which circumstances the dose was reduced. The first dose of diluted toxoid given to the "reactors" was 0.2 cc. Each successive dose was usually double the previous one unless the reaction was severe enough to be of significance. The entire group was retested with the Schick and control tests from three to six months following the last injection.

Of the seventy-two individuals immunized, fifty-nine received undiluted toxoid and thirteen received diluted toxoid. The results obtained with these agents are shown in the accompanying table. The actual amount of toxoid given to each individual is reported in order to show the response to small doses of this agent. Of the seventy-two individuals immunized fifty-nine, or 83 per cent, received toxoid in amounts varying from 0.8 to 1.8 cc in two or three doses and in all of them a reversal of the Schick test occurred in from three to six months from the date of last injection. Of the thirteen persons receiving toxoid in small amounts, twelve were given from 0.1 to 0.24 cc in three or four doses and a reversal of the Schick test occurred in each one within the same time limits. One nurse received

6 Dick, G. G. and Dick, Gladys H. Immunization Against Diphtheria. Comparative Value of Toxoid and Toxin Antitoxin Mixtures. J. A. M. A. 92:1901-1903 (June 8) 1929.

0.07 cc of toxoid in three doses and a negative Schick test was obtained following these injections. She had a positive Schick test two years prior to the present immunization and had received one injection of 1 cc of toxin-antitoxin at that time. She was not given any further injections of toxin-antitoxin because of the severe reaction.

The experience in this series in those individuals receiving small doses of toxoid is in agreement with that of Fraser,¹ who has reported a marked increase in the antitoxin response in certain persons who are skin sensitive to toxoid and who probably had prior to immunization, some antitoxin in the blood resulting from a previous primary stimulus. In one of Fraser's groups there were twenty-three persons whose diphtheria antitoxin titer was less than one-fiftieth unit per cubic centimeter of blood. Following the injection of from two to five small doses of toxoid, the antitoxin in titer was increased in all but one to the accepted level necessary to produce a negative Schick test. The total amount of toxoid injected in the present series of reactors was comparable to that injected in Fraser's series.

The reactions following these injections were on the whole mild. No student or nurse developed local or general reactions of sufficient severity to be absent from routine duties. Those in whom symptoms occurred complained of tenderness and pain at the site of injection, headache, slight to moderate rise in temperature, general malaise, and occasional abdominal discomfort. It was unusual for these complaints to incapacitate the individual and they cleared up as a rule within twenty-four to thirty-six hours, leaving only slight evidence of local reaction. The symptoms usually occurred after either the first or the second injection. It was not necessary to discontinue the injections in any one on account of undesirable reactions.

COMMENT

It is interesting that in every adult individual in this series a reversal of the Schick test from positive to negative occurred following injections of small to relatively large amounts of diphtheria toxoid in from two to four doses. The materials used were obtained from reliable sources and the toxoid and Schick testing material used was from the same lot and the testing and injections were done by the same persons. That the Schick test material used was potent is evident by the fact that positive tests were obtained in a group of children with the same material a few days before the present group was tested. Susceptible students were also tested with the same material and positive Schick tests were obtained. A majority of those who received the injections of toxoid were given another Schick test and each person was Schick negative on retest. The results obtained are in all probability due to the injections of toxoid, but one cannot altogether rule out the possibility that some degree of immunization resulted from contact with persons carrying diphtheria bacilli or with cases of the disease since the injections of toxoid were begun. While the latter is a possibility, most of the students and nurses in this series were either in the first or second year of their courses and the possibility of contact with cases of diphtheria was not as great as in students and nurses in the third and fourth years.

In the older age groups a control skin test should be done at the same time as the Schick test. Dilute toxoid may be used as control skin test material instead of heated diphtheria toxin, making it possible to determine susceptibility to diphtheria and at the same time to detect those persons who would develop undesirable reactions following an injection of toxoid.

CONCLUSIONS

1 The results reported show that it is possible to immunize students and nurses against diphtheria with diphtheria toxoid without producing any undesirable general or local reactions. The same procedure can be applied to the civil population under conditions in which immunization against diphtheria is indicated.

2 By testing intradermally with a skin test dose of dilute toxoid each person in the older age groups who has a positive Schick test, those individuals in whom a severe reaction would occur following a subcutaneous injection of toxoid can be detected.

3 Those who have a negative toxoid skin test can be given the usual dosage of diphtheria toxoid, while the dilute toxoid should be given to those who have a positive toxoid skin test or "toxoid reaction test."

4 These observations emphasize the desirability of using diphtheria toxoid to replace diphtheria toxin-antitoxin mixture as an immunizing agent.

THE PRESCRIBING OF DEXTROSE PHLEBOCLYSIS

BERNARD FANTUS, MD

CHICAGO

Dextrose phleboclysis¹ is, in certain conditions, a life-saving measure. It would be a shocking revelation could statistics be collected as to the number of people who annually die from hypohydration of the system, when their lives might have been spared by the parenteral administration of 5 per cent dextrose solution, of the number of patients lost from hypochloridation when dextrose-saline phleboclysis might have prevented their death, the number of ketosis deaths that might not have occurred had dextrose been given, and the occasional life that might have been saved by osmotherapy. What is no less pathetic is that, in instances lives are lost in the conditions mentioned even though dextrose solution was administered, simply because the patient was not given enough, or because the remedy was not employed early enough, or because the solution administered was not of the proper composition.

The reasons are not far to seek. Dextrose infusion has been but recently introduced into the practice of medicine, and there may be some physicians who still consider it a passing new fangled notion. Then there is the conviction that this is essentially a hospital procedure entirely unsuited to medical practice in the home. Likewise, the idea exists that it is impossible to secure properly prepared solutions in convenient containers for emergency administration in the home and that there are inherent difficulties in the procedure itself requiring meticulous technique difficult to master. That all these reasons are fallacious can be easily

¹ The term phleboclysis has been proposed by Reginald A. Cutting (The Place of Dextrose Phleboclysis in Surgery, New Orleans M. & S. J. July 1933 p. 239) instead of venoclysis which is a hybrid word, *vena* being of Latin and *clysis* of Greek derivation. It is also such time that at least in medical literature the word glucose which the U. S. Pharmacopeia applies to an impure product unsuitable for the purpose be abandoned for the pharmacopeial term dextrose.

¹ Fraser, D. T. The Response to the Injection of Small Doses of Diphtheria Toxoid in Man. *Tr. Roy. Soc. Canada* section V 1931 1: 191-195.

demonstrated As an abundant and ever increasing literature shows, the procedure is not only eminently rational but also supported by a mass of clinical experience, and the indications as well as contraindications are becoming well recognized Manufacturing technic has simplified the administration to such an extent that dextrose phleboclysis is not much more difficult or troublesome than the intravenous injection of an antiserum and is less dangerous Just as antitoxins are nowadays universally sold in syringe packages, so are these solutions available in containers ready for convenient administration, in practically every hospital, and they could be kept in drug stores, would the demand justify it

As the matter of the preparation and administration of the solutions is now well standardized,² space need not here be sacrificed in its discussion Suffice it to say that it is not so much "triple distillation"³ which is needed as that the water must be properly and freshly distilled just before final sterilization in order to avoid contamination with fever producing substances ("pyrogens") that may be produced in distilled water within a few hours by the growth of certain bacteria that it seems almost impossible to prevent getting into the fluid during the necessary manipulations This pyrogen readily passes over with the distillate in the ordinary still unless a water spray trap is employed during the distillation A single proper distillation will render water nonpyrogenic, while even after repeated ordinary distillation it may still be pyrogenic The rubber tubing should be rinsed with pyrogen-free water and properly sterilized shortly thereafter The ingredients employed in the preparation of the solutions must be chemically pure and free from contamination and caramelization The glassware should be "Pyrex" or Jena glass It has also been quite definitely shown that the rate of injection has a great deal to do with untoward reactions, and that the best way to prevent "speed shock" is by the drip method of administration, i e, that the individual drops be counted by means of a rectal drip bulb Hypertonic solutions should be given more slowly than isotonic solutions The solution in the container should, as a rule, be at 120 F and the container surrounded by a hot water bottle or similar device to maintain this temperature It will lose from 15 to 30 degrees F before it is delivered into the vein It must be assumed that all these matters are taken care of, so that attention may be directed here most especially to the prescribing of the proper composition of solutions to meet, with the smallest possible number of different stock solutions, the various individual indications of patients in need of this procedure

HYPOTHYDRATION⁴

As with other remedies, the dose of dextrose phleboclysis is "dose enough" and in this case quite a bulk, generally a liter The daily water turnover has been estimated at more than 16 liters This includes, of course, the secretions that are reabsorbed as well as the lymph that returns the water it drains from the blood When the ingestion of water becomes impossible, e g, after operations, it is difficult to supply water fast enough by rectal administration, subcutane-

ously or intramuscularly, and, if any degree of emergency exists, it must be given intravenously In this connection, the danger of delay and of dallying with methods inadequate to meet the situation must be pointed out Irreversible changes and vicious circles may become established When capillaries are insufficiently supplied with blood for some time, the increased vascular tone produced by vasomotor nerve excitation gives way to vasodilatation, probably from the local production of histamine-like bodies, and, in consequence of the action of these, the capillaries also become leaky, thus still further aggravating the deficiency of circulating fluid, still more depressing the low blood pressure and increasing the evil results of the general hypohydration An infusion given twenty-four hours too late may be incapable of relieving this vicious circle on account of irreversibility of the change It is necessary for the physician to be ever conscious of his patients' need of water For the maintenance of life, water is only second in importance to oxygen, and it is much more vitally important than food The responsibility rests with physicians and nurses of assuring the sick person a sufficient intake of fluid Just as the development of an "aseptic conscience" is a medical and surgical requisite, so medical people and surgical as well must be made "water-need conscious," whenever normal ingestion of fluid is interfered with

Normally, water enters the system only through the mouth, and, as soon as the patient cannot get all the water he asks for and still more especially if he cannot ask for it, care must be taken that he receives a sufficiency of it in some way or another In the conscious individual, thirst is a fairly delicate indication of hypohydration Considering the urgency of this sensation, mere humaneness should dictate its gratification Even more important is the fact that relief of thirst may mean the prevention of collapse A patient is therefore not properly cared for if he is permitted to suffer the torments of thirst Particularly serious is the fact that unconscious or semiconscious patients, as a rule, do not get enough water In all cases of serious sickness the best way of assuring an adequate fluid income is not only to prevent thirst but also to aim at an excretion of a quantity of at least 1,000 cc of urine in the twenty-four hours Whenever the quantity of urine falls below this, the nurse should call the physician's attention to this fact, and measures should promptly be instituted to correct the deficit, which should always be possible unless the kidney itself or its circulation is at fault The twenty-four hour quantity of urine should therefore be as regularly recorded in critically sick patients as is the pulse and temperature rate

The water should of course, be given by mouth, if possible, but conditions often arise when peroral administration is required Even if the patient can swallow, water does not quench thirst as long as it stays in the stomach, for the stomach does not absorb water Hence the patient in shock should be merely given sips of hot water frequently enough to minimize the suffering from thirst but not enough to distend the stomach, which may induce vomiting that aggravates the shock At the same time, adequate fluid income by other channels must be taken care of, for so-called secondary shock is often nothing more or less than hypohydration collapse, which might be prevented or lessened by giving, as soon as the primary shock is under control (and not before) retention enemas, or, if these are not successful, hypodermic, intramuscular

² Thompson S A Preparation of Dextrose and Saline Solutions and Apparatus for Intravenous and Subcutaneous Use *Am J Surg* 21 127 (Oct.) 1933

³ Elser W J and Stillman R G The Fetish of Triply Distilled Water *J A M A* 100 1326 (April 29) 1933

⁴ Hypohydration seems a better word to employ here than the more commonly used word dehydration because strictly speaking life would cease long before dehydration could occur

or intravenous injection of dextrose solution, in accordance with the seriousness of the emergency

It must be remembered that the sudden loss of 10 per cent of the water of the body results in serious disorders, and the loss of from 20 to 22 per cent means death. The daily intake probably cannot be reduced much below 600 cc for any length of time. The minimal desirable daily income of water may be estimated at 1.5 liters, but increased loss of water by sweating or purging increases the quantity required—may easily double it. Hence striving to secure the elimination of a sufficient quantity of urine is the most rational method of assuring adequate fluid intake.

Nothing seems more absurd than the thoughtless routine use of so-called physiologic solution of sodium chloride for the relief of thirst, or systemic hypohydration. Shipwrecked sailors have died from thirst with "water, water everywhere, nor any drop to drink." Even though 0.85 per cent salt solution is of much lower osmotic tension than sea water, the very fact that it is isotonic with the blood makes it that much less thirst quenching than plain water. Who would like to quench his thirst on a hot summer day with liberal libations of so-called physiologic salt water?^{4a} And that is what physicians treat their thirst tortured patients to. When, in the early days of its use, this solution was the normal (really decinormal 0.50 per cent) salt solution it was more thirst quenching than after it became known that, to be iso-osmotic with the blood serum, it had to be 0.85 per cent and was made to carry this concentration. Not only is this "physiologic" salt solution a poor thirst quencher, but when from 2,000 to 3,000 cc of it is given in twenty-four hours the kidney must eliminate this 17 or 25.5 Gm of sodium chloride, and, when the kidney is diseased or poorly supplied with blood this is a distinct burden to it and to the system. An isotonic sugar solution, on the other hand, releases the water associated with it the moment the dextrose is oxidized to carbon dioxide and water, which, being eliminated by the lungs, do not burden the kidney. The proper strength of this solution is in round numbers 5 per cent (more accurately, 5.1 per cent anhydrous dextrose). It preserves the shape of red blood corpuscles. In point of fact, the concentration that produces no observable change in the erythrocytes lies between 3.5 and 6 per cent.⁵ Laking occurs with concentrations below 3.5, and crenation appears at 7 per cent. Therefore, whenever it is necessary to combat hypohydration whenever one aims to quench thirst by intravenous injection, a 5 per cent dextrose solution should be infused. The temperature of the solution as delivered into the vein may range between 70 and 120 F. To patients with high temperature a relatively cool solution may be given which tends to lower body temperature. It also lowers blood pressure. Solutions above 98.6 F tend to raise blood pressure. In patients with subnormal temperature and most especially in shock, the higher temperature should be aimed at.

HYPOCHLORIDATION

Only second in importance to water in the medium surrounding the cells are the sodium and the chloride ions. When chloride deficiency in the system is spoken

of, a sodium deficiency is naturally also implied, for in the body the sodium ion occurs in an almost equivalent quantity (or rather in slight excess, in the form of bicarbonate). An elaborate mechanism exists to maintain the chloride percentage in the blood at a remarkably constant level (between 0.349 and 0.387 per cent). Nevertheless, hypochloridation of the system does occur, most especially after obstinate emesis, profuse diarrhea, extreme sweating or copious exudation, as in extensive burns. Haden and Orr⁶ have demonstrated conclusively the great remedial value of sodium chloride in the hypochloridemia of intestinal obstruction.

As in all these conditions a tendency to ketosis also exists, it seems reasonable to administer dextrose as a routine procedure along with the saline solution. On the other hand, it would be a serious error to administer dextrose solutions alone in conditions of hypochloridation, for dextrose phleboclisis tends to reduce the percentage of chloride not only in the blood but also in the lymph.⁷ Whenever salt starvation is present or threatened, dextrose-saline phleboclisis should be practiced, as pure dextrose solution increases the salt deficit. In order not to make the solution excessively hypertonic, its formula should be 5 per cent dextrose in physiologic solution of sodium chloride.

When much salt is lost, the secretory activity of the kidney becomes impaired and the quantity of urine is much diminished, nonprotein nitrogen retention occurring as a concomitant. Maintaining by means of dextrose-saline phleboclisis a liberal output of urine, from 800 to 1,000 cc in the twenty-four hours, enables one to feel secure that hypochloridation will not occur.

KETOSIS

Even more important than isotonicity is the maintenance of a certain hydrogen ion concentration of the blood. Stating it in another way, next to water and sodium chloride, a certain concentration of sodium bicarbonate in the blood is of the greatest importance. As acidosis is an extremely common pathologic state, more common than fever, it should be always looked out for and prevented in every case of serious sickness. The simplest way of recognizing acidosis and at the same time of lessening it, is to administer, at short intervals, just enough sodium bicarbonate or other alkali to make the urine amphoteric. When this is accomplished it is known that acidosis cannot exist and also that the patient has not been harmed by the production of an alkalosis. One should, in other words, as a routine take care of a sufficiency of sodium bicarbonate as one ought to take care of a sufficient supply of water.

It will be found, however, that in all conditions in which dextrose is inadequately catabolized whether this is in starvation or in diabetes, excessively large quantities of sodium bicarbonate would be required to secure this result and that even then the effect is merely temporary. One must in such cases proceed more fundamentally and relieve the cause of the acidosis by supplying dextrose, insulin or both. Indeed, one should not wait for the acidosis to assert itself. Whenever a patient cannot be given enough carbohydrate to prevent ketosis, one should provide it even before the condition asserts

4a. In conditions of extreme sweating as in blast furnace work on a hot summer day when the system loses a good deal of sodium chloride in the perspiration the addition of from 0.1 to 0.25 per cent of sodium chloride to the drinking water is advised but even under these conditions 0.85 per cent salt solution would be excessively salty.

itself, for acidosis creates a vicious circle. Thus it has been shown by Thompson, Mitchell and Kolb⁸ that artificially induced acidosis lessens carbohydrate tolerance, causing hyperglycemia. The younger the subject, the greater also the degree of metabolic activity, e. g., in hyperthyroidism or fever, the greater the tendency to ketosis, for which dextrose is the specific remedy. The quantity that can be given by hypodermoclysis is too small to be of any importance, as can be seen from the following figures. Assuming that 500 cc. of the 5 per cent solution is injected two or even four times daily, the 50 or 100 Gm. of sugar thus introduced would merely yield from 200 to 400 calories, but even this amount usually cannot be administered for more than two or three days, as the patient would then refuse further injections on account of the soreness produced in the tissues used repeatedly for this purpose. By intramuscular or, rather, epifascial injection, a 10 per cent dextrose solution can be injected into the muscles of the lateral and outer lateral surfaces of the thighs without a local untoward effect in quantities of 40 cc. for infants, and of 100 for children⁹ and of 500 cc. for adults. Four such injections a day would yield an adult 200 Gm. of dextrose or 800 calories, which might tide him over an emergency of a few days.

By dextrose phlebotomy, a 10 per cent solution can be introduced at the rate of 500 cc. an hour before the sugar tolerance of the average individual is overcome as evidenced by leakage of sugar into the urine. At this rate, more than 6,000 calories could be introduced in the course of twenty-four hours, which is twice as much as is required by the resting person. Hence it may be asserted that intravenous nutrition by means of dextrose phlebotomy is decidedly possible clinically, as is attested among others by Marriott¹⁰ as well as by Porter, Morris and Meyer¹¹. In view of this it should be inexcusable to permit a patient to develop starvation ketosis.

POISONING

It is of importance to distinguish between poisoning with diffusible and with nondiffusible bodies when "washing the blood" by means of phlebotomy is contemplated. While there is no doubt that in certain conditions of poisoning, brilliant results can be achieved by flushing the system with fluid, there is also no doubt that there are toxemias that give no such response, in which, indeed, heroic attempts in this direction are harmful to the patients. Thus in tetanus, in diphtheria, in pneumonia and in other infectious diseases it is impossible to detoxicate the patient by pushing fluid through the system, because these disease toxins are more or less colloidal nondiffusible principles. In the case of diffusible poisons, on the other hand, phlebotomy should not be spared. Discrimination as to the kind of solution to use is also here in order. In mercuric chloride poisoning, for instance, dextrose phlebotomy is probably of decided value. Whether sodium chloride should be used in the infusion fluid or not depends on the degree to which sodium chloride has been lost by the system in vomiting and purging. In the presence of nephritis, one should certainly be sparing with the use of salt.

Especially important is dextrose phlebotomy as a part of a liberal carbohydrate administration program in conditions associated with a tendency to acidosis and fatty degeneration, particularly of the liver, as in phosphorus, chloroform and cinchophen poisoning. Indeed, on the basis of the evidence of the value of dextrose in experimental poisoning, it is advocated in the treatment of liver disease in general.¹²

Whether isotonic (5 per cent) or hypertonic (25 per cent) dextrose solution shall be used should depend on the following considerations. If there is a probability that unabsorbed poison still exists at the point of its application, hypertonic infusion would be contraindicated, as it increases absorption, and 5 per cent dextrose solution should be used. When, on the other hand, this danger does not exist and one wishes to draw deposited poison back into the circulation, the use of 25 per cent dextrose phlebotomy is advisable, most especially in the presence of heart weakness or of pulmonary edema.

Every drop of fluid that is introduced by phlebotomy must be disposed of by the system in some way. Hence a check on fluid income and output is imperative. Under normal circumstances about 700 cc. of fluid is vaporized daily by lung and skin and about 300 cc. is lost in the feces. Hence approximately 1,000 cc. is taken care of by extrarenal elimination. This means that any quantity of fluid in excess of 1,000 cc. infused into the veins must reappear in the urine or be stored in the tissues in the form of edema, the initial stages of which may be clinically imperceptible even though harmful to the patient. Hence the total bulk of fluid infused daily should not exceed 1,000 cc. plus the quantity of urine. This would mean that if the patient cannot pass more than 1,000 cc. of urine, not more than 2,000 cc. of fluid can safely be injected into the vein during the twenty-four hours unless one of two conditions, or both, exist: 1. If there is profuse sweating, vomiting, diarrhea or exudation, such losses should be estimated and compensated for by increased quantity of fluid introduced. 2. When the system has lost much fluid, this loss is first made good before there is an increase in the quantity of urine. When, after an abundance of fluid has been given the body weight becomes stationary and the urine diluted, it is clear that the tissues of the body are saturated.

When the system has difficulty in ridding itself of fluid and dextrose is desirable for ketolytic or nutritional purposes, this is an indication for the use of concentrated, e. g., 25 per cent, dextrose solution. Otherwise the 10 per cent solution should be preferred, unless the chief indication is for the administration of water, when 5 per cent dextrose solution may be used.

The appearance of sugar in the urine, in the course of dextrose phlebotomy, means either cutting down on the introduction of the dextrose or the administration of insulin excepting in cases of poisoning, in which the diuretic action of the sugar is welcome.

DEXTROSE OSMOTHERAPY

The intravenous injection of greatly hypertonic (25 to 50 per cent) dextrose solutions should not be undertaken without definite demand for osmotherapy, i. e., the osmotic changes produced thereby in the system. One exception to this has just been noted. Another one is in private bedside practice, in which a physician may find it more practical to infuse slowly 20 cc. of

concentrated (25 per cent) dextrose solution by means of a syringe into a vein than to entrust drip phlebotomy to untrained attendants

In general, hypertonic dextrose phlebotomy is indicated only when one desires to secure from it changes in the salt and water content of the body cells, as in many cases chill and fever, sometimes of considerable degree, with severe headache produced by these injections. Hypertonic injection is also liable to lead to occlusion of the vein used for the infusion.

The "colloidoclastic" crisis due to destruction of a certain percentage of corpuscles and possibly of other tissue elements may be of advantage as a form of non-specific proteotherapy, e g, to stimulate latent powers of antibacterial resistance. It shortens the bleeding time and has been advocated by Opitz¹³ in internal hemorrhage. Lowy¹⁴ found this of value only in some cases of bleeding from the bowel.

The first capillary territory affected by hypertonic infusion is that of the lungs. This is the reason for Stejskal's¹⁵ report of favorable influence in pulmonary edema, whether of inflammatory or transudative nature, which has been confirmed by others. Litchfield,¹⁶ John,¹⁷ and Wells and Blankinship¹⁸ report favorable results from the use of large quantities (from 250 to 500 cc) of hypertonic (from 10 to 25 per cent) dextrose solutions in pneumonias.

Most marked seems to be the effect of osmotherapy in reducing intracranial pressure. Hypertonic salt solution has been used for this purpose, but Haden¹⁹ advocates the use of dextrose rather than of salt solution in cases of meningitis and other conditions of increased intracranial pressure. He infuses 250 cc of 25 per cent solution of dextrose (slowly in the course of one hour) every twelve hours, from the onset of the disease until there is no longer any evidence of excessive tension within the skull. In meningitis, these injections are given in addition to intrathecal injections of antiserum and combined with spinal fluid drainage. Its prompt use may save life in threatened cerebellar herniation into the foramen magnum.²⁰ In head injuries or after brain operations when slow pulse, low blood pressure and stertorous breathing indicate increased intracranial tension, hypertonic dextrose phlebotomy may be indicated, provided the emergency or other conditions preclude the giving of 30 cc of saturated solution of magnesium sulphate by mouth, or twice the quantity by rectum. It may, of course, be employed in addition to these measures. One should not, however, permit the use of these solutions to lead to a false sense of security in acute cranial injuries to the detriment of the prompt use of indicated surgical measures.²¹ It certainly should not be employed in the presence of intracranial hemorrhage.²²

Hypertonic dextrose phlebotomy seems to have a special value in heart weakness with or without edema.²³ In the presence of edema, absorption of intercellular fluid would no doubt account for part of this action. Its alleged value in myocardial weakness without edema, in which it is considered a useful adjuvant to digitalis, may possibly be explained by its demonstrated vasodilator action, which lessens the work the heart must do. In addition to this, the dextrose may furnish nourishment to the exhausted heart.

PHLEBOCLYSIS IN THE ADMINISTRATION OF REMEDIES

One of the most important uses of drip phlebotomy promises to be the administration of other remedies in a slow and continuous manner. Enormous doses of antiserums, e g, pneumococcus, tetanus, may thus be introduced, not only more easily but also more safely, because with extremely gradual administration there is no danger of anaphylactic shock.²⁴

The very slow injection of epinephrine solution directly from the tubing of the apparatus may be of some value as an analeptic. Adding epinephrine directly to the drip reservoir when it is full of fluid produces too great a dilution to be of much value as a vasoconstrictor.

Insulin may be added to the infusion fluid in diabetic coma or if undesired glycosuria occurs. In diabetic coma, it may be employed initially at the ratio of 1 unit of insulin per gram of dextrose. As soon, however, as the extreme emergency is past, it is probably better to administer the insulin subcutaneously, as when it is given intravenously, because of rapid elimination in the urine, its potency is less than when it is injected hypodermically.

In hyperthyroid crises, in the presence of persistent vomiting, sodium iodide (2 Gm) may be introduced in the course of dextrose phlebotomy.²⁵

Phlebotomy furnishes an ideal method of administering for very sick patients, as in these absorption on oral, and even on hypodermic, administration is notoriously uncertain. Morphine relieves pain more promptly, paraldehyde quiets mania more quickly, caffeine may arouse a comatose patient more definitely, and strophanthine stimulate the heart more efficiently than when given in any other way. When speed is essential, the drug may be injected directly into the rubber tubing after disinfection of its surface with tincture of iodine. The dose should, in general, be half the oral dose.

CONCLUSIONS

1 In all very sick patients an adequate income of water, sodium chloride and dextrose should be taken care of as a routine procedure before rather than after a high degree of deficiency has occurred.

2 This in cases in which adequate oral administration is impossible can generally best be accomplished by dextrose phlebotomy, the composition of which should be determined by the individual indications present.

3 For combating hypohydration and for the relief of thirst, 5 per cent dextrose solution in distilled water seems preferable.

4 Whenever salt starvation is threatened or present, dextrose-saline phlebotomy should be practiced.

STREPTOCOCCUS (VIRIDANS) MENINGITIS WITH RECOVERY

IMMUNOLOGIC STUDIES

JOSEPH FELSEN, M.D.

AND

A. G. OSOFSKY, M.A.

NEW YORK

The streptococcus is not commonly involved in meningeal infections, but the disease, when once in progress, is highly fatal. Kolmer,¹ in fact, has set the mortality rate at nearly 100 per cent. However, instances of recovery from streptococcal meningitis have been reported. Comprehensive reviews of the literature on this subject have been made by Rosenberg and Nottley² and by Appelbaum.³ The last named author was able to gather forty-six cases, including three of his own. Since his paper, eleven new cases have been added to the literature.⁴

A brief survey of the fifty-seven cases available for study shows the following facts. The onset usually followed an infection of the upper respiratory tract. The organisms that have been isolated include both the hemolytic and nonhemolytic types and *Streptococcus viridans* was definitely involved in only four instances. Trauma was directly responsible for the meningeal infection in four cases, and of these one showed a hemolytic streptococcus and another *Streptococcus viridans*. The therapy varied within wide limits.

We are indebted to Dr. Sidney Cohn for the opportunity of studying the following case of *Streptococcus viridans* meningitis.

REPORT OF CASE

A man, aged 22, white, was struck on the right side of the head, Jan. 6, 1934. Examination revealed a deep laceration of the scalp, but roentgenographic study of the skull showed no fracture. The patient was somewhat drowsy and complained of headache. The fluid obtained by lumbar puncture was opalescent, but no organism was obtained from it by culture (Fordham Hospital). Six days after the injury the patient was admitted to the Bronx Hospital with symptoms of increasing drowsiness, headache and soreness of the neck. The latter was moderately rigid. The leukocyte count was 20,000 per cubic millimeter, with 89 per cent mature polymorphonuclear neutrophils. The urine contained some albumin. The following day 20 cc of turbid spinal fluid was obtained which showed 5,000 cells per cubic millimeter, of which 96 per cent were polymorphonuclear cells. Sugar was present (166 mg per hundred cubic centimeters) and the total protein was 0.43 per cent. Smears of the centrifuged sediment showed cocci and a gram-positive bacillus suggestive of the anaerobic group. For this reason the senior author advised the use of gas gangrene serum. Accordingly, 5 cc of gas gangrene serum was administered intraspinally and the dose was repeated on the same day. The following day the patient appeared to be much improved. Further bacteriologic studies revealed *Streptococcus viridans* in pure culture in the fluid obtained by both taps. In view of the marked improvement, however, the gas gangrene serum was repeated in 5 cc doses on each of two subsequent days. The patient made a rapid convalescence and left the hospital one week later. The temperature curve showed peaks of 104.6 F. January 12, the day of admission, 104.2 F. January 13, 101.4 F. January 14, with a gradual remission thereafter to 99 F. by January 17. The pulse curve showed a corresponding decline from 130 to between 80 and 90.

The rapid transformation from an almost moribund state to one of complete recovery was of no little interest. Since no really specific therapy was utilized in affecting the disappearance of the organisms, an investigation was undertaken to determine the possible role played by the gas gangrene serum in the patient's recovery. We thought that this serum, if of high

opsonic power, would manifest its properties in the phagocytosis of the streptococcus by the numerous leukocytes present in the spinal fluid.

With this in mind, the immunologic study outlined in the accompanying table was made.

The table summarizes the results of two trials. The materials used were obtained as follows:

(a) Patient's serum. Taken when signs of recovery were evident.

(b) Gas gangrene serum A product of the Lederle Laboratories containing antibodies to the more common anaerobes i. e., *Clostridium perfringens*, *oedematiens*, *histolyticum* and *sordellii* and *Vibrio septique*

(c) Normal human serum

(d) *Streptococcus viridans*, spinal fluid Isolated from the first specimen of spinal fluid when the patient's condition was most critical

Fig. 1—Smear from mixture in tube 4 The two macrophages are loaded with streptococci

(e) *Streptococcus viridans*, throat A throat culture from the patient yielded this organism in pure culture

(f) Cells Obtained by intrapleural injection of a normal rabbit. One pleural cavity received 10 cc. of a 10 per cent solution of calcium gluconate. Into the other cavity was injected 6 cc. of sterile broth plus 4 cc. of the rabbit's own blood. Within forty-eight hours, both cavities yielded a purulent exudate which consisted mainly of polymorphonuclear leukocytes and mononuclear cells. A mixture of the two exudates was used for the test

The degree of phagocytosis was determined by staining smears from each tube with Wright's stain. The amount of growth was determined by streaking a loopful from each tube onto a blood plate. These cultures were made after two hours' and eighteen hours' incubation of the mixtures. The final reading represents an average of the two. In the column "growth on culture," the numbers refer to the number of colonies. The + sign was used in the second experiment because a heavier culture was tested and the colonies were too numerous to be counted, +++ signifies a heavy growth, while + signifies that only a few scattered colonies were visible after forty-eight hours' incubation

The results obtained confirm the hypothesis made previously, namely, the injected serum, by virtue of a property previously unknown, was distinctly inhibitive in its effect on the growth of these strains of *Streptococcus viridans*. We cannot postulate that the organism isolated from the throat was the same as the one found in the spinal fluid. The reactions of the two strains to the various serums were comparable, although the throat organism was more susceptible to phagocytosis. The mere presence of cells seemed sufficient to inhibit its growth (tube 11). In both cases the gas gangrene serum increased the degree of phagocytosis (tubes 4 and 12), as compared both with the patient's serum and with the normal serum control. With the organ-

ism, obtained from the spinal fluid, this increase was marked (tubes 1, 3 and 4)

If this "in vitro" test represents the reactions that took place within the spinal canal of the patient, it might be reasonably concluded that the fortuitous injection of the gas gangrene serum played a major role in the patient's recovery. The possibility of a spontaneous recovery, however, must also be borne in mind in view of Brieger's⁵ work. This investigator was able to reproduce experimental streptococcal meningitis in dogs and monkeys. Of fourteen infected but untreated dogs, four recovered spontaneously. In monkeys, the proportion of spontaneous recovery was one out of three.

However, because of the sudden change in the patient's condition which followed the injection of the gas gangrene serum and the experimental data we feel that the possible value of this therapy must be considered. On the other hand, we do not advocate the use of this serum as a specific for streptococcal meningitis. Other foreign serums might have acted similarly. The conclusions drawn from our study apply only to the case at hand.

The senior author saw, through the courtesy of Dr. A. Noah Schuller at the Jewish Memorial Hospital, another case of *Streptococcus viridans* meningitis which was secondary to the accidental puncture of the cribriform plate of the ethmoid during a nasal operation. The patient was treated with antimeningococcus serum until the organisms were identified by culture after which treatment was limited to repeated lumbar punctures. Recovery was complete in approximately three weeks.

Subsequent to the time this article was submitted for publication there was admitted to the Bronx Hospital,

April 10, a boy, aged 10 years, with typical meningitis of unknown etiology. *Streptococcus haemolyticus* was obtained from the spinal fluid on the day of admission and disappeared three days later, and the patient was discharged entirely well April 20.

EMBOLISM OF THE PERIPHERAL ARTERIES

RAYMOND W. BRUST, M.D.

Instructor in Medicine University of Pennsylvania School of Medicine
Assistant Physician to the Philadelphia General Hospital
(service of Dr. David Riesman)

PHILADELPHIA

Portis and Roth¹ recently reviewed the literature on embolectomy of the peripheral arteries and stated that only 131 cases had been reported. Four months earlier, however, Pearse² cited 296 cases which had been reported in the literature to July 1932.

All articles on this subject imply that the authors are in agreement with the commonly accepted opinion, that when gangrene results from the occlusion of large vessels, the resulting gangrene, without operation, is fatal.

Respect, however, has grown for the collateral circulation, especially in those portions of the body where end arteries have been said to exist. Case 1 is reported to demonstrate the fact that a fatal outcome is not always the result of a peripheral arterial embolism without embolectomy. This statement does not detract from the correctness of the conclusion of Key³ and others⁴ that in all threatening cases operation should be done. It merely offers hope for late inoperable cases and gives reason for the institution of general measures of palliative and sustaining treatment.

At the same time, the fact is recognized that the most recent authors⁵ feel that the collateral circulation plays a very important part in the restoration of circulation, even after embolectomy. Also the admission is noted that over half of the patients (52 per cent)² subjected to embolectomy died within a month following operation. It is pointed out that death in these cases was due to a primary systemic disease or to embolism of vital structures such as occurred in case 2.

CASE 1—Mrs. S. B., aged 70, white, seen at home, March 8, 1933, was in a condition of moderate congestive failure with

Fig. 1 (case 1)—The outlined area of scar corresponds to the extent of the preceding visible gangrene.

auricular fibrillation. The blood pressure was 200 systolic, 95 diastolic. She had been up and about doing housework until a few days before. She was given digitals and confined to her bed. Four days later a normal rhythm appeared to be established, when suddenly severe pain developed in the lower part of the left leg. It was not definitely localized but was described chiefly as being in the anterior and lateral portions of the lower two thirds. Posteriorly it was a little higher, although it was not felt in the popliteal space. Examination revealed that the left foot was definitely colder to the touch than the right. No dorsalis pedis pulse was palpated in the left foot, while a good one was palpated in the right foot. No pulse was obtainable in the lower left leg. Vascular sounds

were heard when the postero-internal aspect of the left thigh above the popliteal space was auscultated. A good popliteal pulse was felt and the sounds were heard in compression on the right side.

A diagnosis of popliteal embolism was made, and operation was recommended but refused. In a few days the pain was more definitely localized to the anterolateral aspect of the left leg and this area began to discolor. There was a recurrence of auricular fibrillation. The pain was intense and was relieved only by morphine.

By March 24 a typical gangrenous area was visible over the lower anterolateral aspect of the left leg and the whole calf was firm and tender. A heat cradle and alternate elevation and lowering of the leg brought indifferent results. There was no improvement in any of the vascular areas examined. Both legs continued to be moderately edematous. About the middle of April the pain was much diminished though still annoying, and the process seemed stationary, or even actually improved. Care had been exercised to provide sterile dressings over the gangrenous area to minimize infection and absorption of necrotic material.

Fig. 2 (case 1)—The arrow points to the contracted scarred area where the gangrene was maximal and corresponds to the widest area in figure 1.

April 28 an attack of acute pulmonary edema developed and the patient seemed to be moribund. However, she responded to morphine and atropine and a venesection of 425 cc. While she was quite weak for some time afterward, she gradually improved in every way. The superficial gangrenous area sloughed away and healing progressed slowly but continuously with only a few minor interruptions until the fall of 1933. At this time the last crust was removed and there was left only a shiny scarred area corresponding to the area indicated in figure 1. The edema had subsided greatly and the calf was soft and not tender. Figure 2 shows the appearance of the two legs on her seventy-first birthday, Jan. 26, 1934, less than a year after the onset. At the present time the color and temperature (to touch) are the same in the two legs. There is no discomfort and she gets about well enough without a crutch or cane to travel in an automobile. The auricular fibrillation has continued and there has been no return of either the popliteal or the dorsalis pedis pulse in the left leg. Her blood pressure at the time of the last picture was from 210 to 230 systolic and 90 diastolic.

CASE 2—Mrs. E. M., aged 71, white, admitted to the medical service of Dr. David Riesman at the Philadelphia General Hospital, July 4, 1933, suffering from moderate congestive failure, which had begun as a cough about three weeks previously and had gradually led to swelling of the ankles, dyspnea and palpitation.

Her general health had been good until three years before, when she began to notice a swelling of the neck. She became nervous and her eyes became prominent. She had some dysphagia and hoarseness.

The family history revealed several instances of hemiplegia and the fact that her mother had died of "galloping" consumption.

At physical examination she was acutely ill, with exophthalmos, which was more marked on the right side. The right pupil was smaller than the left and there was some lagging of the lid. There was shortness of breath, edema of the legs, cyanosis of the nails and distention of the vessels of the neck. A friction rub in the left side of the chest was thought to be due to pulmonary infarction. The heart was enlarged. There were no murmurs, but the rhythm was that of auricular fibrillation, confirmed by electrocardiography.

Three successful basal metabolic rate determinations were made. July 25 it was +33, August 16 it was +55, and August 31 it was +42.

5 Danzies, Max.

Her general condition improved very much in spite of the fact that the auricular fibrillation continued. Operation was considered inadvisable at the time, and she was discharged with instructions to return in a month after a course of compound solution of iodine and digitalis in maintenance dosage.

The patient returned, November 25, in a worse condition than she had evidenced at the time of her previous admission. There was marked anasarca, auricular fibrillation and thyrotoxic symptoms. The basal metabolic rate determination was +41.

The patient did fairly well on conservative treatment until October 10, when she seemed unusually pale and complained of severe pain in the left leg, which had begun earlier in the morning. She was seen by the intern and myself about 11 a m. The whole left leg was colder to touch than was the right. It was slightly swollen and had a bluish hue. There was no dorsalis pedis or popliteal pulse. The only pulsation in the left leg was that of the common femoral artery, palpated for a distance of about 2½ inches below Poupart's ligament.

The patient was seen in consultation shortly afterward by Dr. Patrick McCarthy of the surgical staff, who concurred in the diagnosis of femoral embolism. He advised immediate operation which was done under local 2 per cent procaine hydrochloride anesthesia at 2:30 p m.

An incision was made along the line of the left femoral artery. The vessel was exposed and its sheath incised. The location of the clot was visible and palpable at the bifurcation of the artery into the deep and superficial vessels.

An incision was made into the superficial femoral artery close to its origin and the obstruction was removed. It proved to be a "saddle" embolus involving both deep and superficial vessels. The vessel was closed and the wound was sutured without drainage.

There was some change in the color of the foot almost immediately, but there was some uncertainty as to whether the dorsalis pedis pulse could be palpated. However, the pulsation of the superficial femoral artery for a point some distance below its site of origin was good.

The next day the general condition was slightly improved and there was no evidence of gangrene. The auricular fibrillation continued.

The operative wound and the left leg improved steadily, but the patient's general condition was not good. Incontinence of urine and feces developed, October 13, and the patient was returned to the medical service, October 14, after removal of the sutures. There was good circulation in both legs.

When she returned to the medical ward, it was noted that the right side of the face was flattened and she appeared to have had a small cerebral vascular disturbance. Part of her drowsiness was evidently due to sedatives of the barbiturate group.

The general condition improved, though she continued to be incontinent. October 23, she was able to sit up, take medicine and answer questions intelligently. She had a good appetite. The patient maintained a fairly satisfactory condition, with occasional periods of mental confusion until November 7, when she became a little unruly and quite garrulous. She tried to get out of bed.

Death occurred suddenly, November 15, at 9:20 a m, without apparent pain or struggle. There was no autopsy.

SUMMARY

In two cases of peripheral arterial occlusion in elderly white women of similar ages, auricular fibrillation was present. In the first case the popliteal artery was occluded. A condition of gangrene resulted in the affected area. Termination of the gangrenous process and healing ensued. The patient is alive nearly a year later.

In the second case, complicated by thyrotoxic symptoms, the femoral artery was occluded. An embolectomy was done. The patient died nearly six weeks later after complete healing of the operative wound and restoration of circulation in the affected limb.

MORQUIO'S DISEASE

REPORT OF TWO CASES

DAVID B. DAVIS, M.D.

AND

FRED P. CURRIER, M.D.

GRAND RAPIDS, MICH.

In 1929, Morquio¹ of Montevideo reported a peculiar form of familial osseous dystrophy, occurring in four children of five in the same family. He was unable to find similar cases in the literature available to him.

Morquio stated that the children were apparently healthy and had developed normally during the first year. At the time that they began to walk, bony changes appeared, "sparing only the head and face and causing no pain or other suffering but functional troubles affecting especially motility and physical

Fig 1—Appearance of patients at ages of 6 and 9 showing scaphocephalic skulls, square chests and pot bellies. Note umbilical hernia in older boy.

trouble destroying the harmony of the body." He noted that the deformities were symmetrical, that the extremities were of normal length, though deformed, and that the thorax "was reduced in length and broadened." The results of a roentgen examination in each reported case of this peculiar form of dwarfism have been as characteristic as those described by Morquio. There has been demonstrated "osseous exuberance, for instance, in the vertebral column, the epiphyses of the elbows, the shoulders and the knees, or absence of ossification, for instance, in the wrists."

Since the publication of the description of the disease by Morquio there have appeared reports of the same condition by other authors.² None of the later

writers have described marked osseous changes in the skull or any eye disturbances, nor have they substantiated the presence of a low blood calcium, which was noted by Morquio. Although various glands have been mentioned, none of the authors have described the condition of the thymus gland.

As we have studies on the blood calcium, made three and one-half years apart, roentgenograms of the skulls

Fig 2—Scaphocephalic skull showing diastasis of coronal suture fused lambdoid sutures flattening of base and imperfectly developed anterior wall of sella

and the thymus glands, and also, in one instance, an encephalogram, we believe that our observations on this disease are worth recording.

REPORT OF CASES

Two brothers, R. C., aged 6 years, and K. C., aged 9 years, at the time of the original examination, Aug 15, 1930, were sent into the clinic with a diagnosis of cretinism. The father, aged 44, was living and well. The mother had died in 1925 following a pelvic operation. The oldest child, a girl, aged 14 years, died in 1915. Cretinism was given as the cause of death. Those who had seen her stated that her appearance was similar to that of the patients. A second daughter, aged 23 years, was feebleminded and was in an institution at the time the history was taken. The father stated that the mental disturbance had followed an attack of scarlet fever at the age of 8 years. A third daughter, aged 15 years, was normal except for the fact that she was slightly overweight.

When R. C. was 1 year old, it was noted that his head was becoming abnormally large, particularly in the anteroposterior diameter. Soon afterward, he could not completely flex the fingers on either hand, and he could not completely flex or extend the arms on the elbows. A similar condition was present in K. C.

Nothing was done for the children, although the deformities increased, until 1929, when they were seen by a physician who made a diagnosis of cretinism and placed them both on thyroid medication for three months. No improvement of their condition resulted.

In February 1930 they had been examined by the department of pediatrics at the University of Michigan.³ The results of examination of the two brothers were essentially similar, for

this reason only the results of the physical examination of R. C. will be given.

The head was found to be markedly enlarged. The occipitofrontal circumference was 55 cm (22 inches). The mouth was somewhat larger than normal. The hair was abundant but coarse. The nose was short and stubby, and there was a saddle-like depression of the bridge. The tonsils appeared to be hypertrophied. The tongue was larger than normal. The teeth were small. The chest was abnormal in shape. There was marked flaring at the costal margin, a prominent Harrison's groove, and some beading at the costochondral junction. The spleen was palpable two fingerbreadths below the costal margin. The liver was markedly enlarged and extended to the midpoint in the lower right quadrant of the abdomen. There was abdominal distention of the "pot belly" type. The circumference at a point 1 inch below the umbilicus was 60 cm (24 inches). The fingers were short and stubby. He had a typical spade or trident hand.

The blood chemistry of R. C. showed serum calcium, 112 mg (normal, from 9 to 11 mg per hundred cubic centimeters), inorganic phosphorus, 39 mg (normal, 37 mg per hundred cubic centimeters), and the fasting blood sugar was 85 mg (normal, from 90 to 120 mg per hundred cubic centimeters). The blood chemistry of K. C. showed serum calcium, 114 mg, inorganic phosphorus, 38 mg, and sugar, 81 mg. A dextrose tolerance test was performed on each patient and gave essentially normal results.

A diagnosis of bilateral buphthalmos was made on each of the patients, February 11, by the department of ophthalmology, and a bilateral iridectomy was advised for each. This operation was performed on K. C., March 25.

Fig 3—Lateral view of spine in January 1934, showing lack of normal curvatures, irregular vertebral bodies and some areas of exuberance, as in August 1930.

Roentgen studies of the hands, wrists, knees and elbows in both patients showed delayed epiphyseal development and distortion of the shaft of the phalanges, metacarpals and metapophyseal ends of the bones of the arm and forearm. The phalanges were thickened and their trabeculae were irregular and distorted. There were irregular areas of decreased density near the metaphyses. A flat projection of the skull showed a large cranial vault with a thin wall showing no increase in

³ Cowie D. M. Personal communication to the author with permission to use the observations made by the Department of Pediatrics University of Michigan.

digital markings The anterior wall of the sella was imperfectly developed The bridge of the nose was sunken

The description of one child is the same as that of the other, and therefore we shall record our notes only on the older child, K. C. The head, which seemed almost to sit on the shoulders, owing to the short neck, was scaphocephalic. Because of the shape of the head, the bridge of the nose appeared to sit back in the face and the lower part of the nose at the nares appeared to be broad and somewhat flattened. The jaw bone was larger than normal and out of proportion to the skull Figure 1 shows the squareness of the chest, which was due to an increase in the anteroposterior diameter He had a pot belly and an umbilical hernia, which protruded 2.5 cm The younger child had no hernia

In a relaxed standing position (fig 1), the backward position of the hips and the forward bend of the thighs was readily noted. The latter was due to the lack of ability to extend the legs on the thighs completely In fact, he could not completely extend the extremities at any of the joints, including the fingers The fingers could not be completely flexed

Nothing abnormal was noted about the thyroid, the lymphatic glands or the testes

There was no roentgenographic evidence of enlargement of the thymus The heart and lungs were normal

The intelligence seemed to be unimpaired. Vision was poor

The blood counts, the urinalyses and the Kahn tests were negative.

The roentgenologic studies were made by Dr T O Menees, and mention will be made of only those changes which are additions to the observations made by the University of Michigan Films of each head showed an unusually large cranium, with a thinning of the bones in the skull cap and dilated diploic channels The sagittal and lambdoid sutures were fused (fig 2) There was a diastasis of the coronal suture in the younger boy The spine was straight, showing a lack of normal curvatures, and it presented areas of exuberance (fig 3)

Because of the completely negative neurologic examinations and the presence of increased intracranial pressure, it was decided to make an encephalogram on the older boy This showed symmetrically enlarged lateral ventricles, with a slightly enlarged third ventricle, and a patchy distribution of air over the cortex

The patients were seen again in January 1934 Little change had taken place in the deformities (figs 4 and 5) The blindness had increased in both boys, but especially in the older, who was barely able to distinguish light and dark objects The optic disks in each case were extremely white, and there was an almost complete loss of all fine vessels Nothing abnormal was noted about the skin hair, nails or teeth No changes had appeared in the thyroid, testes or thymus (the latter checked by roentgen examination) The liver and spleen could not be palpated The blood calcium was 8.6 mg in the case of K. C, and 9.7 mg in that of R. C

Fig 4—Appearance of patients in January 1934 Both boys are trying to extend the arms and the fingers

The measurements for K. C, at the age of 13 years and R. C at the age of 9 years are given in the accompanying table

The results of the roentgen examinations were the same as those of 1930, except that in each case the skull showed an increase in the scaphocephalic deformity, and in the younger boy a ridge could be palpated along the line of the sagittal suture

The hands showed the same osseous deformities that were noted first at the University of Michigan in February 1930 The carpal bones presented the same changes (fig 6) as noted by Ruggles when he stated that "ossification begins in the distal row of carpal bones and they are always small and irregular in outline"

COMMENT

The history and physical examination of the one boy is virtually that of the other The changes that have taken place over a period of three and one-half years are well illustrated in the illustrations, particularly figures 1, 4 and 5

A review of the literature has convinced us that our cases are identical with those reported under the name of Morquio's disease In all reported cases of this type of osseous dystrophy there is a complete agreement as to the appearance of the body, but not as to the face and head Morquio stated that the face and head were not involved, Meyer and Brennemann noted that the head was large, Ruggles stated that the head was large, "eyes

wide spaced and the root of nose depressed", Barnett made the same statement as Ruggles No observer has noted any abnormalities on roentgen examination of the calvarium Our patients showed not only the large head, wide spacing of the eyes and the depressed bridge of the nose but, in addition, definite skull changes on roentgenologic examination

The skulls presented no suture lines in the plates made in August 1930 The shape of the heads was characteristic of scaphocephaly as described in pediatric textbooks The optic atrophy, with resulting blindness, is usually seen in the later stages of such a condition We did not therefore consider that the blindness was an unusual manifestation in our patients

Morquio stated that the oldest boy in the family he reported, although physically normal, was retarded mentally and had nocturnal hallucinations In the family that we have described, the oldest girl apparently had had the same osseous dystrophy as the boys,

Fig 5—Rigid midthoracic region of spine, and partially flexed knees and elbows as they appeared in January 1934

while the second child, also a girl, although physically normal, was an imbecile

Some effort has been made to determine whether blood chemistry changes may act as a causal factor in

Measurements of the Two Patients

Measurements for K. C. at the age of 13 years		Approximate Normal (Holt)	
Circumference of the head	22 ⁷ / ₈ inches	21	inches
Standing height	47 ¹ / ₂ inches	53 ⁷ / ₁₀	inches
Circumference of the chest	23 ³ / ₄ inches	27 ⁷ / ₁₀	inches
Weight	62 ² / ₁₀ pounds	88 ³ / ₁₀	pounds
Measurements for R. C. at the age of 9 years			
Circumference of the head	22	20 ⁸ / ₁₀	inches
Standing height	43	50 ¹ / ₁₀	inches
Circumference of the chest	22 ⁷ / ₈	27 ¹ / ₁₀	inches
Weight	49	60	pounds

production of the disease. Morquio is the only writer who has observed marked abnormality in the blood chemistry. He believed that the profound disturbance of osteogenesis could be explained by the low calcium content of the blood (4 and 5 mg, respectively, in the cases he studied). His theory has not been substantiated by the observations of Meyer and Brennemann, Ruggles or ourselves. The first readings in our cases, which were 112 mg for R. C. and 114 mg for K. C. in 1930, and the later ones of 97 mg for R. C. and 86 mg for K. C. in 1934 can be considered as normal.

Fig. 6—Right hand of older boy in January 1934 with no new centers of ossification since August 1930.

some of the characteristics of achondroplasia, there are certain changes that cannot be explained entirely on this basis. There are, as Morquio has said, "Rarefaction deformations, destructions, delays and absences." These changes affect the entire skeleton and are not limited chiefly to the epiphyses of the large and small bones of the extremities, as he stated. Other than achondroplasia, we know of no osseous dystrophy which this condition even resembles.

SUMMARY

1 So far as we are able to learn, the two cases of Morquio's disease, or generalized osseous dystrophy here described, are the only reported cases presenting extensive changes of the skull, which resulted in brain disturbance and optic atrophy.

2 No abnormality in the blood calcium was noted in either case in two observations made three and one-half years apart.

3 We believe that in this condition the osseous dystrophy is generalized, and the process not confined to the extremities, as in achondroplasia.

626 Medical Arts Building

A RATIONAL, NONSURGICAL TREATMENT FOR INTESTINAL FISTULAS

REPORT OF A CASE

FRANK R. GUIDO, MD

VISALIA, CALIF

The presence of an intestinal fistula, especially of the small intestine, whether it occurs spontaneously or is made surgically for the purpose of draining the bowel, is a most unwelcome condition and a trying ordeal for the patient and is frequently dangerous to life itself. To the surgeon it is frequently a most baffling complication to contend with, not only because of the difficulty to obtain a spontaneous closure but also because of the detrimental effects it has on the patient's organism as a whole as a result of the loss of the essential intestinal juices which, if not reabsorbed, cause marked changes in the body chemistry.

Much has been written in recent years concerning the toxemia of fistulas of the upper intestinal tract. Walters and Bollmann¹ have shown that the toxemia of acute duodenal fistula is due to the loss of pancreatic juice and the acid and chloride of the gastric juice through the fistulous opening. This toxemia is similar to that which occurs in high intestinal obstruction and is associated with a high concentration of blood urea, a decrease in blood chlorides and an alkalosis. The amount of fluid lost in these high fistulas is considerable and results in marked symptoms of dehydration.

Experimentally it can be shown that animals with an isolated loop of duodenum draining its contents to the outside die in from seven to eight days, although the continuity of the gastro-intestinal tract is restored by means of an anastomosis. In such cases blood studies reveal practically a normal chloride content but an enormous increase in blood urea. The importance of the reabsorption of intestinal juices was clearly shown by Wilkie in a case of obstruction in which an enterostomy was performed above the obstruction. Although this completely relieved the obstruction, the patient gradually grew worse until another enterostomy was made below the obstruction and the intestinal juices, which were being lost from the upper fistula, were reverted by means of a connecting tube into the lower fistula. The condition of the patient immediately improved.

Pancreatic juice is a powerful digestant of tissue and when it comes in contact with the tissues of the abdominal wall causes a marked destruction and irritation of the skin and underlying tissue, with large crater formation. It is therefore clear, from both clinical and experimental observation, that the leak from intestinal fistulas must be controlled and stopped for two reasons: (1) to prevent the loss of intestinal juices which are so essential to the body, and (2) to prevent the digestion of the abdominal wall, with the resultant slough and infection.

Fistulas of the upper intestinal tract are not infrequent and may occur as a result of operative procedures on the stomach or duodenum or spontaneously from a ruptured gastric or duodenal ulcer. The making of an enterostomy of either the small or large intestine is often a life-saving procedure and is a simple method

¹ Walters, Waltman and Bollmann. L. The Toxemia of Duodenal Fistula. J. A. M. A. 89: 1847-1853 (Nov. 26) 1927.

of decompressing a distended bowel. It is frequently performed as a preliminary to a more extensive operative procedure or in cases of acute mechanical obstruction, when, owing to the serious condition of the patient, a rapid and simple opening of the ileum or jejunum will often save a life.

It is my purpose in this paper not to dwell on the indication for jejunostomy or ileostomy, as they are well understood, but to emphasize a form of nonoperative therapy to be used in closing up these fistulas, which is simple, physiologically rational and attended with excellent results. It is well known that the operative attempt at the closure of such fistulas frequently results in failure and, owing to the presence of infection and loss of abdominal wall tissue, is fraught with much danger to the patient. Only rarely do these fistulas close spontaneously. In speaking of duodenal fistulas, Pannett² stated that they never heal spontaneously and if not closed prove fatal.

Any method of closure that is without risk to the patient and that is successful in a high percentage of cases will be welcome to the surgeon and to the desperately ill patient. The severity of intestinal fistulas varies directly as their distance from the pylorus—the closer to the pylorus, the more marked the toxemia and digestion of the abdominal wall. Although fistulas low down in the ileum produce very little toxemia, marked digestion of the abdominal wall occurs. Fistulas of the large bowel produce no toxemia and little or no abdominal wall digestion.

Potter³ of St. Joseph, Mo., was the first to make use of a physiochemical method to close these fistulas. He used tenth normal solution of hydrochloric acid to neutralize the alkalinity of the pancreatic juice, thus preventing tryptic activity, which is the active destructive and digesting agent in these cases. Tenth normal hydrochloric acid is the percentage of hydrochloric acid that is normally present in the gastric juice and therefore should be the ideal strength to use. Together with the acid, Potter also employed sterile beef extract and olive oil, which would act as a pabulum for the excess of pancreatic juice and bile that was not neutralized by the hydrochloric acid. At that time Potter reported one case of duodenal fistula which occurred following operation on a perforated duodenal ulcer and which was unsuccessfully treated by surgery. Within a few weeks after the use of the hydrochloric acid treatment the fistula was entirely closed and the wound healed. In 1929 Potter⁴ reported eight more cases of duodenal and intestinal fistulas, which were quickly healed by the use of the hydrochloric acid treatment.

FORMER METHODS OF TREATMENT

Operative intervention is usually attempted to close these fistulas and it is readily seen that their success is most limited. In fistulas close to the pylorus the general condition of the patient is usually precarious, the tissues are most friable, infection is present and accurate surgical closure is most difficult to obtain and frequently results in the reforming of the fistula. Also, patients frequently die of toxemia, exhaustion, emaciation or dehydration before an attempt at surgical closure can be made. In the treatment of duodenal fistula,

Cameron⁵ used a continuous suction apparatus in an effort to prevent the digestive juices from coming in contact with the tissues of the abdominal wall. Although theoretically this is a logical method of attack, nevertheless practically many difficulties are encountered, and it is most difficult to keep the wound dry and free from the digestive fluids. Constant attendance is required at all times. Co-Tui,⁶ in an experimental study on dogs, used kaolin powder around the mouth of the fistula in order to remove the enzyme trypsin. The powder must be changed as soon as it becomes saturated, the number of changes depending on the amount of discharge. I am not familiar with this method of treatment.

PROPOSED METHOD OF TREATMENT

This is the method suggested by Potter and consists of the application of tenth normal hydrochloric acid. The hydrochloric acid solution is used as a wet dressing around the wound and a plug of gauze saturated with the acid solution is put into the crater of the fistula. No petrolatum or other ointment is used around the wound. The dressings are changed as often as they become saturated, and it is most important to have an excess of acid present to neutralize the alkalinity of the wound discharge completely. In a high fistula the dressings must be changed frequently because of the high alkalinity and large amount of the discharge and because the discharge is so liquid. At the time of each dressing the fluid in the crater of the wound is gently aspirated, thus keeping it as dry as possible at all times. In order to render the fecal content more solid, the patient is placed on a constipating diet, from 4 to 6 ounces (120 to 180 cc) of boiled skim milk being given every few hours. Opium may be given in the form of either the tincture or the powder. The amount of other fluids by mouth is limited to 1,000 cc a day. The solidification of the fecal content considerably lessens the irritation. In the case of a duodenal fistula, the intestinal discharge is water-like, and it is impossible to solidify it by any known means. Together with the hydrochloric acid Potter used sterile beef broth, which acts as a pabulum for the trypsin. However, in fistulas of the lower part of the ileum it is possible to control tryptic activity with the use of hydrochloric acid alone, as I was able to do in the case here reported. When tryptic activity is most pronounced, as in the upper part of the intestine, it may be necessary to include the sterile beef broth with the hydrochloric acid, since the pancreatic juice is present in such large quantities that complete neutralization with hydrochloric acid alone is difficult to secure.

REPORT OF CASE

The following is a report of a fistula of the ileum made surgically for the purpose of relieving tension and draining the bowel in a case of paralytic ileus following appendectomy.

A. H., a man, aged 57, with a negative family history, seen by me on the morning of Sept. 16, 1933, stated that he had never had a serious illness, although he had been having some backache on the right side for the past year, which he attributed to an injury of the back. He had also suffered a number of mild attacks of abdominal pain, which would last

only a few hours and for which he did not seek any medical attention. The present attack began ten hours before with severe cramplike pain in the abdomen. The temperature was 100 F, the pulse 90 per minute, the respiration rate 16 per minute.

General physical examination was negative except for the abdomen, which showed marked tenderness over the entire right lower quadrant and right lumbar region. There was severe pain on any attempt to extend the right thigh at the hip. Laboratory examination showed 16,500 white blood cells per cubic millimeter, with 85 per cent neutrophils. The urine was normal. A diagnosis of acute appendicitis was made and immediate operation was decided on.

Under spinal anesthesia the abdomen was opened through a McBurney incision. A small amount of free seropurulent fluid was present in the peritoneal cavity. The appendix was perforated at the distal end and a small fecalith was free in the peritoneal cavity. The cecum and appendix were firmly bound down to the posterior parietal peritoneum, and there was extensive gangrene of the mesenteric lumen. Appendectomy was performed in the usual manner and a cigaret drain was placed at the base of the cecum. The abdomen was closed in the usual manner.

At the time of operation it was noted that the small intestine was somewhat dilated. Although nothing was given by mouth and fluids were given intravenously, distention gradually increased. There was no evidence of any peristalsis, and signs of paralytic ileus became more marked. The usual palliative measures were of no avail and on the fourth postoperative day an ileostomy was performed under local infiltration anesthesia. A left muscle-splitting incision was used and a catheter was sewed into a loop of ileum with the Witzel method. There was immediate evacuation of much foul and toxic material through the ileostomy opening. Within two days gas began to pass both by rectum and through the ileostomy tube, and feeding of dextrose and sodium chloride was started through the tube. The general condition of the patient gradually improved and the enterostomy tube was removed on the seventh day. Within three weeks the appendectomy wound, which had had a considerable amount of fecal drainage was entirely closed, but as bowel tonus increased the thin, watery fecal drainage from the enterostomy wound became so profuse that dressings had to be changed every two hours. The skin became raw and irritated and a large crater formed, which showed no signs of healing. The discharge was strongly alkaline.

October 22, about four and one-half weeks after the original ileostomy was performed, the Potter method of treatment for closure of the fistula was started. Gauze soaked with tenth normal hydrochloric acid was applied to the wound in the form of wet dressings, and a plug of gauze was inserted into the crater. Dressings were changed as often as they became saturated with bowel secretion. Boiled skim milk and tincture of opium were given in an attempt to harden the fecal contents. November 5, i. e., fifteen days after the beginning of treatment with hydrochloric acid, the fistula was entirely closed and the wound all healed.

COMMENT

In this case, within a period of about two weeks it was possible to close a fistula of the ileum, which was discharging very alkaline irritating fecal matter, by the use of wet dressings of tenth normal hydrochloric acid. The fistula showed no signs of closing spontaneously, in fact, the digestion of the abdominal wall was becoming more pronounced every day. The method is based on physiologic principles, is without danger to the patient and is highly successful. The method should be given a fair trial in all cases of intestinal fistula before any attempt at operative intervention.

CONCLUSIONS

- 1 The persistence of intestinal fistulas is due to the proteolytic action of trypsin.
- 2 Upper intestinal fistulas heal spontaneously only on very rare occasions.

3 High intestinal fistulas, per se, result in marked changes in the blood chemistry due to fluid losses and chloride depletion.

4 The use of dressings soaked in tenth normal hydrochloric acid will neutralize the alkalinity of the intestinal juices and thus inhibit tryptic activity, resulting in closure of the fistula.

5 The risk and poor results of operative intervention is eliminated by the use of tenth normal hydrochloric acid.

6 The Potter method of treatment of intestinal fistulas is based on physiologic principles, it is without danger and should be tried in all cases.

Clinical Notes, Suggestions and New Instruments

ONYCHIA DUE TO CHRONIC HYPOVITAMINOSIS

CLEVELAND WHITE M.D. CHICAGO

Clinical pictures of unmistakable signs and symptoms due to hypovitaminosis or avitaminosis are well known. In a recent editorial¹ of THE JOURNAL are emphasized the remarks of McLester² that chronic vitamin deficiency may produce vague borderline or subclinical disorders. While many syndromes are being attributed to lack of vitamins at the present time, seven cases of definite nail deformities have been observed in the past two years which are believed to have been due to chronic hypovitaminosis, especially B and D.

CLINICAL MANIFESTATIONS

The earliest manifestations are irregular, longitudinal ridging with short transverse, semipunctate depressions. This was first observed in a woman aged 38, who had restricted her diet too severely in controlling the symptoms of another disease. The six other patients were all women who had dieted for several years because of a marked tendency to become obese. Ages ranged from 35 to 50. All had abstained from butter and all "fattening" foods. The most pronounced case showed marked dystrophy of the terminal portion of the nail plates. All gradations of nail changes occurred between these two types. All nails were involved and there were no subjective symptoms. There were no other dermatologic changes. Two showed lowered metabolic rates of -20 and -14, but administration of thyroid extract by mouth did not effect any improvement in the nails, whereas giving foods and medicaments containing vitamins B and D did. The nails had shown changes for about six months to six years.

DIFFERENTIAL DIAGNOSIS

In the more pronounced cases, onychomycosis (ringworm of the nails) and psoriasis must be ruled out. In a series of seventy-four cases of onychomycosis, the absolute diagnosis can be made only with the finding of fungi either microscopically or culturally, because the clinical picture varies from a mild scaly nail thickening to almost total destruction of nails with a remaining powdery residue. Psoriasis of the nails can occur alone but is usually associated with typical cutaneous changes of that disorder. The nail manifestations of psoriasis are being discussed in another paper.³

COMMENT

That vitamin deficiency can produce dermatologic syndromes is well illustrated in a recent paper by Loewenthal.⁴ He noted a papulofollicular dermatosis associated with dryness of the skin. Hutter and Middleton⁵ have noted the tongue changes in a number of cases due to vitamin B deficiency. Nail changes have been noted in the various anemias by many writers, and numerous causes have been mentioned in such cases.

No animal experimental work confirms these clinical impressions, and Steenbock⁶ states that he has not regularly noted such nail changes in his animal studies. No nails were removed for histologic study, as patients would not permit it.

The treatment consisted of large doses of haliver oil with vosterol and foods containing vitamins B₂ and D. The nails of six patients became essentially normal, while the seventh is vastly improved. The last patient had had nail changes for six years and the nails had become disintegrated, showing only about one eighth of normal nail present when first observed. Six had had local therapy in other hands with no improvement.

SUMMARY

Nail changes varying from slight transverse depressions with longitudinal ridging to marked dystrophy were noted in seven patients.

Deficiency of vitamins B₂ and D due to restricted diet was believed to be the etiologic factor.

All the nails have responded either by a cure or by marked improvement to the administration of these vitamins or foods containing these vitamins.

MASSIVE SKIN GANGRENE COMPLICATING CHICKENPOX

T. M. WATSON, M.D., GREENVILLE, N. C.

This case is reported because massive gangrene of the skin is an unusual complication of chickenpox.

REPORT OF CASE

H. C. Jr., a schoolboy, aged 6 years, had had a normal birth and infancy. He had never had any severe illness. There had been frequent colds before the tonsils and adenoids had been removed two years before. Since that time he had been perfectly well except for a mild case of measles four months previously. He was doing well in school.

There was an epidemic of chickenpox in the schools at the time of the onset of illness. Five days before he entered the hospital a low grade fever developed and the boy complained of pains in the joints. Two days later vesicles characteristic of chickenpox appeared on the skin. There were few of them and all indications pointed to a mild attack. On the fourth day of the illness the patient became very restless, the temperature went to 104 F, the pulse to 180, and the boy had a convulsion. Examination at this time showed no evidence of infection except the chickenpox lesions on the skin and an elevated tumor surrounding a small lesion on the skin. This was in the right axillary line at the level of the ninth rib. It was one-half inch (1.27 cm) in diameter and was indurated and tender. There was no discoloration of the skin.

The white blood cell count was 16,000 with polymorphonuclears, 62 per cent; small lymphocytes, 34 per cent; eosinophils, 2 per cent; transitionals, 2 per cent. The urine was normal except for a fairly heavy trace of albumin. The Wassermann reaction was negative. The tuberculin test was negative. The spinal fluid, the bleeding time and the coagulation time were normal.

Four hours after examination the skin over the tumor became discolored, apparently from intracutaneous hemorrhage, and twelve hours later a section of skin an inch (2.5 cm) in diameter, over and surrounding the tumor, became gangrenous and showed that it was going to slough. For an inch around the sloughing area the skin showed ecchymosis. The intra-

cutaneous hemorrhage, followed in a few hours by gangrene, spread so rapidly that at the end of twenty-four hours the gangrenous area was 6 inches (15 cm) wide and extended from just below the axilla to the crest of the ilium. The patient was profoundly toxic, nauseated and delirious, and the temperature ranged from 104 to 107 F. The skin was dry, the eyes were sunken, and the expression was pinched.

The fifth day after the onset, he was taken to the hospital. One thousand cubic centimeters of Hartman's solution¹ was given intraperitoneally and 400 cc. of 10 per cent solution of dextrose intravenously. This did not improve the general condition much. The symptoms of toxemia continued, and the gangrene, preceded by intracutaneous hemorrhage, continued to spread.

Eight hours after admission to the hospital a transfusion of 500 cc of blood was given. The effect of the blood was rapid and marked. The symptoms of shock cleared promptly. After three hours the temperature was 102 F, and the pulse rate had come down from 180 to 120 per minute. The patient was quiet and rational. The vomiting was checked and he began taking and retaining fluids. It was most noticeable that neither the hemorrhage in the skin nor the gangrene advanced any further after the blood was given.

For two days after the transfusion, progress was satisfactory, then there was a return of the toxic symptoms, with a temperature of 104 and a pulse of 170. There was rigidity of the neck and the Kernig sign was positive. Anhydremia

Skin lesion thirty days after onset, showing first patch of grafts

was evident, in spite of the fact that the patient was getting a fair amount of fluid by mouth and was getting from 1,500 to 2,000 cc parenterally each day. There was no extension of the skin lesion. The slough had broken loose from the surrounding skin and left a punched out border, and the surrounding skin was undermined for about half an inch. The dead skin was contracting toward the center and there was an enormous exudation of yellowish fluid from the raw surface. Examination of the chest revealed bronchopneumonia in the lower lobe of the right lung.

A second transfusion was given from another donor. Improvement was not so marked as was the case after the first transfusion, but the general condition improved somewhat. The signs of meningeal irritation cleared after eight hours and there was much less fluid loss from the skin lesion. For ten days after the second flare up the course was that of a severe bronchopneumonia, then the lung signs and the fever gradually cleared. The temperature reached normal on the eleventh day after the second transfusion was given. For two weeks the patient did not lose ground, but he made very little progress. His appetite was poor and great difficulty was experienced in administering enough food and fluids. A third transfusion was given from the original donor. After this, the climb to recovery was steady.

1. The formula of Hartman's solution of physiological buffer salts (Lilly) is as follows: sodium lactate (lactic acid 85 per cent) 0.6 cc, sodium chloride 1.5 Gm, potassium chloride 0.1 Gm, calcium chloride 0.05 Gm, distilled water sufficient to make 10 cc. This stock solution is to be diluted twenty five times before using.

5. Hutter, A. M. and Middleton, W. S. with the collaboration of Steenbock, Harry. Vitamin B Deficiency and the Atrophic Tongue. J. A. M. A. 101: 1305 (Oct. 21) 1933.

6. Steenbock, Harry. Personal communication to the author.

The skin lesion was treated by Drs J L Winstead and W I Wooten of the Pitt Community Hospital. Wet boric acid dressings were kept on the area almost continuously until the sloughing skin and subcutaneous tissue had cleared away, leaving a healthy granulating surface. Three weeks after admission to the hospital autoplasmic grafting was started, as shown in the accompanying illustration. A small patch of tiny pinch grafts was put on every three or four days until the surface was covered. Practically every graft taken from the patient grew.

Isoplastic pinch grafts from the mother were tried, about 4 inches square being covered by her skin. These looked perfect for eight days and then the whole area covered by the mother's skin swelled up about half an inch above the level of the surrounding skin. There was vomiting, diarrhea and generalized urticaria, and the face was swollen markedly. This protein reaction continued for forty-eight hours and then subsided. As the swelling cleared from the isoplastic grafts they dried up and fell off while those taken from the patient on the same day grew.

Besides the lesion described, there were fifteen other vesicles which crusted over and spread out to about 25 mm. When these crusts were removed, a superficial ulcerated area was seen. They did not involve the entire thickness of the skin, as was the case in the major lesion.

The patient was discharged from the hospital in good condition sixty-four days after the onset of his illness. At the time of discharge the hemoglobin registered 110 per cent.

CONCLUSION

Frequent blood transfusion and large amounts of parenteral fluid are of decided value in the treatment of disseminated gangrene complicating chickenpox.

THE EYE DROPPER

T J DIMITRI, M.D., NEW ORLEANS

The construction of the eye dropper is such that the contained fluid comes in contact with its rubber bulb or cap, and this not alone at a time following a change in its position from the vertical to the horizontal but also when the rubber bulb has a greater pull than is necessary to fill merely a part of the glass tubing, and, as a result of this, the contents act on the rubber bulb and produce a change that becomes a source

Fig 1—Eye dropper made of glass. At the bulb end the lumen of the tubing is reduced to capillary size. The outer dimensions remain in conformity to the rest of the tube.

of danger when dropped onto or into sensitive parts of the body. An applicable example is the danger at the time of a cataract extraction when an open wound is exposed to these products of rubber dissolution.

This danger is so obviously true concerning the harm that can come from the disintegrated rubber in an open wound that it was thought proper to devise an eye dropper that would prevent the fluid coming in contact with the rubber bulb and

Fig 2—One or more capillary tubings are inserted into a glass tubing and made enduring by the application of heat. These smaller tubings prevent the fluid from coming in contact with the rubber bulb.

in doing so, remove a hazard that is commonly unrecognized by the ophthalmologist and is detracting from his endeavors in the prevention of blindness. Therefore, I submit an eye dropper or droppers that will minimize and probably entirely remove this danger, and without greatly increasing the cost of construction.

The tubing part is made of any length, of the same material, namely glass, the smaller end is unaltered and the rubber bulb remains the same. The difference in the type offered as compared to the old is featured at the rubber bulb end in which

the lumen is reduced to a capillary size, this being done without change in the outer dimensions of the tubing. At the time of its construction, when a part of the tubular glass is held in the flame and about to become a solid unit at the heated part, a small amount of air is blown from one end of the tube while yet in the flame. When the tube is removed from the flame, the diameter of the lumen of the part that was in the flame is governed by the amount or force of air blown through the tube. (The finished product is shown in figure 1.)

This dropper is most satisfactory and answers well the requirements, yet others may desire it to be made even more certain in action so as to avoid the vacuum lost, for the objec-

Fig 3—A modification of Stern's container for eye medication.

tion may be raised that the liquid can be made to enter the rubber after repeated pressure on the bulb and if the bulb happens not to fit perfectly to the tube, either because of over size or of a decrement in its elasticity. For this reason, I produced dropper 2 which is shown in figure 2. It is made by inserting in the glass tubing a division having the appearance of the smaller end of a dropper in a glass tubing of larger size and the large tubing retains the same pointed end as in the old type. This is accomplished by first making the tips. These are inserted into a glass tubing of larger size and made enduring by applying heat. Because of these divisions, the fluid cannot come in contact with the bulb, and the rubber, as a consequence, retains its physical and chemical qualities much longer.

The third is a modification of Stern's container and eye dropper. This was also suggested because of contact of the liquids with the rubber caps. The objection can be overcome by utilizing the feature spoken of in dropper 2 and the reduction in size of the smaller end. This modification is shown in figure 3.

These types of eye droppers have been constructed for me by Mr G P Seiler of this city.

Teresita Apartments, St Charles at Napoleon Avenue

A SIMPLE METHOD OF TREATING COMPLETE SEVERANCE OF THE URETHRA COMPLICATING FRACTURE OF THE PELVIS

JOHN K ORMOND, M.D., AND ROBERT M COTHRAN, M.D., DETROIT

Fracture of the pelvis is now a fairly common occurrence and is frequently complicated by rupture of the bladder or urethra and, at times, by complete severance of the bladder from the urethra. When this occurs the tear takes place at the point of exit of the urethra from the prostate gland itself with the prostatic urethra remaining attached to the bladder. In such cases immediate repair is urgently indicated, for if the repair is left till later the scar tissue and distortion resulting from the effects of the original trauma render a plastic operation difficult of performance and a stricture following the repair an almost inevitable sequel. For some years we have had under our care one such patient on whom Dr Hugh Young had operated eleven years after his accident obtaining a splendid result. The continuity of the urethra had been restored, allowing the cystostomy of eleven years' duration to close. But it is still necessary for him to have the urethra dilated from time to time.

In case the repair is made immediately and the continuity of the urethra restored before scar tissue has formed, there is apt to be much less trouble later. Unfortunately, these patients often suffer from shock and any lengthy procedure is contraindicated. Drainage of the bladder of course is necessary. In some cases good results in restoring urethral continuity have been obtained by the use of an indwelling catheter introduced at the time of operation.

In a recent case we made use of a simple method for restoring the continuity of the urethra which we believe has

From the Division of Urology, Henry Ford Hospital

definite advantages over the indwelling catheter in effectiveness and is just as quickly and easily applicable

REPORT OF CASE

A man, aged 47, was brought to the hospital in the early morning, following an automobile accident. He was found to have a fractured pelvis. There were no signs of rupture of the bladder or of urinary extravasation, but he was unable to void. In the afternoon, since he had not voided and since there was dullness rising above the symphysis a catheter was passed, it being necessary to use a filiform and follower catheter on account of an old stricture in the perineal urethra.

Fig 1—Uninflated bag in place but not drawn down

A small amount of blood was obtained but no urine. Suprapubic operation was then done. The bladder was found distended with urine, and it and the prostate were completely torn away from the urethra, there being a large amount of clot and liquid blood in the subvesical space, into which the catheter had entered. Speed was essential on account of the patient's condition. Moreover, because of the pelvic fracture, it did not seem to us advisable to place him in the lithotomy position, which would have been necessary for suture of the urethra through the perineal approach. Accordingly, a small sound was passed through the urethra till the end was felt in the subvesical space, through the opened bladder a finger was passed through the prostatic urethra into the subvesical space, meeting the end of the sound and guiding it into the bladder. Then the urethral tube of a Picher bag was threaded onto the end of the sound and drawn out of the urethra. After the

Fig 2—Bag inflated and drawn down. The blood clot has been removed

bag was distended with water the neck of the bladder could be drawn down till it seemed to us that the lower pole of the prostate was in apposition to the torn end of the urethra, at the triangular ligament. This approximation was maintained by strapping the tube to the patient's thigh under just enough tension to hold the bladder neck snugly in place. It was left in this way for two weeks. The water was then allowed to escape from the bag, and the bag was drawn up out of the wound and cut off from the urethral tube, which was left in place as an indwelling catheter for a few days longer, and then withdrawn. As the suprapubic wound closed the patient has been able to void freely and with perfect control. We have as yet no information concerning his sexual

powers but feel sure that they stand a better chance of remaining intact than if an extensive perineal operation had been performed. He will, of course, be watched carefully for strictures, and the urethra will be dilated from time to time for the old stricture requires this whether the scar of the healed rupture contracts or not.

The accompanying diagrams show the position of the bag and illustrate its use. The bladder is shown as if it were distended, in order to bring out the position of the bag more clearly. Obviously, with a suprapubic opening the bladder would in actual fact be collapsed.

The bag is commonly employed to produce hemostasis following suprapubic prostatectomy, and a few cases of temporary weakness of the external sphincter after its use have been reported. Being conical and lying in the prostatic bed, it must have been drawn partly into the membranous urethra, dilating it and causing ischemia. In a case such as we have described, this need not be feared, for two reasons. First, only moderate tension is necessary. Second, the bag lies wholly within the bladder and will not be drawn into the membranous urethra.

OSTEOMYELITIS OF THE RIB COMPLICATED BY EMPYEMA IN AN INFANT

RECOVERY OF BOTH PROCESSES FOLLOWING ASPIRATION OF EMPYEMA

I J WOLF M D PATERSON N J AND H B RING M D
PASSAIC N J

This report is prompted by the complete recovery occurring in a case of osteomyelitis of the rib complicated by an empyema in an infant, in which conservative treatment was followed.

REPORT OF CASE

History—Thomas P., aged 6 months, was admitted to the Barnert Hospital, Dec 29, 1933. One month before he had caught cold, and a left otitis media developed a week later. A myringotomy was performed and the ear drained for three weeks. About a week after the ear was opened, an indurated swelling about 2 inches in diameter appeared on the right side of the back at the angle of the scapula. This seemed to recede somewhat and a few days later a much smaller swelling was noticed on the lower part of the right forearm. The infant's past history was irrelevant.

Physical Examination—The temperature on admission was normal. During the examination the infant cried constantly but more so when the swellings on the back and forearm were manipulated. The left ear was draining slightly. The chest was clear, the abdomen was normal. The knee jerks were hyperactive the left more so than the right. The right superficial abdominal reflex was not elicited. On the dorsum of the right forearm overlying the ulna at the junction of the lower third and the upper two thirds, a slightly reddened, fluctuant swelling was found about 24 mm in circumference. A larger fluctuant swelling about the circumference of an orange was seen on the right side of the back at the angle of the scapula. These gave the impression of abscesses.

Progress—The next day the infant was much less irritable. The evening temperature of the previous day was 104 F. The abscess on the back had completely disappeared, and the swelling on the right forearm was considerably smaller. When the chest was examined, unmistakable signs of fluid were found on the right side. This was striking, as the chest had been clear the day before. The respiratory rate was 40. A roentgenogram of the chest revealed a homogeneous opacity obliterating the right costophrenic and cardiophrenic angles and the axillary portion of the right lung, the heart was displaced to the left. In addition there was a considerable destruction of the right ninth rib near its angle. A roentgenogram of the wrist showed a stripping of the periosteum of the right ulna in its lower half.

December 31 a thoracentesis was performed in the right posterior axillary line, but only a few drops of purulent hemorrhagic fluid were obtained.

January 1 the respiratory rate was 70, the infant was cyanotic. The temperature rose to 105 F the evening of the

From the pediatric service of the Barnert Hospital Paterson N J

previous day. A second roentgenogram showed a homogeneous opacity of the entire right chest due to effusion. A blood culture taken on this day proved negative. A blood count revealed 3,800,000 red cells, 72,000 white blood cells, with 86 per cent polymorphonuclears, 2 per cent eosinophils and 12 per cent lymphocytes. The urine showed amorphous urates and an occasional epithelial and red blood cell. The infant's general condition was poor. He was placed in an oxygen tent and was kept stimulated.

January 3, 40 cc of frank pus was aspirated from the right chest. On smear there were polymorphonuclear leukocytes and streptococci, on culture, a pure strain of hemolytic streptococci. Following the tap the infant's condition was markedly improved. The temperature and respiratory curves fell to normal and an uneventful recovery followed. January 5, a thoracentesis proved unsuccessful. A roentgenogram, January 8, revealed considerably less fluid in the right side of the chest than on January 1, but more than on December 30. January 23, the fluid in the right chest was absorbed. The osteomyelitis of the rib showed healing. The wrist appeared unchanged and examination of the part showed induration.

March 3, the patient visited the clinic. He had gained 5 pounds (2.3 Kg). Physical examination of the chest and wrist were negative. Roentgen examination also was negative. A blood Wassermann test was negative.

COMMENT

An osteomyelitis of the right ninth rib and the right ulna complicated a purulent otitis media in an infant aged 9 months. An abscess of the soft parts overlying the osteomyelitis of the rib subsequently ruptured into the pleural cavity. Whereas the chest had been clear the previous day, the right side was found to be filled with fluid subsequent to the disappearance of the abscess on the posterior chest wall. Roentgenographic examination corroborated this and revealed a well advanced osteomyelitis of the right ninth rib. The child became very toxic, dyspneic and cyanotic. His condition was very poor for several days. The case was treated as an ordinary empyema complicating a pneumonia. Tapping was resorted to, to relieve the fluid accumulation and to give the mediastinum an opportunity to become fixed. One aspiration of 40 cc of pus was sufficient to enable the infant to resorb the remaining fluid, making thoracotomy unnecessary. Resection of the osteomyelitic portion of the rib was also unnecessary as it healed of its own accord, as did the process in the right ulna.

OCCURRENCE OF DIABETIC GANGRENE IN AN UNUSUAL LOCATION

C W W ELKIN M D PITTSBURGH

This case of diabetes mellitus is reported because of the unusual location of the complicating gangrene and infection.

Mrs. S. L., aged 42, a married Jewish woman, seen in October 1931, gave a history of having had diabetes mellitus for six years, without any dietary or insulin treatment. After a short period of supervision of treatment, the patient went through a pelvic operation quite satisfactorily in November 1931, but refused to follow dietary instructions or take insulin. She was not seen again until Nov. 28, 1933, when she was found in a stuporous condition with "air hunger" and "acetone breath." Over the lower part of each labium majus was a large gangrenous area, from one of which (the right) was draining considerable pus. In addition there was a gangrenous area over each ischial region, with considerable sloughing of tissue on the right side. Between the labial and ischial areas involved there was practically continuous swelling, redness and induration, and on the right side an apparent subcutaneous sinus connecting the two areas. Through this sinus pus could be expressed. Marked glycosuria was present, the blood sugar being 0.240.

The patient refused hospitalization. Treatment with diet, insulin and local care of the infected gangrenous areas resulted in marked rapid improvement, and Feb. 2, 1934, the wounds were healed and the diabetes well under control.

121 University Place

POISONING BY CAMPHOR

WILLIAM R. KLINGENSMITH M.D. AMARILLO, TEXAS

Camphor poisoning is uncommon. Cases with a fatal termination have been reported.¹ Recovery following the ingestion of 450 grains (30 Gm.), and death from the ingestion of 18 grains (1.2 Gm.) is reported. Benz,² Haft,³ Blair¹ and Cottrell⁴ report recovery after the ingestion of varying amounts of camphor in oil. Osborne⁵ says "It is difficult to cause poisoning in the human unless the amount is excessive, then respiratory depression and convulsions might be caused." Stevens⁶ says "Toxic doses first produce excitement, nausea and vomiting, delirium and epileptiform convulsions, then coma and collapse." Neither text states that the outcome may be fatal. Recovery without sequelae or complications seems to be the rule, however, in Cottrell's⁴ case very definite evidence of cerebral irritation continued for several days. Of the later reports in the literature, camphor in oil is universally the preparation ingested. The earlier reports in the literature^{1,2} indicate that a solution of camphor in alcohol may have been responsible for the poisoning in many instances. Probably alcoholic solutions are more rapidly absorbed, thus accounting for the incidence of more fatalities in the earlier reports. Clinical manifestations vary. Predominant among the cases reviewed are the following symptoms: convulsions, epileptiform in character, coma, and spasticity of musculature. Convulsions are severe and usually unattended by loss of sphincter control. The pulse rate, blood pressure and respiratory rate may be normal or increased. There is no criterion on which to base the diagnosis except the history or the detection of the drug in the stomach contents.

REPORT OF CASE

Miss N. T., aged 22, admitted to the Northwest Texas Hospital, Nov. 27, 1933, took by mistake, thirty minutes prior to admission 2 ounces (60 cc.) of a 20 per cent solution of camphor in oil (180 grains, 12 Gm.). About twenty minutes later she became nauseated and vomited recently eaten food containing unmistakable evidence of camphor. The nausea was preceded by a slight burning in the epigastrium, otherwise there was no discomfort. Immediately following emesis she had a violent convulsion, epileptiform in character, unattended by loss of sphincter control. A few minutes later when she was pale, appeared terrorized and was unable to talk. Her hands and arms were in constant purposeless motion. An immediate examination revealed a general spasticity of the skeletal muscles and a slight increase in the patellar reflexes. The eyes responded sluggishly to light, the pupils being of equal size but irregular in outline. The blood pressure was 140 systolic, 90 diastolic, the pulse was 140.

At about the time these observations had been made she had the second violent convulsion, similar to the first. She was immediately given $\frac{1}{100}$ grain (0.0006 Gm.) of scopolamine hydrobromide subcutaneously and 0.5 Gm. of sodium amylal intravenously. She responded at once, became completely relaxed and went into a profound sleep. The patient's stomach was then lavaged thoroughly with sodium bicarbonate solution. Two ounces of magnesium sulphate, saturated solution, was given through a lavage tube. Hypodermoclyses with 500 cc. of physiologic solution of sodium chloride completed the immediate treatment. About five hours later when she awoke there was no evidence of any confusion or distress except a severe headache. The next day, about twelve hours later, urine examination was negative and the leukocytes had risen to 13,400, with a normal differential count. Recovery was uneventful. The patient was discharged on the third day and readmitted on the fourth day. The complaint on readmission

was malaise, anorexia and violent headache. The general examination revealed no abnormality except that the blood pressure was 154 systolic, 100 diastolic. Eyeground examination was negative. The icterus index was 6. Treatment was symptomatic, the blood pressure gradually returning to normal within the week. The patient continues in good health two months later.

COMMENT

Because of the increase in blood pressure and the rather persistent headache, the possibility of cerebral irritation was considered. However, a lumbar puncture was not done, nor was it insisted on in view of the rapid amelioration of the symptoms and the negative eyeground examination. Through the agency of glycogen the liver is able to detoxify camphor by conjugation to nontoxic glucuronates.⁷ No evidence of liver damage has been apparent.

Council on Pharmacy and Chemistry

SPECIAL REPORT OF THE COUNCIL

THE COUNCIL RECENTLY DECADE INTERESTED IN THE RELATION OF AMIDOPYRINE TO GRANULOCYTOPENIA. A MEMBER OF THE COUNCIL WHO IS ESPECIALLY INTERESTED IN THE PROBLEM WAS ASKED TO PREPARE A REPORT ON THE SUBJECT. DR. PAUL REZNIKOFF OF CORNELL UNIVERSITY MEDICAL COLLEGE HAD PREPARED A BIBLIOGRAPHY ON THIS SUBJECT AND OFFERED THE MEMBER A REPORT BASED ON HIS INVESTIGATIONS. THIS WAS SUBMITTED TO THE COUNCIL FOR CONSIDERATION AND AS A RESULT THE COUNCIL SPONSORED PUBLICATION OF THE REPORT AS FOLLOWS TOGETHER WITH THE APPENDED COMMENT ON AMIDOPYRINE WHICH WAS PREPARED IN THE COUNCIL'S OFFICE.

PAUL NICHOLAS LEECH Secretary

THE RELATION OF AMIDOPYRINE AND THE BARBITURIC ACID DERIVATIVES TO GRANULOCYTOPENIA

The etiology of granulocytopenia has been a matter of speculation for a considerable time. It was generally considered that individuals suffering from this condition had constitutionally defective granulopoietic tissue and that one of many contributing factors might cause an acute depression of the bone marrow. Some of these contributing factors were fatigue, menstruation and infection.

The experimental production of agranulocytosis was reported by Kracke in 1932.¹ Madison and Squier² reported before the sixth annual meeting of the Central Society for Clinical Research in Chicago, Oct. 27, 1933, that an analysis of thirteen consecutive cases showed that all of the patients were physicians, nurses or patients under a physician's care and that they all had been using drugs containing a barbiturate combined with amidopyrine. Of even greater interest was the observation of these workers that three of their patients after recovery had an abrupt or fluctuating drop in granulocytes after medication. In two cases single doses of a benzene ring derivative caused such a relapse.

Following this report many physicians found a similar condition in their patients. Watkins³, Grant,⁴ Hench,⁵ and McGuire,⁶ all substantiate the observations of Madison and Squier. Since that time reports have been numerous indicating that amidopyrine is an important factor in the production of an acute attack of granulocytopenia. Rawls⁷ reported two

cases. Holten, Nielsen and Transbøl⁸ described five fatal cases in patients who developed granulocytopenia after they had been hospitalized for other disorders and who received amidopyrine. In a subsequent report Madison and Squier⁹ felt that in all their fourteen cases amidopyrine either alone or in combination with a barbiturate preceded directly the onset of the attack. Randall's¹⁰ case might be added to this series. Hoffman, Butt and Hickey¹¹ report that thirteen of fourteen patients had received amidopyrine alone or in combination with other drugs and died. The fourteenth patient took dinitrophenol four times a day for two weeks and is certain that she received no other drugs. She recovered. Zininger¹² found that two of her patients who died had been taking large amounts of amytal compound which contains amidopyrine, for a fairly long period of time. Recently Sturgis¹³ reported before the Association of American Physicians his observations on granulocytopenia. In agreement with other workers he finds that amidopyrine is an important factor in the production of granulocytopenia.

Attempts to reproduce this condition in rabbits with amidopyrine have thus far not been very successful. Madison and Squier⁹ produced a drop and an antemortem disappearance of granulocytes in one rabbit given large doses of allylisopropylbarbituric acid with amidopyrine (allonal) by mouth but failed in seventeen other rabbits to change the blood picture significantly. Hoffman, Butt and Hickey¹¹ obtained some depression in rabbits but they do not report any bone-marrow studies in their preliminary report.

Several questions have been raised by these important contributions to the question of etiology of granulocytopenia. Some of them are:

1 Is amidopyrine primarily responsible for the production of granulocytopenia?

2 Are the barbiturates themselves important in the causation of this condition?

3 Are any other predisposing, contributing or specific factors involved in this disease?

4 Assuming that amidopyrine is an etiologic agent in granulocytopenia, is it necessary to stop its general use, or modify its use, or do the conditions under which it is prescribed suggest that its relationship to granulocytopenia is within the realm of unavoidable accident and that any special caution may be disregarded?

As far as can be learned from the evidence at hand there can be no question that amidopyrine is very important in the production of granulocytopenia. In fact no other agent has been found, either chemical or bacterial, which has been a factor in causing so many attacks.

In the second place no definite case has been reported in which a barbiturate alone is responsible. From the present data it appears that barbiturates have little or nothing to do with granulocytopenia.

There also is no doubt that many cases of granulocytopenia have occurred in which amidopyrine has never been taken, or any other drug, for that matter. One patient had three attacks. She never took drugs of any sort previous to the attack and during her last attack she received a sedative containing amidopyrine, and she recovered promptly in spite of the constant administration of this drug throughout the acute phase of her illness. Moreover, it must be remembered that all patients who take or are given amidopyrine are suffering from some complaint or illness at the time the drug is being administered. There can be no question that fatigue¹⁴ and menstruation¹⁵

COUNCIL ON PHARMACY AND CHEMISTRY

Jour A M A
June 30 1934

are important factors in inducing an attack quite apart from the drug therapy.

When one considers the enormous amount of amidopyrine consumed and the relatively few individuals afflicted with granulocytopenia, it is obvious that one is dealing with a question of sensitivity in certain patients rather than with a universal action of the drug. In some respects it is analogous to the use of arsphenamines and the occasional occurrence of hepatitis or panmyelophthisis. It would be desirable to determine susceptibility in patients before amidopyrine is administered by the use of a test dose and a blood count, or perhaps by patch test but it is apparent that such a procedure is impractical. Of course, if a patient complains of a rash, dizziness or a chill after amidopyrine is given, it should be discontinued. Probably the safest course to follow is to use another drug such as acetylsalicylic acid, one of the barbiturates or codeine if any of these are just as effective as amidopyrine for any particular symptom. If, however, amidopyrine is found to be unrivaled in its action for a special complaint, it should not be administered for any great length of time, as a routine or in large doses unless white blood cell and differential counts are made at regular intervals. This is suggested, not because the occurrence of granulocytopenia is frequent but because when it does occur, it is an extremely serious accident. The indiscriminate and unnecessary administration of amidopyrine and the self administration by the public is certainly dangerous and should be discouraged.

Comment—The Council fully concurs in the recommendation of Dr. Reznikoff discouraging the indiscriminate administration of amidopyrine, particularly the exploitation to the public in which individuals are importuned to resort to self medication. There are on the market many products containing amidopyrine. Some of these products are advertised to physicians, others to the public. Because of interest in amidopyrine and products containing it, the following statement is opportune. Amidopyrine (Pyramidon) appeared on the clinical use of Nos 5 and 6, Lepine. On the Therapeutic Value of Pyramidon *Ztschr f klin Med* 1896 32, 1897, No 24. Pyramidon has been on the American market for at least twenty-five years under the pharmacopeial designation "amidopyrine" the drug has been marketed by American manufacturers for approximately twelve years.

Practically all pharmaceutical manufacturers and physicians supply houses sell one or more preparations which contain amidopyrine. In some instances the presence of the drug is indicated in the name of the preparation, in other cases the presence of amidopyrine can be determined only by a reading of the label or advertising material, in a few instances the presence of amidopyrine is not indicated in the name, on the label or in the advertising.

The introduction, more than ten years ago, of two widely advertised proprietary combinations of amidopyrine with a hypnotic drug of the barbituric acid series (Allonal and Peralga) was followed by the marketing of a number of preparations of this type. The following are representative examples (Amytal Compound (Eli Lilly & Co), Amido-Neonal (Abbott Laboratories), Cibalgine (Ciba Co, Inc), Pyraminal (H A Metz Laboratories), Phenamidol Compound Tablets (Abbott Laboratories), Phenamidol Compound Tablets (Sandoz Chemical Works), Amarbutal Tablets (A W Kretschmar) (Chicago).

Amidopyrine is also marketed in combination with drugs other than barbiturates. The following are examples of some of the many preparations that contain amidopyrine in combination with one or more other drugs: Amidophen-Lilly, Combral-Winthrop, Midol-General Drug Co, Dysco Tablets-Abbott, Cinchopyrine Tablets-Abbott, Kalms Johnson & Johnson, Mylin-Mifflin Chemical Corp, Benzod Compound Capsules-Abbott, Lumodrin-Winthrop and Hexin (Hexin, Inc).

The examples that have been cited serve also to show the desirability of the rule of the Council which provides against the recognition of proprietary, uninformative names for well known pharmacopeial substances or for mixtures of well known drugs.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS
PAUL NICHOLAS LEECH Secretary

ALPHA NAPCO AND DOSAGE FORMS OMITTED FROM N N R

Alpha-Napico, which is a compound solution of alpha naphthol, contains 10 Gm alpha-naphthol, 32 Gm glycerin 23.8 Gm soft soap (prepared from cottonseed oil and potassium hydroxide) water to make 100 Gm and gluside and essential oils to flavor. Although the description in New and Non official Remedies, 1933, did not mention beta-naphthol, it has been admitted that the product contains about 15 per cent beta naphthol. It is marketed by the Caryl Laboratories, Redondo, Calif.

- 1 Alpha Napico Camphor Nasal Unguent—containing 2 per cent alpha naphthol and 2 per cent camphor in petrolatum.
- 2 Alpha Napico Cones—made of Alpha Napico boric acid and sodium bicarbonate. They are recommended on the label for gynecological applications.
- 3 Alpha Napico Menthol Suppositories—containing Alpha Napico menthol oil of theobroma and yellow wax. On the label they are recommended for gynecological applications.
- 4 Alpha Napico Rectal Suppositories.
- 5 Alpha Napico Zinc Stearate Camphor Ointment.
- 6 Alpha Napico Zinc Stearate Powder.

Consideration of Alpha-Napico by the Council began in 1923. The product was rejected under the name Benetol in 1927. Following this there were three years filled with correspondence and discussion voluminous evidence of the Council's attempt to cooperate with a manufacturer who had difficulty in making his product and advertising methods acceptable to the Council. Finally, after many changes in composition, labels, dosage forms and advertising matter, the product was accepted under the name Alpha-Napico in 1930. The firm was given permission to use on labels and advertisements the statement "formerly Benetol" in accordance with the Council's custom when such changes of name are made one year from date of acceptance, through oversight, the firm was not informed at the time of acceptance of this limitation. Space does not permit recounting the long history of difficulties in making and keeping Alpha-Napico acceptable. The firm would promise compliance and seem to agree to required changes and limitations. But each submission of new circumvention of the rules or neglected them. When the period of acceptance expired in 1933, the firm was asked to submit the continued eligibility of the product for inclusion in New and Nonofficial Remedies. The Council's referee found that the material still contained objectionable statements, some of which were in direct contravention of the numerous explanations the firm had received.

In reporting on the eligibility of Alpha-Napico for reacceptance the Council's referee, without discussion of these infractions of the Council's instructions, considered the following more fundamental questions:

- (1) Is Alpha-Napico of sufficient prophylactic and therapeutic value as an antiseptic to warrant continued inclusion in New and Nonofficial Remedies and
- (2) Do not the complexities of the preparation and its dosage forms place the

in conflict with Rule 10 (Unscientific and Useless Articles—mixtures containing an excessive number of ingredients)?

The Alpha-Naphco preparations are recommended chiefly for local use as an antiseptic and germicide. The present evidence of their usefulness for this purpose is inadequate, nor is there convincing proof that the alpha naphthol by itself exerts any more antiseptic action than do some of the other constituents in these preparations. The phenol coefficient of Alpha-Naphco is said to be 146. Evidence was supplied in March 1932 by reports from a commercial laboratory that a 1:300 solution of Alpha-Naphco will kill *Staphylococcus aureus* in five minutes. The preparation is a weak antiseptic and germicide.

These reports of the commercial laboratory which were considered by the Council in February 1931 compared the antiseptic and germicidal properties of Alpha-Naphco with those of phenol, cresol and surgical solution of chlorinated soda when tested against *Staphylococcus aureus* in water, blood serum, saliva, and equal parts of saliva and blood serum. The preparation was found to be much more active than surgical solution of chlorinated soda in the presence of saliva and of serum, about three times as active as phenol and slightly more active than compound solution of cresol, U S P. Other tests with Alpha Naphco were also made against *B. pyocyaneus*, *B. typhosus*, and *B. anthracis*. The protocols of the latter tests as given in the reports are too brief to be of value there being no complete statement of the conditions. It must be pointed out that the other substances with which Alpha-Naphco was compared in these tests are generally considered to be weak antiseptics and the value in such test tube experiments in proving the efficacy of antiseptics when applied to the skin or mucous membranes is questionable. The firm was informed (March 19, 1932) that tests under such conditions do not simulate those in wounds or infected body cavities.

The value of Alpha-Naphco as an intestinal antiseptic was taken up in another report, at which time the results of tests on human beings were presented by the firm and discussed. These tests showed that the compound acted as an intestinal antiseptic only in very large doses and the claims for its use for this purpose were not accepted. Except for these tests, no evidence has been presented by the firm to support its claims for the antiseptic or germicidal action of alpha-naphthol when applied to skin or mucous membranes.

It is pointed out in Cushing's 'Pharmacology and Therapeutics' that substances such as pyrogallol, naphthol and chrysarobin may owe their effects in skin diseases as much to slight irritation and improved nutrition as to their retarding effect on the growth of micro organisms. It certainly seems that there are many antiseptics other than those of the phenol-cresol naphthol group which are stronger and preferable for use on the skin, especially in first aid.

The use of naphthol preparations in the nose and throat is of very doubtful value. Both alpha and beta naphthol have an irritating effect on the mucous membranes. The antiseptic action of Alpha-Naphco when used as a spray or gargle or its value in preventing colds, as claimed by the manufacturer is questionable. The Council has opposed the exploitation of antiseptic mouth washes and gargles.

Similar questions may be raised in regard to the three suppository preparations offered by the firm. Whatever favorable effects these may have might be attributed to the action of the wax or boric acid vehicles. The Alpha-Naphco Zinc powder is probably little more useful than other similar powders not containing alpha-naphthol.

Attention must also be called to the constituents other than alpha naphthol of several of the preparations. Two of them contain camphor, which is itself an antiseptic. One of the suppositories contains menthol, and the cones contain a large amount of boric acid in addition to the Alpha-Naphco. It also is not unlikely that the soap contained in these preparations may exert an antiseptic effect in contact with the skin and mucous membranes almost equal to that of the other constituents.

Since the first presentation of the products, a few minor changes have been made in the composition of the preparations. The original Benetol ointment contained menthol 0.3 per cent, zinc oxide 5 per cent and boric acid 3 per cent in addition to the other constituents now in the ointment and these have

been omitted from the present Alpha-Naphco Camphor Ointment. Other changes in composition were omission of 0.1 per cent and 0.2 per cent menthol, respectively, from the cones and rectal suppositories. The original Benetol powder contained 3 per cent bismuth subnitrate, 12 per cent zinc oxide and 30 per cent boric acid, which were later omitted. No changes were made in Alpha-Naphco (Benetol) itself or in the nasal unguent or the menthol suppositories. In retrospect it appears that the only noteworthy changes were those made in the ointment and in the powder. Although these revised formulas were considered at the time not to be in conflict with rule 10, the Council decided, on reconsideration, that many of the preparations are still too complex and therefore are in conflict with rule 10. Were Alpha-Naphco able to stand on its own merits, it would hardly seem necessary to include camphor in the preparations.

The Council voted that Alpha-Naphco and its dosage forms be omitted from New and Nonofficial Remedies (a) because there is no reliable evidence that this weak antiseptic is of prophylactic or therapeutic value, (b) because the complexities of the mixtures place them in conflict with rule 10, and (c) because of difficulties in controlling the claims and advertising matter of the firm.

ASTHMOLYSIN AND SPASMOLYSIN NOT ACCEPTABLE FOR N N R

Asthmolysin, manufactured by Dr. Kade of Berlin, is promoted by H. H. Beisner of New York City. It is claimed to be a preparation of outstanding therapeutic value in asthma. It has been the subject of many inquiries addressed to the Council in the past ten years. Asthmolysin is stated to have been 'discovered during 1912 by Dr. Weiss, an authority on Asthma, of Berlin, Germany.'

It is alleged to be "prepared according to a special method," details of which are not given. Other advertising states that the product consists of the active principles of the suprarenal and hypophysis cerebri prepared according to a secret process. No biologic or pharmacologic standardization is mentioned on the label or in the advertising. The mixture of pituitary extracts with epinephrine if, indeed, there is epinephrine in the preparation, would appear to be therapeutically inconsistent, since hypophyseal extracts, by their general stimulation of smooth muscle, are contraindicated in asthma because of the possibility of enhancing or aggravating the constriction of the bronchioles and alveolar ducts. Any effect in asthma which this preparation may exert is therefore in spite of the pituitary extract which is said to be present, a mixture containing epinephrine and pituitary is unscientific and not to be commended.

It was pointed out in THE JOURNAL, Oct. 1, 1927, page 1170 that the firm alleged that it had obtained testimonials from 121 physicians. As THE JOURNAL stated,

Such testimonials given for a semisecret preparation of unscientific character are no credit to those members of the supposedly learned profession that gave them.

Testimonials, whether lay or professional, are a time-honored and overworked means of promoting valueless products concerning which no truly scientific evidence of therapeutic efficacy can be adduced.

A postscript to a letter issued by the firm states

You may have cases of EPILEPSY. If so attached reprint on Spasmolysin will interest you.

According to a "reprint," Spasmolysin has the following formula (?) Asthmolysin + Parathyroid Extract. According to the generally accepted criteria for formula writing, the foregoing presents certain obvious if not glaring deficiencies. No one has ever demonstrated any relationship between suprarenal, hypophysis and parathyroid, on the one hand, and epilepsy on the other. Spasmolysin would then seem to be a preparation typical of the unscientific, irrational mixtures which will be avoided by the scientifically trained physician.

The Council declared Asthmolysin and Spasmolysin not acceptable for New and Nonofficial Remedies because they are semisecret, unscientific preparations marketed under proprietary and therapeutically suggestive names with exaggerated and unwarranted claims, which tend to replace well known drugs of proved effect in corresponding disorders.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG Secretary

IRRADIATED VITAMIN D PASTEURIZED MILK

- (1) ADOHR MILK FARMS'
- (2) JOFFE'S
- (3) F. B. MALLORY, INC.
- (4) PURE WHITE DAIRY COMPANY'S JERSEY, SPECIAL AND HOLSTEIN
- (5) ROCHESTER DAIRY COMPANY'S
- (6) TELLING-BELLE VERNON COMPANY'S
- (7) VALLEY BELL

Distributors—(1) Adohr Milk Farms, Los Angeles, (2) Joppe's Dairy, Grand Rapids, Mich., (3) F. B. Mallory, Inc., Springfield, Mass., (4) Pure White Dairy Company, Tulsa, Okla., (5) Rochester Dairy Company, Rochester, Minn., (6) The Telling-Belle Vernon Company, Cleveland, (7) Valley Bell Dairy Company, Inc., Charleston, W. Va.

Description—Bottled pasteurized vitamin D milk irradiated with ultraviolet rays (patent No. 1,680,818).

Preparation—The milk complies with legal requirements and is pasteurized by the standard holding method. For description of irradiation, see THE JOURNAL Oct 7, 1933, page 1155.

Vitamins—Clinical investigation shows this milk to be a reliable antirachitic agent if proper amount is used. Contains 135 U. S. P. X (Revised, 1934) vitamin D units per quart.

Claims of Distributors—Irradiated antirachitic pasteurized milk having otherwise the flavor and food values of usual pasteurized milk.

STOKELY'S FOR BABY SPECIALLY PREPARED STRAINED PEAS SEASONED WITH SALT

Manufacturer—Stokely Brothers & Company, Inc., Indianapolis.

Description—Sieved peas slightly seasoned with salt. Largely retains the natural minerals and vitamins.

Manufacture—Fresh peas, harvested at the height of development while still in the tender, succulent stage, are shelled, thoroughly washed, inspected to eliminate any defective peas, and graded; the selected peas are given a minimum blanch in hot water, removed from the water, steamed in a closed kettle until soft, comminuted, canned and processed as described for Stokely's Strained Green Beans (THE JOURNAL, May 26, 1934, p. 1762).

Analysis (submitted by manufacturer) —		per cent

Calories—0.5 per gram 14 per ounce

Vitamins—The natural vitamin content is retained in large measure in the manufacturing process by the use of equipment and procedure which exclude incorporation of air; the vegetable material is exposed to steam only.

Claims of Manufacturer—Supplementary to the infant milk diet, and valuable for children and adults on soft diets. Has

smooth consistency and supplies desirable bulk without roughness. The straining renders the nutrient content readily available for digestion. Scientifically prepared to retain in high degree the natural flavor, mineral and vitamin values. Seasoned to bring out full flavor and packed in enamel lined cans. Requires only warming for serving.

18-K BRAND VACUUM PACKED FRESH ROASTED COFFEE

Manufacturer—Winston and Newell Company, Minneapolis.

Description—Ground roasted coffee packed in tins under "vacuum."

Manufacture—The coffee beans are blended and roasted in one operation, screened and granulated. The chaff is removed by air, ground and removed with the coffee. The coarsely ground coffee is packed in tins which are sealed under "vacuum."

(1) SANTA FE BRAND CRYSTAL WHITE TABLE SYRUP

(2) SANTA FE BRAND GOLDEN SYRUP

Distributor—The Ranney-Davis Mercantile Company, Arkansas City and Anthony, Kan., Enid, Ponca City and Woodward, Okla.

Packer—The Hubinger Company, Keokuk, Iowa.

Description—(1) Table syrup, corn syrup flavored with sucrose syrup and vanilla extract.

(2) Table syrup, corn syrup flavored with refiners' syrup.

Manufacture—The same as Hubinger Crystal White Syrup, THE JOURNAL, Jan 27, 1934, page 293, and Hubinger Golden Table Syrup THE JOURNAL, Jan 20, 1934 page 213.

Claims of Manufacturer—Recommended for use as an easily digestible and readily assimilable carbohydrate supplement to milk in infant feeding and as a syrup for cooking, baking and the table.

BEECH NUT PRESSURE COOKED FARINA- OATMEAL-WHEAT GERM BLEND CERE-JEL

(SLIGHTLY SEASONED WITH SALT)

Manufacturer—Beech-Nut Packing Company, Canajoharie, N. Y.

Description—Sieved cooked farina, oatmeal and wheat germ retaining in high degree the natural vitamin and mineral content, seasoned with salt.

Manufacture—Farina, oatmeal, wheat germ and salt in definite proportions are cooked in water, strained, packed and processed as described for Beech-Nut Pressure Cooked Farina Cere-Jel (THE JOURNAL, May 26, 1934 p. 1762) and Beech-Nut Strained Carrots (THE JOURNAL, Nov 11, 1933, p. 1562).

Claims of Manufacturer—Especially intended for infants, children and convalescents and for special smooth diets. Only warming is required for serving. The natural mineral and vitamin values are efficiently retained.

MEAD'S BREWERS YEAST POWDER
MEAD'S BREWERS YEAST TABLETS*Manufacturer*—Mead Johnson and Company, Evansville, Ind*Description*—Dried brewers' yeast in powder form or in tablets*Manufacture*—Brewers' yeast is cultured, harvested, spray dried and packed in powder form or in 6 gram tablets (compressed) For spray drying, a suspension of the yeast in water is sprayed into a current of heated air Dehydration is practically instantaneous, the dry powder falling to the base of the drying chamber, from which it is automatically and continuously removed The temperature attained by the yeast is less than 100 C and probably not over 70 C and the heating time probably less than thirty secondsThe yeast is cultivated by inoculating a sterilized wort containing dextrose, sucrose and raffinose of molasses and other vegetable products and nutrient minerals of organic and inorganic origin, with a pure culture of *Saccharomyces carlsbergensis* The fermentation is carried on in a filtered air atmosphere and is much slower than for aerated bakers yeast The yeast is harvested centrifugally

SATURDAY, JUNE 30, 1934

THE RIDDLE OF MIGRAINE

The truth of the idea that "a multiplicity of remedies advocated for the treatment of any one disease indicates poverty rather than wealth in therapy" is well illustrated by migraine. A hundred miscellaneous "remedies" have been advanced for the treatment of migraine, and still it is largely incurable. The addition of more remedies for migraine merely adds to the embarrassment of riches unless the new remedies throw a ray of light on the essential nature of the condition and make treatment more rational.

Thomas C. Hunt,¹ in an article on bilious migraine, reports a reinvestigation by newer methods—bile drainage and cholecystography—of the old and generally abandoned idea that migraine has something to do with biliary disturbance. He concludes that local gallbladder disease or dysfunction is *not* a cause of migraine but probably rather a result. This does not, however, discourage him from trying bile salts for the purpose of influencing "liver function," which he still believes must somehow be deranged in this disease. He reports that sodium glycocholate and a proprietary preparation of dehydrocholic acid produced considerable improvement in nineteen among twenty-two patients, provided the use of the remedy was maintained and its dose doubled when an attack seemed to be threatening. Of the patients that were relieved, nine had no attacks while under treatment and the others had the number of attacks considerably reduced. He believes that this result suggests that some hepatic dysfunction may be the cause of migraine in certain cases. Unfortunately this conclusion *et juvantibus* as to the cause of migraine is hardly tenable, as strangely similar results are claimed for quite a number of other treatments from the correction of eye strain to avoidance of "offending" foods as determined by skin tests, or the use of peptone, of cannabis or of glyceryl trinitrate.

Obviously, when so many different agents can influence a certain condition the rational view must be unitarian and focus attention on the one factor com-

mon to them all. This must be the psychic factor. Therefore, instead of proving the thesis of a "biliary" migraine, the partial success of the bile salt treatment merely adds another means of escape from the manifestations of this condition, provided the physician as well as the patient has sufficient faith in it. When a rational remedy is found, its effects are much more definitely predictable than is evidently the case with bile salts in the treatment of migraine.

In the same way, success in securing relief of an attack of migraine by means of slow hypodermic injections of epinephrine, in doses of from 0.6 to 1.3 cc of the solution, cannot be cited as a proof of the "allergic" nature of this disease or as analogous to the definite effect of epinephrine in asthma. It is even impossible to speculate on the manner in which such relief is obtained in those cases in which it is secured. Nearly every well developed attack of migraine passes through two stages: that of vasoconstriction followed by vasodilatation, and a vasodilator such as glyceryl trinitrate, which may produce relief in the one stage, may aggravate the other. In experiments, the brain volume has been shown to be increased—probably passively—by epinephrine, and, as Hunt finds that the effect is better the earlier in the attack it is given, which would coincide with the stage of vasoconstriction, the actual mode by which epinephrine produced relief might be the same as that of glyceryl trinitrate. Perhaps epinephrine is a remedy of real value as far as correcting the abnormal distribution of the blood in an attack of migraine is concerned, but there is need to know whether it is to be used in the stage of vasoconstriction or the stage of vasodilatation.

THE MECHANISM OF EXOPHTHALMOS

"Apart from gross neoplastic and inflammatory lesions of the orbit, the mechanism of exophthalmos is still little understood." This curious statement emanates from the textbook of Brain,¹ one of the leading members of the distinguished London school of neurologists, nevertheless the mechanism of exophthalmos is well understood, though the knowledge would seem to be poorly disseminated. This fault must be laid in part at the door of the anatomists, who, though describing accurately enough the external ocular muscles controlled by the third, fourth and sixth cranial nerves, have failed to teach the known anatomic knowledge in regard to the antagonists of these muscles, which are unstriated and controlled by sympathetic nerves. The physiologists, too, must share the blame, for what explanation do they offer of the delicately balanced muscular mechanism that results in normal binocular vision and in diplopia when this mechanism is disturbed? Are we to believe that the powerful rectus muscles do not contract against equally

¹ Hunt T. C. Bilious Migraine. Its Treatment with Bile Salt Preparations. *Lancet* 2: 279 (Aug. 5) 1933.

¹ Brain W. R. *Diseases of the Nervous System*, London, Oxford University Press 1933.

powerful antagonists? Such an assumption is physiologically untenable

Fortunately the *argumentum ad absurdum* is not required, for sound anatomic and physiologic evidence is available. In 1858 Heinrich Muller described briefly three groups of plain muscle fibers—one bridging over the infra-orbital fissure, and one in each eyelid—which constitute the so-called muscle of Muller. It has been theoretically advanced that a spastic condition of Muller's muscle causes the type of exophthalmos now under discussion, but its obvious inadequacy from both its size and its position to produce exophthalmos makes such an explanation unsatisfactory. Other theories have been advanced but none have been accepted.

Landstrom² in 1907 published the results of a careful histologic study of the orbital contents. He removed intact by subperiosteal dissection the contents of several orbits, together with the lids and septum orbitale, and sectioned them serially in various planes. His preparations revealed a well developed cylinder of plain muscle arising from the septum orbitale anteriorly and inserted just posterior to the equator of the ball. The results of his work he summarizes thus: "The bulbus oculi, enclosed within a connective tissue capsule and surrounded by a pad of fat, is suspended in the orbit anteriorly by a cylinder-shaped plain muscle running from the septum orbitale to the equator of the bulbus, and posteriorly by the rectus muscles." Exophthalmos is produced when the hypertonicity of this cuff of plain muscle—the opponens recti—overcomes the tonus of its antagonists—the rectus muscles.

Landstrom's histologic work served to confirm the important observations of MacCallum and Cornell.³ These authors removed the roof of the orbit and orbital fat in dogs and on electrically stimulating the cervical sympathetic produced great exophthalmos and observed peristaltic waves passing backward throughout the tissue surrounding the eyeball. By dissection and histologic study they were able to demonstrate the presence of smooth muscle fibers forming a conical mantle about the ball, with anterior and posterior attachments essentially as described later by Landstrom.

The literature has been reviewed by Friedgood⁴ in a paper confirming and greatly extending some observations of Barker and Hanes.⁵ His paper contains abundant evidence from the clinical side that exophthalmos and other eye signs are the result of hypertonicity of the plain muscles of the orbit due to sympathetic overstimulation. It is, of course, well known that enophthalmos, myosis and ptosis (Horner's syndrome) are due to interruption of the sympathetic innervation of orbital plain muscles.

POSTOPERATIVE EDEMA

Edema is one of the common symptoms with which the practicing physician is forced to cope. Certain types of edema have long been recognized as concomitants of circulatory or renal disorders, notably in association with heart disease, venous and lymphatic obstruction and acute glomerular nephritis. Of late, considerable interest has been centered in a formerly unrecognized cause of fluid accumulation in the tissues in which the dominant factor is a lowered content of protein in the blood plasma. Experiments on animals have confirmed the development of so-called nutritional edema, commonly described as "war edema" during the World War, as a result of protein deficiency in the diet. As a recent writer¹ has summarized present knowledge, chronic malnutrition, from whatever cause, and particularly dietary deficiency of protein, is invariably associated with a decrease in plasma protein. The albumin fraction is especially affected, because it is formed with greater difficulty than globulin. If the reduction in plasma protein, and especially of albumin, is sufficient edema develops. In so-called nephrosis of man, in which two of the chief manifestations are the excretion of large quantities of protein in the urine and edema, accumulation of fluid in the tissues usually begins when the level of serum protein falls below 5 Gm per hundred cubic centimeters. This so-called edema level is subject, however, to variation, depending on the relative proportions of albumin and globulin.

Generalized edema of the tissues sometimes appears as an annoying complication following ordinary surgical procedures. The explanation has never appeared to be quite as simple as it seems to have become in the classic types of nephrosis. Surgical investigators have pointed out that the lowering of the serum protein and of the serum albumin is of importance in tending to make fluid accumulate in the tissues, but edema can readily occur in the presence of normal values. The latest researches of Jones, Eaton and White² at the Massachusetts General Hospital in Boston represent an effort to examine some of the heretofore little understood possibilities experimentally, notably to develop postoperative edema. For this purpose they have attempted to reproduce in animals the actual condition occurring in ordinary surgical procedures on human beings, particularly as related to abdominal surgery. In these experiments they have tried to control and study general nutrition from the point of view of caloric requirements, the intake of nitrogen, sodium chloride and water, respectively, the absorption of nutritive material from the gastro-intestinal tract, serous drainage, abscess formation, and, to a certain extent, surgical shock following general anesthesia and an abdominal operation. Factors that seemed to be

secondary to those listed and that were beyond control were those related to hepatic and renal insufficiency. The factors that were approximately under control were those frequently encountered in operative conditions, particularly in those involving operations on the gastro-intestinal tract.

The factor of undernutrition, and particularly of protein starvation, was found to be of fundamental importance, as was anticipated. In numerous instances, peripheral edema and visceral edema of marked degree occurred in the presence of normal values for serum protein and albumin. Again, the serum protein depletion was not always sufficient to precipitate the edematous condition. An adequate fluid intake also was always essential. As the Boston investigators remark, when the lack of nitrogen was acute, water tended to accumulate in the tissues more rapidly, provided the fluid intake was considerable.

The importance of serous drainage as a factor in producing edema after operations is strongly suggested by these studies. Jones and his collaborators admit the improbability that the actual loss of protein occasioned by drainage of any of the fluids would in itself seriously alter the serum protein content under normal conditions. In association with marked undernutrition and the administration of moderately large amounts of fluid and salt, it is entirely possible that such a loss of protein may be of real importance in the production of edema, probably through a lowering of the serum protein. Sepsis appears to be of great moment. It is possible, according to the Boston investigators, that there is a constant general reaction of the body to histamine or histamine-like substances in the presence of abscess formations, with resulting increased capillary permeability. Under such conditions, lack of nitrogen and a somewhat excessive fluid intake might result in a striking accumulation of fluid in the tissues.

One striking feature of the experiments was the edema noted in various important viscera. Sometimes there was an involvement of the heart, intestine, pancreas and kidneys, leading one to wonder whether such changes may not so alter the functions of these organs as to interfere seriously with homeostasis. Under such conditions the circulatory, urinary, hepatic and digestive systems, for example, may all be somewhat disturbed and, from a lack of correct individual functioning, may fail to coordinate properly among themselves. The diarrhea that occurred in several of the animals, for example, appeared always to be a concomitant of edema of the intestinal tract. With diarrhea, all the nutritional processes were manifestly upset and a vicious circle was at once established. From the standpoint of the clinical application of these observations, the Boston investigators believe, one can readily conceive of the difficulties that may face the depleted preoperative patient when subjected to any major surgical procedure that necessarily involves further deple-

tion, surgical shock, hypodermoclyses and possible surgical drainage. Obviously, they conclude, measures tending to maintain nutrition must be instituted, and the dangers of flooding the patient with excessive amounts of water and salt must be minimized as much as possible.

Current Comment

THE INDEX NUMBER

This issue of THE JOURNAL contains the index covering the numbers from January through June. Because of the length of the index and the vast amount of material included in this period, it is necessary to omit from this issue some of the departments that are usually included. It is, moreover, impossible, because of the limitations on our space, to make adequate comment on some of the important actions taken by the House of Delegates of the American Medical Association at the annual session. It is proposed, however, to call specific attention in forthcoming issues to many of these important actions and to emphasize particularly economic problems which the House of Delegates feels should be brought prominently to the attention of the profession.

AMIDOPYRINE AND GRANULOCYTOPENIA

Elsewhere in this issue appears a statement prepared for the Council on Pharmacy and Chemistry by Dr. Paul Reznikoff on the relation of amidopyrine and the barbituric acid derivatives to granulocytopenia. In sponsoring this statement the Council also appended an informative comment. Apparently amidopyrine may cause granulocytopenia to occur in certain patients but there is no definite evidence that barbituric compounds alone are responsible. On the contrary, it appears from the evidence available that barbiturals have little or nothing to do with the occurrence of this condition. Considering the amounts of amidopyrine that have been used, relatively few cases of agranulocytosis have developed. Presumably, therefore, the occurrence of this condition in a patient using amidopyrine indicates an unusual degree of sensitivity to the drug. Amidopyrine is marketed not only in combination with other drugs such as the barbituric derivatives but also with antipyretics such as acetphenetidin and acetylsalicylic acid, and with other drugs. Unfortunately, many of the drug firms do not name the products in such a manner as would indicate readily the presence of amidopyrine. Furthermore, there are a number of nostrums sold directly to the public which contain amidopyrine. The Council points out that this incidence of agranulocytosis as a result of the administration of amidopyrine serves to show the advisability of the rule of the Council on Pharmacy and Chemistry which provides against the recognition of proprietary uninformative names for well known pharmacopoeial substances or for mixtures of well known drugs. It seems probable that drugs other than amidopyrine will be found also to cause granulocytopenia.

PROCEEDINGS OF THE CLEVELAND SESSION

MINUTES OF THE EIGHTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT CLEVELAND, JUNE 11 15, 1934

(Continued from page 2119)

Second Meeting—Tuesday Morning, June 12

The House of Delegates was called to order at 9 30 a m by the Speaker, Dr F C Warnshuis

It was moved by Dr J D Brook, Michigan, seconded by Dr Mather Pfeiffenberger, Illinois, and carried, that the signed attendance slips constitute the roll call of the House

On motion of Dr Charles H Goodrich, New York seconded by Dr Grant C Madill, New York, and carried, the House dispensed with the reading of the minutes

Report of the Reference Committee on Credentials

Dr J D Brook, Chairman, reported that sixty-two additional delegates had filed proper credentials with the committee making a total registration of 164

There being no objections, the Speaker stated that the report of the committee would be received

Report of the Reference Committee on Reports of Officers

Dr J Gurney Taylor, Chairman, presented the following report

1 *Speakers Address* Your committee approves the recommendation relative to suitable comments being added to committee reports, especially when they may relate to major policies

Your committee feels that it is not desirable to abolish the Reference Committee on Rules and Order of Business, since occasions may yet arise when the necessity of such a committee will be apparent

Your committee further recommends that amendments be not adopted to create a Reference Committee on Medical Economics We believe the problems relative to Medical Economics should be referred to the Reference Committee on Legislation and Public Relations Believing that this subject comes under the jurisdiction of this committee, we find no authority in the Constitution and By-Laws relative to the creation of a committee on economics

Your committee does not recommend the appointment of a nominating committee, feeling that the present system has been adequate and has been acceptable to the Fellowship

2 *Presidents Address* Your committee endorses the many sane and practical general suggestions offered in the message of the President, especially those relative to the postgraduate extension work We suggest that the Council on Medical Education and Hospitals consider the feasibility of assisting and encouraging the state medical societies in the establishment of postgraduate courses of instruction

Relative to the method of procedure regarding expert medical testimony it is suggested that each state medical society establish cooperation with its state bar association in an effort to correct this abuse

3 *President Elects Address* Your committee wishes to commend particularly that paragraph of the address of the President-Elect in which he said It is sad to relate that mighty forces have been at work to sow the seeds of discontent in the ranks of organized medicine and to destroy the faith in that leadership which is based on the sacred traditions of sacrifice and devotion to the idealism of medical service In times like these loyalty to the organization and sacrifice of individual prestige to the good of all are necessary for medical advancement

4 *Report of the Judicial Council* Your committee believes that this report contains much material for serious thought

and would emphasize the importance and appreciation of local responsibility by the membership, believing that the prosecution should originate in the local county societies

Respectfully submitted

J GURNEY TAYLOR, Chairman
W G RICKER
WELLS TEACHNOR SR
J R BLOSS
W D JOHNSON

On motion of Dr Taylor, seconded by Dr Joseph F Smith, Wisconsin, and carried, the report of the Reference Committee on Reports of Officers was adopted

Report of the Reference Committee on Legislation and Public Relations

Dr Charles E Mongan, Chairman, presented the following report

1 Your committee heartily approves of the excellent work done by the Bureau of Legal Medicine and Legislation in the matter of NIRA legislation and urges the Bureau to continue to watch the development of codes likely to affect the practice of medicine and especially to endeavor to protect the physician engaged in the practice of roentgenology

2 *Federal Emergency Relief Administration* Your committee commends the interventions of the Bureau in the development of emergency medical relief service and approves of its acts, your committee recommends that the proper agency of the American Medical Association make an early survey of conditions existing at this time with a view to correcting discrepancies in the service and making possible improvements

3 Your committee would point to the fact that the freedom of choice of physician has been preserved in this service and that for the first time the fact that only the medical profession may properly evaluate medical service has been recognized

4 *Federal Civil Works Administration* This report is historical The only phase of this service of interest now is the delay in adjustment of claims of physicians for services rendered This delay is due largely to the need of correction of errors in the reports of physicians who rendered the service The Bureau should continue in touch with the situation and facilitate the proceedings as much as possible

5 *Hospitalization of Veterans* This report reiterates and presents in compact form the oft repeated position of the American Medical Association on this subject and recommends that it be approved as such

6 *Contract Surgeons of the Spanish-American War* In the light of the report the contract surgeons of the Spanish-American War deserve special consideration There is no reason why they should not be given the same treatment as others who rendered the same or similar service, particularly the contract nurses

7 *Library of the Surgeon-General's Office* Your committee approves the observations made in the report and joins in the recommendation that the profession unite in an effort to preserve and protect this institution

8 *Food, Drug and Cosmetic Legislation* The bureaus of the American Medical Association are evidently in close touch with this matter The position of the Association on the subject is well known and should be reiterated and emphasized It is well to add to the activities of the Association in this connection the subject of cosmetics and truth in advertising

9 Report of Committee on Legislative Activities Your committee commends the Committee on Legislative Activities for its judgment and acts, particularly with reference to the question of veterans' legislation Your committee would impress on the several state societies the necessity of educating the public on the science of medicine and the public welfare Each member of the House of Delegates should feel it his bounded duty to impress on his state society and county societies the importance of individual efforts in this direction

10 Resolutions on State and Federal Relief Committees Your committee recommends the adoption of the resolutions, with the observation that not only state relief commissions but county administrations as well should have physicians in their personnel

11 Resolution on Free Choice of Physician Your committee finds that the matter referred to is covered by a federal statute (enacted in 1916) and not by rules and regulations Your committee recommends that this resolution be referred to the Board of Trustees for further consideration and suitable action

12 Resolutions on Discrimination Against Certain Members of the Medical Profession The matter was fully covered by the resolution adopted by this House in 1933 as follows

Resolved That the American Medical Association in annual session assembled condemns the persecution of any individual on account of race or religion by any state or under any flag

13 Resolutions introduced by Dr Holman Taylor, Texas, with reference to support of the Army Medical Library The Reference Committee approves the resolutions and recommends their adoption

Respectfully submitted
CHARLES E. MONGAN, Chairman
GRANT C. MADILL
C. W. WAGGONER
HOLMAN TAYLOR
JOSEPH F. SMITH

On motions, duly seconded and carried, each section of the report of the Reference Committee on Legislation and Public Relations was adopted, after which the report was adopted as a whole on motion of Dr Mongan, seconded by Dr Mather Pfeifferberger, Illinois, and carried

Report of the Reference Committee on Sections and Section Work

Dr Isaac A. Abt, Section on Pediatrics, presented the following report

Your committee wishes to commend the sentiment expressed concerning the activities and worth of Dr John E. Lane. The House of Delegates recognizes his long and distinguished service in the House and as a member of the Council on Scientific Assembly

Your committee wishes to approve the program initiated this year of holding General Scientific Meetings on Monday and Tuesday of each annual session

Your committee also approves the setting aside of one session of the Section on Miscellaneous Topics to consideration of a program on Forensic Medicine, as well as a session of the same section for discussion of the subject of Nutrition

Your committee recommends the adoption of the resolution of Dr Albert Soiland and suggests that the House of Delegates authorize the Section on Radiology cordially to invite the fifth international congress to be held in America, at such time and place as may be decided on by the International Committee of the Fifth Congress of Radiology

Finally, your committee desires to commend the Council on Scientific Assembly for its splendid work during the past year which expresses itself in the excellent scientific program to be presented at this meeting of the Association

Respectfully submitted
ISAAC A. ABT, Chairman
A. R. McCOMAS
C. W. ROBERTS
W. H. SEEMANN

On motion of Dr Abt, seconded by Dr J. Gurney Taylor, Wisconsin, and carried the report was adopted

Report of Reference Committee on Medical Education

Dr Irvin Abell, Chairman, presented the following report

1 The Reference Committee on Medical Education has considered the report of the Council on Medical Education and Hospitals, as published in the Handbook, and heartily commends it in its entirety

Paragraphs 1 and 16, dealing with Americans studying in countries other than North America, are particularly worthy of attention in view of the great number desiring to enter the field of medicine. Paragraph 5 shows an astonishing ratio of college students to the whole population, it being in the United States 1 to 125, and varying in foreign countries from 1 to 455 to 1 to 1,150. Obviously, this is an economic situation about which this organization can do nothing further than to make the facts known

Paragraphs 4 and 17 indicate the great activity of the Council in that 755 hospitals were visited by its staff during the year and that there were 200 smaller hospitals to which the staff of the Council has been able to bring considerable assistance by giving suggestions regarding organization and operation

The conclusion of the Council, expressed in paragraph 8, that it would be undesirable to abolish examinations by state boards and substitute therefor a diploma is commended. Your committee would urge all candidates for licensure to take the examinations of the National Board, since its certificate is recognized by the majority of the state licensing boards

Publications referred to in paragraphs 11, 12 and 13 comprise an enormous amount of important data of incomparable value to the profession and furnish the record of a most worthwhile work of the Council

Paragraph 14 refers to a comprehensive survey of medical education now being undertaken. The report of this activity will be awaited with great interest because of the number of years that have passed and of the great changes that have occurred in educational procedures since the last survey

It is interesting to note in paragraph 19 that the general hospitals show an average of 155,000 unoccupied beds and that the special hospitals had an average of 61,754 unoccupied beds in 1933. This is forceful testimony of the effects of the depression as well as of excessive hospital facilities

2 Supplement A of the Council, which formulates essentials for an approved special examining board, is recommended for adoption with the suggestion that definition of special fields be made more elastic so that, for instance, one contemplating specialization in obstetrics would not be required to take the examination in gynecology also, and vice versa. Further, that one desiring to specialize in gynecology and abdominal surgery could apply for examination in such fields without, as under the proposed set up, also being required to take the examination in general surgery and obstetrics. The field of internal medicine could be subdivided so as to cover those who restrict their activities to one of its integral parts

3 The resolution introduced by Dr G. H. Mundt, delegate from the Illinois State Medical Association, specifying that the staffs of hospitals designated for intern training should comprise only members in good standing in their local county medical societies, is referred to the Council on Medical Education and Hospitals with the following comment

Your committee approves the principle of this resolution but feels that its general application at the present time is inadvisable. Paragraph 3 of the report of the Council indicates that approximately 87 per cent of the staffs of the 6,437 hospitals of the country are members of the American Medical Association

4 The resolutions introduced by Dr George M. Fisher, delegate from the Medical Society of the State of New York, referring to the restriction of x-ray practice, both diagnostic and therapeutic to the direct supervision and control of duly licensed physicians or dentists, are approved

5 The resolutions introduced by Dr E. P. North, delegate from the Missouri State Medical Association requesting that the American Medical Association shall not approve any institution for any purpose unless and until such institution shall be

officially in the approved list of component medical society or societies in the jurisdiction of which such hospital or institution is located or operates are disapproved

6 The resolution introduced by Dr C B Reed delegate from the Illinois State Medical Society, requesting establishment of standards, ratings and inspections of training schools in physical therapy, is covered in the report of the Board of Trustees, page 49, as follows

"The Council on Medical Education and Hospitals is cooperating with the Council on Physical Therapy in formulating essentials for Physical Therapy and Occupational Therapy Schools"

7 The resolutions introduced by Dr Holman Taylor delegate from the State Medical Association of Texas providing that the American Medical Association respectfully request of proper authorities the setting aside of an adequate sum for the construction of a new building to house the Army Medical Library and the Army Medical Museum, are approved

8 The resolutions introduced by Dr B R Shurly, delegate from the Section on Laryngology, Otology and Rhinology, regarding qualifications and standards for hospital inspection and the supply of these to all state, county and city government officials are fully covered by publications of the Council and such information is available on request made to the headquarters office of the American Medical Association in Chicago

J F HAGERTY
W A COOK

On motions duly seconded and carried, the first two sections of the report were adopted

Dr Abell moved that section 3 of the report referring to the resolution introduced by Dr G Henry Mundt Illinois be adopted The motion was seconded by Dr William H Ross, New York

Dr G Henry Mundt, Illinois, moved as a substitute motion that the resolution as introduced by him be adopted The substitute motion was seconded and carried after discussion by Drs R W Fouts, Nebraska John F Hagerty, New Jersey B F Bailey, Nebraska James E Paulin Jr, Section on Practice of Medicine, Irvin Abell, Kentucky William F Bowen, Kansas C S Gorsline, Michigan, W E Bannen, Wisconsin Virgil E Simpson, Kentucky, Charles B Wright, Trustee, Mather Pfeifferberger, Illinois E H Cary Texas Leonce J Kosminsky, Arkansas, and Horace Reed Oklahoma

On motions, duly seconded and carried, sections 4 5 6, 7 and 8 of the report were adopted

Dr Abell moved that the report be adopted as a whole with the exception of the third section, which was amended by the adoption of the resolution as introduced by Dr Mundt The motion was seconded by Dr Joseph F Smith, Wisconsin, and carried

Report of the Reference Committee on Miscellaneous Business

Dr H B Everett, Chairman presented a report of the Reference Committee on Miscellaneous Business and moved its adoption On motion made by Dr Charles H Goodrich New York and seconded by Dr Samuel P Mengel, Pennsylvania, the matter was referred back to the committee

Report of the Reference Committee on Amendments to the Constitution and By-Laws

Dr H H Shoulders, Chairman presented the following report

Three amendments to the Principles of Medical Ethics were referred to your committee for consideration They were all prepared by the Judicial Council and introduced by the Chairman Dr G E Follansbee, who came before the committee to give valid reasons for the adoption of each of these amendments

Your committee finds that the amendments do not add any new principles They all serve the purpose of facilitating the interpretation of the principles by the membership at large

Your committee cannot describe these amendments in language more brief than the amendments themselves

Your committee recommends the adoption of the amendments
Respectfully submitted

On motions of Dr Shoulders, duly seconded and carried, the report of the committee recommending the adoption of each amendment was adopted, and on separate motions, duly seconded and carried the sections of the Principles of Medical Ethics were amended in accordance with the report

Report of the Reference Committee on Reports of Board of Trustees and Secretary

Dr W F Braasch, Chairman, presented the following report

1 Report of Secretary Your committee notes with much satisfaction that there has been a very small net loss of Fellows enrolled in the American Medical Association for this year That this loss should be so small in spite of the continued financial difficulties which have seriously affected the medical profession during the past year shows beyond any doubt the great desire of the bulk of the profession to support organized medicine This fact might be used by secretaries of state and county medical associations as a stimulus to their efforts to increase membership

Your committee endorses the comments of the Secretary on the value of militant active county societies in our organization It should be emphasized that the county society is the backbone of medical organization and medical stability

We note a growing tendency on the part of the leaders of the medical profession to take a more active part in the affairs of organized medicine The strength of the state, as well as the county society, depends largely on active participation by its leaders

Your reference committee wishes to express its commendation of the earnest and sincere work of the Secretary and of the devotion rendered by him to this position in the service of medicine

2 Your committee believes that the Board of Trustees is to be congratulated on its excellent financial report in spite of present unfavorable economic conditions and the various readjustments that were found necessary in the number and the remuneration of its employees It is of interest to note that the net profit for the year was approximately only \$5,000 and that the total income was but little less than last year

THE JOURNAL In keeping with the action taken in all previous years, your committee commends the high character and the valuable influence that the Association maintains under the able management of its present editor Your committee is glad to note that the recent editorial policies have deviated somewhat from those of the past in that suggestions previously made by the House of Delegates have been followed to an increasing extent during the past year, in regard to devoting more attention to matters of economic interest It seems to your committee that the high standard of THE JOURNAL has in no way suffered as a result of such action

While we agree that the main object of THE JOURNAL is in the field of medical science, nevertheless economic problems of fundamental importance are constantly arising which should be discussed and analyzed so that the medical profession might be given at least an abstract of current developments Your committee believes that this field merits more attention in the columns of THE JOURNAL and that such articles should be displayed so as to be easily assimilated by the general profession

Your reference committee wishes to call attention particularly to the foreign correspondence in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, a feature that is unique since there is no other medical publication in the world which maintains similar correspondents in all the leading nations of the world This service has been of great value in keeping the American medical profession informed accurately of official and economic changes in other countries

3 Special Journals Your committee had noted with apprehension in previous years the constantly mounting cost of the special journals. Your committee is glad to note that the cost of publication of the special journals exceeded the income by only approximately \$10,000, which represented a marked decrease in the loss sustained in preceding years. The saving in the cost of the special articles has been brought about by more careful selection of illustrations and by closer scientific scrutiny on the part of the editorial boards of material submitted for publication.

Your committee notes with satisfaction that the loss incurred in the publication of *HYGEIA* amounted to only \$30,000. The indirect good done to the profession by this publication may not be generally appreciated, but it is worthy of our most active support. It is of interest to note that only 14,000 physicians in the United States were subscribers to *HYGEIA* last year. A plea should be made that every physician subscribe to at least one copy, which might be found in his waiting room if not in his library.

4 QUARTERLY CUMULATIVE INDEX MEDICUS Your committee recommends the continued publication of the *QUARTERLY CUMULATIVE INDEX MEDICUS* and is well aware of the good it is doing. In view of the fact, however, that it is being consulted by so many varied interests other than those strictly related to the profession, one wonders whether the cost of its publication might not be shared by other agencies. Furthermore, we hope that the loss incurred in its publication, which was approximately \$44,000 in the past year, may in some way be lessened in the future. Such a publication for the advancement of scientific medicine might well be considered worthy of endowment by those interested in furthering medical progress.

5 Council on Pharmacy and Chemistry Your committee heartily endorses the ever increasing efficiency and importance of the work done by the Council on Pharmacy and Chemistry, as well as that of the chemical laboratory. We fear that many members of the Association fail to appreciate the important bearing this work has on the progress of the medical profession. We believe that this work should receive continued and unstinted support.

In view of the current economic stress, your reference committee suggests the possibility of a joint study by the Council on Pharmacy and Chemistry and the Bureau of Medical Economics of the costs of proprietary and other remedies employed by the medical profession in the diagnosis and treatment of disease. In many instances the exorbitant price has been a serious burden on the patient.

6 Council on Physical Therapy Your committee wishes to commend the splendid work done by the Council on Physical Therapy. We are impressed with the care and thoroughness of its investigations and the good it is doing. The Council has been of great help to the medical profession in preventing the exploitation of physical methods and of apparatus that are of doubtful value. Its efforts to educate the profession by means of exhibits and demonstrations as well as in regulating and controlling manufacturers, are of fundamental importance and deserve great praise. It is to be hoped that the state associations will take full advantage of the various opportunities offered by the Council to augment our knowledge of physical therapy.

Your reference committee would also recommend increased attention by the Council to the problems in physical therapy arising in the practice of the physician.

7 Bureau of Exhibits The development of scientific exhibits in recent years has been one of the most interesting phases of medical progress. Its educational value is being appreciated by the general profession. As a result of the stimulus given by scientific exhibits at the Association meetings, similar exhibits have been developed at the meetings of several state associations. In many of the sections the Scientific Exhibit has come to be regarded as the pivotal feature of the program, the papers read being more or less of an explanatory and supporting nature.

The Bureau also deserves much praise for the excellent exhibit shown at the Century of Progress exposition in Chicago. Your reference committee wishes to suggest to the House of Delegates that it express its appreciation to Dr. D. Chester Brown, retiring member of the Board of Trustees who has

been for many years chairman of the Committee on Scientific Exhibit.

8 Committee on Foods Too much praise cannot be given for the development of the work of the Committee on Foods. Its importance is being widely recognized and its recommendations are being adopted not alone by members of the Association but by the public. Its value as a protection to public health is generally realized and it is rapidly becoming one of the more important activities of the Association. We note with interest its rapid growth and extension into associated fields, as described in the report.

This is one of the necessary functions performed by the American Medical Association until the public generally and the government shall recognize the necessity for such a service on a public basis and assume this liability by legislative enactment.

9 Radio Broadcasting The far reaching influence of radio broadcasting on medical subjects on public thought is worthy of continued commendation and unlimited support. The pity is, however, that the radio activity on matters of public health and of sickness is not all under the control of the Association.

Your committee wishes to express the appreciation of the American Medical Association to the radio broadcasting chains for offering their facilities and expresses the hope that they will continue to afford such facilities to the Association in the future. At the same time your committee would condemn the increased broadcasting of unestablished remedies directly to the public and urge further activities on the part of the Board of Trustees leading to some type of control over this evil.

10 Field Secretary Attention has been repeatedly called by the House of Delegates to the desirability of bringing the central organization of the Association in closer contact with the various activities of the constituent societies. Committees of previous years believed that closer cooperation between the state societies and representatives from the Association headquarters would be of mutual benefit. At the meeting of last year your committee asked that the Board of Trustees consider the advisability of appointing a field secretary.

Your committee appreciates that the decision of the Board of Trustees to the effect that it would be inadvisable to take final action in the appointment of a field secretary at the present time is based on careful consideration.

However, these suggestions have resulted in bringing about a much more intimate relationship between the officers of the Association and the constituent state organizations than had previously existed and, as a result, has added to the loyalty and interest of the profession in the work of the Association.

Your committee notes and approves the fact that officers of the Association and the directors of the different bureaus have extended the work to county and state societies and other organizations, making a total of 500 addresses during the past year.

Although many of the state associations have developed into strong, active organizations nevertheless there are some state societies that are comparatively inadequately organized. In confirmation one reads in the report of the Bureau of Legal Medicine and Legislation of this year that in an increasing number of states the cults have scored heavily during the year 1933.

In the opinion of many delegates, particularly those representing some of the smaller and more sparsely settled states even further support from the Association headquarters would be desirable.

The possibility suggests itself of sending some representative of the central office who has had experience in the ways and means of certain fields such as legislative activities for example to study the problems involved and give such counsel as may be indicated.

Another method suggests itself whereby the activities of the Association headquarters might be brought in closer contact with the constituent societies. Many of the members of the House of Delegates have expressed the desire of more active and continued contact with the central office. With the adjournment of the House official relationship of the Delegates to the Association practically ceases. While it is realized that the obstacles in the way of calling an interim session are many nevertheless in many quarters the desirability of so doing,

particularly in times of danger or of stress, has been expressed. It is true that monthly bulletins issued in recent years have helped to give us some information concerning current problems. Nevertheless, some means whereby the members of the House of Delegates might be kept in closer touch with the activities and the policies of the Association headquarters would be of great value.

Your committee would therefore suggest to the Board of Trustees the advisability of maintaining an informational service on social, medical and economic subjects to be sent monthly as a bulletin to members of the House of Delegates, the committee in charge of the bulletin to include the Chairman of the Board of Trustees, the Secretary of the Association, the Editor of THE JOURNAL, the Speaker of the House of Delegates, and the directors of the Bureau of Legal Medical Legislation and the Bureau of Medical Economics, this bulletin to be sent monthly to all members of the House of Delegates and alternates regularly certified by the state medical societies.

Respectfully submitted

W F BRAASCH, Chairman
A J BEDELL
S P MENGEL
C J WHALEN
J B HARRIS

On motions of Dr. Braasch, duly seconded and carried, each of the ten sections of the report was adopted.

An amendment to the tenth section of the report that the representatives of the sections be included with the delegates from states was adopted on motion of Dr. Arthur J. Bedell, New York, seconded by Dr. Charles J. Whalen, Illinois, and carried.

The report was adopted as a whole, on motion of Dr. Braasch, seconded by Dr. Mather Pfeifferberger, Illinois, and carried.

Report of the Judicial Council

Dr. George Edward Follansbee, Chairman, presented the following report:

A resolution introduced by Dr. Charles J. Whalen, Illinois, calls attention to a recent action by the Medical Service Board of the American College of Surgeons approved by its Board of Regents, advocating and publicizing a procedure for furnishing medical and hospital care for certain classes of the population. No consideration appears to have been given to policies or procedure previously adopted by the American Medical Association, of which the Board of Regents are members. The American Medical Association is the one organization representing the entire body of physicians constituting the medical profession and by virtue of that fact is the only organization qualified to speak for the varying interests and ideas of the profession as a whole.

Recurring proposals concerning the entire practice of medicine from small sections of the profession without due regard to the policies of the entire profession as represented by the American Medical Association when presented to the public through other channels than the representative body are confusing to the public mind, are harmful to the profession and give aid and assistance to those bodies and individuals attempting to revolutionize medical practice.

The Judicial Council therefore recommends the adoption of the resolution as follows:

WHEREAS The American Medical Association including 100,000 physicians is the only democratic body representing the organized profession of this country through delegates regularly elected through county and state medical societies and

WHEREAS Other medical organizations and groups representing selected groups of specialists have from time to time issued pronouncements of policies in the field of medical economics and medical practice which do not represent the views of organized medicine and which purport to guide the medical profession and the public in the administration of medical affairs and

WHEREAS The House of Delegates of the American Medical Association has repeatedly condemned the issuing of such announcements and policies, which seriously embarrass the attempts of this organization to secure adequate care for the health of the American people and to protect the ideals of the medical profession and

WHEREAS The Board of Regents of the American College of Surgeons assembled in Chicago on Sunday June 10 promulgated a policy includ-

ing a prepayment plan for medical care restricted to so called approved hospitals to members of the staffs of such hospitals and to physicians acceptable to such staffs and

WHEREAS This action of the Board of Regents of the American College of Surgeons has been spread to the people of the United States through the public press on the opening day of the annual session of this House of Delegates therefore, be it

Resolved That the House of Delegates of the American Medical Association express its condemnation of such tactics and of this apparent attempt of the Board of Regents of the American College of Surgeons to dominate and control the nature of medical practice and be it further

Resolved That the House of Delegates request the Board of Trustees of the American Medical Association and the Judicial Council to ask the Board of Regents of the American College of Surgeons who are themselves members of the American Medical Association to explain the reasons for their action and to justify the attempt by this small group within a specialistic organization to legislate for all the medical profession of this country truly represented only by the American Medical Association

The report of the Judicial Council was adopted on motion of Dr. C. E. Humiston, Illinois, seconded by Dr. Albert Sorland, Section on Radiology, and carried unanimously.

Report of Reference Committee on Medical Economics

Dr. Frederic E. Sondern, Chairman, presented the following report:

1 Relative to the preamble and resolutions from the Section on Radiology, to wit:

WHEREAS It has been reported to the officers and members of the Section on Radiology of the American Medical Association that an intolerable condition exists between certain otherwise acceptable hospitals and their departments of radiology and

WHEREAS It is known that in several such hospitals the business management does the collective bargaining for x-ray business with staff members and outsiders to the detriment and the professional and financial loss of their staff roentgenologists and

WHEREAS Such practice is not only unethical but places such hospitals on a direct competitive medical practice basis with their respective roentgenologists which practice has been declared illegal in several states and

WHEREAS The practice of roentgenology or radiology is *ipso facto* the practice of medicine and cannot be separated therefrom be it therefore

Resolved That the House of Delegates of the American Medical Association go on record as opposing the exploitation of members of their own body in the manner outlined and be it further

Resolved That the House of Delegates of the American Medical Association in session duly assembled orders this resolution to be referred to the Council on Medical Education and Hospitals for the study and formulation of plans tending to the abatement of these highly unprofessional and obnoxious evils

Your committee considers the questions involved in these resolutions as being primarily ethical, rather than truly economic, and for this reason, while recognizing the evil, refrains from direct comment concerning them and recommends that the resolutions be referred to the Council on Medical Education and Hospitals for such action as its wisdom may indicate.

2 Relative to the preambles and resolution from the delegates from Indiana, to wit:

WHEREAS The legislative program for consideration of the next Congress will no doubt include prospective measures of social insurance, and

WHEREAS There are those who strongly favor including in this program the enactment of legislation creating some form of sickness insurance and

WHEREAS Ill advised legislation would harmfully affect the group of individuals to whom sickness insurance would be offered as well as the medical profession who would be required to provide the service and

WHEREAS A review of the history of the creation of sickness insurance as recently reported by the Bureau of Medical Economics of the American Medical Association indicates that the establishment of sickness insurance in Europe has frequently been actuated by political motives or economic purposes not giving full consideration of the best interests or wishes of the groups involved and in no country have the labor unions led a demand for sickness insurance and

WHEREAS In the present period of readjustment of the relationship of employer and employee under guidance of the state the demands of those who will peak for the body of millions of organized labor will be an all important factor in determining the shape any such legislation will take be it therefore

Resolved That the Board of Trustees be requested to appoint a committee whose duty it shall be at the proper time to contact the leaders of organized labor to learn the attitude of the group they represent and in conference with them to present the medical factors involved

Your committee realizes the importance of this resolution and would recommend that the Trustees be requested to contact at such time and in such manner as they deem proper with the leaders of those groups or bodies interested, to bring about a mutual understanding of their aims and desires not only from the point of view of the medical profession but also for the best interests of the patient with due regard to the basic beliefs and principles of medicine. It would likewise be well if the suitable committees of state societies would do the same.

3 Relative to the report of the Bureau of Medical Economics as printed in the Handbook on pages 50 to 60. Careful reading of this report convinces your committee of the efficient, thorough and unprejudiced manner in which it was made by the Bureau and your committee begs that you will commend these efforts in no uncertain terms. Almost every subject in the scope of medical economics has had consideration and as much reliable information as possible has been collected for your instruction and guidance. The matter of sickness insurance, state medicine and what not, call it what you will, is the burning question of the hour in the minds of many medical men. So much so is this the case that many a physician who has lost practice as well as income from savings during the five year period of depression looks eagerly to this House of Delegates for relief from his burdens, thinking that the delayed solution of the matter is the reason for his prolonged hardship. While the results of the many investigations and conclusions of the Bureau are available to every physician in *THE JOURNAL* and in the *BULLETIN* of the Association, it is the opinion of your committee that this information should be more definitely impressed on every physician of this country and your committee begs to suggest that you recommend this to the Trustees to be done in such ways as they deem best. While the Bureau endeavors to present each subject as fully as possible and to point out the reasons for various cautions, it has in no instance recommended a course of procedure. In consequence your committee has no recommendation but feels called on to express a warning that any effort on the part of organized medicine to solve these problems be predicated on the studies made or to be made by the Bureau. It is aptly stated, for example that while many lay interests have continued their activities in medical economics there is also a marked increase in proposals by groups within the profession to modify the established form of medical practice with the grave query whether such temporary expedients will bring greater benefits than those represented by the existing social values in medicine, which might be destroyed thereby. The matter of health insurance has been the subject of intensive study by the Bureau and the preliminary report in the April issue of the Association *BULLETIN* is particularly commendable. Details concerning the conditions at the beginning of sickness insurance, the changes in institutions and objectives, the medical service, the physician in sickness insurance and some general professional and social effects indicate the scope of the work and the information it conveys. This also should have the careful consideration of those who are giving thought to this matter. All said and done sickness insurance was the product of the brain of the German chancellor Bismarck, just half a century ago. Why? Not that adequate medical care should be provided for all, but because industry required the standardization of expense to make more certain the exact cost of production, the better to meet keen world competition. Bismarck won, but who lost? The doctor to be sure, but essentially the patient—study the figures published by your Bureau.

4 Relative to the report of the Bureau of Legal Medicine and Legislation. Your committee has read with interest the references to economic subjects under such captions as National Industrial Recovery Act, Federal Emergency Relief Administration and Federal Civil Works Administration and begs you to realize that the profession has accepted in view of the existing unparalleled economic situation, conditions of medical practice which should not and would not be tolerated under normal conditions.

5 Relative to the Report of the Judicial Council. Your committee would specially commend and invite your individual attention to that portion of the report dealing with medical economics on page 117 of the Handbook.

The statement is made that an organized and financial campaign for a socialized system of medical care to a large proportion of the population has crystallized into definite plans with the millions of certain foundations backing the effort. This is but one of several dangers to which attention is called in the report, which deserves your earnest study and every consideration.

The first section of the report was adopted on motion of Dr. Sondern, seconded by Dr. Grant C. Madill, and carried. An amendment offered by Dr. H. H. Shoulders, Tennessee, seconded by Dr. R. W. Fouts, Nebraska, that the matter be referred to the Judicial Council rather than to the Council on Medical Education and Hospitals, was lost.

The other four sections of the report were each adopted on motions of Dr. Sondern, duly seconded and carried.

On motion of Dr. Sondern, seconded by Dr. A. J. Scott Jr., California, and carried, the report was adopted as a whole.

The meeting recessed at 12 noon to reconvene at 2 p. m.

Tuesday Afternoon, June 12

The House of Delegates was called to order at 2 15 p. m. by the Speaker, Dr. F. C. Warnshuis.

Report of the Board of Trustees

Dr. J. H. J. Upham, Chairman, presented the following report:

1 At its meeting on Tuesday, the Board gave careful consideration to the resolution introduced by Dr. Joseph F. Smith, Wisconsin, relative to the composition of the Council on Physical Therapy. The Board would point out that in carrying on the work of that Council it has regularly maintained the original membership of the Council but has added thereto men to carry out special phases of the work, and that the Board will request the Council to pay increasing attention to the practical aspects of this work, adding to the membership of the Council accordingly.

2 Concerning the resolutions introduced by Dr. Clarence G. Toland, California. The Board is in intimate touch with plans already under way to make exhibits of importance in the Century of Progress permanent and will instruct the Bureau of Exhibits which it has established, to give special consideration to the dissemination of such exhibit material within the limits of the funds available for the purpose.

3 Relative to the resolution introduced by Dr. Horace Reed, Oklahoma, in behalf of the Oklahoma delegation, concerning the perfecting of a plan for the handling of liability insurance. The Board has appointed a committee to investigate the feasibility of the Association's instituting such a plan and will give consideration to the matter at a subsequent meeting.

Section 1 of the report was adopted on motion of Dr. Grant C. Madill, New York, seconded by Dr. William H. Ross, New York, and carried.

Dr. Arthur J. Bedell, New York, moved that the second section of the report be adopted. The motion was seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried.

On motion of Dr. William H. Mayer, Pennsylvania, seconded by Dr. Arthur J. Bedell, New York, and carried, the third section of the report was adopted.

Report of the Reference Committee on Hygiene and Public Health

Dr. W. F. Draper, Chairman, presented the following report:

1 Your committee approves the report of the Bureau of Health and Public Instruction included in the report of the Board of Trustees.

2 Relative to the resolution introduced by Dr. George W. Kosmak, New York.

WHEREAS It is now accepted that asphyxia plays a wider role than was formerly understood in death from other causes than mechanical suffocation and

WHEREAS The total toll of all asphyxial deaths is large and

WHEREAS It is known that many such deaths could be averted by prompt and proper use of modern measures and equipment for the relief of the element of asphyxia and

WHEREAS The Society for the Prevention of Asphyxial Death has been organized for the purpose of saving lives that would without up to date management be lost because of failure to relieve asphyxia and

WHEREAS That society has the approval of leaders in medical thought and administration therefore be it

Resolved That the Medical Society of the State of New York approves the aims and purposes of the Society for the Prevention of Asphyxial Death and instructs the delegates to the House of Delegates of the American Medical Association to sponsor a similar resolution at the next meeting of the American Medical Association

Your committee approves the principles embodied in the foregoing resolution and recommends that they be endorsed by the House of Delegates

3 Relative to the resolution introduced by Dr A J Scott Jr, California

WHEREAS The California Medical Association is informed that the American Medical Association through one of its departments favors the pasteurization of milk including certified raw milk and

WHEREAS The California Certified Milk Commissions has been embarrassed in this publication by the American Medical Association and

WHEREAS State organizations should receive complete support from the American Medical Association and

WHEREAS Certified raw milk as it is produced handled and inspected in California especially is safe raw milk now therefore be it

Resolved That the House of Delegates of the American Medical Association in the session at Cleveland request that the proper department be instructed to take such measures as may be necessary to restore the confidence in the use of certified raw milk

Your committee feels that the Board of Trustees may wish to refer this matter to the Committee on Foods, under whose jurisdiction it is believed that it would properly come

4 The following resolutions (containing amendment to send copies also to broadcasting companies) were drafted by your committee to cover the resolutions introduced by Dr C S Skaggs, Illinois, and Dr Orrin S Wightman, New York

WHEREAS The health of the citizens of the United States constitutes the greatest asset of the nation and the responsibility of conserving the health of the citizens and restoring them to health in times of illness reposes in the medical profession and

WHEREAS This responsibility is very great as is evidenced by the high educational and professional standards which physicians are required to meet in the various states of the Union before being permitted to diagnose disease and treat the sick and

WHEREAS Satisfactory and safe service of this type can only be rendered after a long and careful study of the causes and symptoms of disease and that these causes and symptoms can only be determined after an interview with and physical examination of the patient and

WHEREAS No rational or safe treatment can be decided on and carried out under circumstances other than those above set forth without danger to the life or health of the patient and

WHEREAS For many months past the radio broadcasting companies of the United States have through their various broadcasting stations permitted the exploitation of many drugs preparations patent medicines and so-called cures to the radio audiences of America and

WHEREAS It has been well established that some of the drugs preparations and patent medicines so exploited are dangerous in the hands of the layman others are of doubtful value and in practically all instances their value for the relief of the symptoms and conditions for which recommended have been overstated and are misleading to the public and

WHEREAS The symptoms and conditions for which these drugs preparations and patent medicines are recommended may be and frequently are indications of serious conditions calling for careful study on the part of a well qualified physician in order that a correct diagnosis may be made and the proper treatment instituted before the disease reaches an advanced stage and

WHEREAS Radio broadcasting is under the control of the Federal Radio Commission and the radio is being used to broadcast unsupportable claims and statements regarding a large number of drugs and preparations for the treatment of human ailments therefore be it

Resolved That the American Medical Association is opposed to the advertising recommending or in any way exploiting over the radio any preparations remedies medicines or appliances for the treatment of human ailments and that a copy of these resolutions be forwarded to the Federal Radio Commission with a request that in the interest of the health of the citizens of the United States they exercise their authority to discontinue such advertising over the radio Be it

Resolved That we favor a central national clearing bureau of the medical profession which shall act as a reference committee to confer and advise the broadcasting systems as to the propriety of accepting commercial programs advertising various proprietary and household remedie Be it further

Resolved That physicians use such influence with their cooperation in sending protests to the Federal Radio Commission and to broadcasting stations against misleading and unwarranted medical advertising Be it further

Resolved That copies of these resolutions be sent to all members of Congress and the United States Senate so that they shall be thoroughly informed of this menace to the health of our citizens and that they be urged to pass necessary laws to eliminate these dangers

Your committee approves these resolutions and recommends their adoption by the House of Delegates

W F DRAPER, Chairman
R L GREEN
R W FOUTS
E F CODY
JOHN W BURNS

On motions of Dr Draper, duly seconded and carried, the report was adopted section by section and as a whole

NEW BUSINESS

Resolution Opposing Plan to Make a State Controlled Commodity of the Practice of Medicine

Dr William H Seemann, Louisiana, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations

WHEREAS There is at present an attempt on the part of the board of administrators of the State Charity Hospital in the city of New Orleans to establish a \$9 500 000 addition to this hospital with Federal PWA funds and

WHEREAS They propose to liquidate this debt partly by the sale of state medical services therefore be it

Resolved That this House of Delegates of the American Medical Association go on record as being opposed to any such plan that directly or indirectly makes a state controlled commodity of the practice of medicine

Resolutions Authorizing Judicial Council to Make Investigations of Ethical Practices of Institutions

Dr E G Wood, Tennessee, presented the following resolutions which were referred to the Judicial Council

WHEREAS The principles of the Code of Ethics of the American Medical Association enjoins on institutions and organizations to observe the same principles as individual practitioners and

WHEREAS It is of the most vital importance to the public and to the medical profession that the principles of the Code of Ethics be observed by institutions organizations and individuals and

WHEREAS The Judicial Council of the American Medical Association has discretionary powers (conferred in chapter IX section I of the By Laws) to investigate practices in any community but is without the machinery and finances necessary for such investigations therefore be it

Resolved That the Judicial Council be directed to exercise its discretionary powers to make investigations of ethical practices of institutions wherever in its opinion such investigations should be made Be it further

Resolved That the Board of Trustees is requested to appropriate funds in such amounts as are necessary to enable the Judicial Council to set up and finance an organization for making such investigations under rules and regulations prescribed by the Council Be it further

Resolved That in the event an institution is found to be engaging in practices which are unethical the authorities of the institution shall first be so advised and given a reasonable time in which to alter its practices and in the event practices are not altered so as to conform to the Principles of the Code of Ethics the approval of such an institution shall be stricken from the lists of approved institutions by the American Medical Association The state and local medical societies of the state in which such an institution is located shall be notified by the Council of the action taken also the action shall be published in the official publications of the American Medical Association

Resolutions on Therapeutics in Diseases of Children

Dr Arthur C Morgan, Pennsylvania, on behalf of Dr Isaac A Abt Section on Pediatrics, presented the following resolutions, which were referred to the Reference Committee on Hygiene and Public Health

WHEREAS Therapeutics in diseases of infants and children constitutes an important and much neglected phase of pediatric practice and

WHEREAS Those remedial agents prescribed by the profession official in the United States Pharmacopoeia and National Formulary V are employed extensively in treating disease in infants and children and

WHEREAS The acceptance of new drugs and the deletion of remedies at present official in the Pharmacopoeia and National Formulary concerns pediatricians as well as the general practitioner who treats infants and children and

WHEREAS There is a strong tendency to undermine official remedies including those of pediatric importance and therapeutic usefulness by

proprietary remedies through clever advertising exploitation and salesmanship therefore be it

Resolved That the Philadelphia Pediatric Society take the initiative in urging the House of Delegates of the American Medical Association through its proper channels to suggest to the officers of the Pharmacopeal Convention 1930 and to the officers of the National Formulary Convention of 1930 the appointment of a representative group of pediatricians whose function shall be to suggest and advise those remedial agents (drugs and preparations of pediatric importance and therapeutic necessity) to be deleted retained and added to both the Pharmacopeia and the National Formulary who will cooperate with all present committees of the Pharmacopeia and National Formulary in furthering the work for revision Be it further

Resolved That the suggestion of average doses for the periods of infancy and of preschool and school ages be included in both texts as has been carried out previously with Pharmacopeal and National Formulary remedies in adults and that application be filed with the Committee of Credentials of the Pharmacopeal Convention and the National Formulary for a permanent seat as delegates to the convention for 1940

Resolution Requesting Appointment of Committee to Investigate Control of Patents on Devices

Dr George Blumer, Connecticut, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations

WHEREAS The number of patents covering products and devices used in the practice of medicine for the prevention of disease and for the care of the public health has multiplied greatly in recent years and

WHEREAS These patents are being administered under various types of control by universities foundations institutions and special committees and

WHEREAS The Principles of Ethics of the American Medical Association indicate the desirability that all such patents shall be given freely for the benefit of the public and

WHEREAS Changing conditions indicate a desirability for the formulation of a proper system of control of such patents for the benefit of the medical profession and the public therefore be it

Resolved That the House of Delegates request the Board of Trustees to appoint a committee to make a comprehensive study of this situation and report to the House of Delegates the situation existing and suitable recommendations for a plan of control Furthermore that the Board of Trustees appropriate such funds as may be necessary to carry out such a study as promptly and as completely as possible because of the pressing character of the situation

Resolutions Protesting Against Activities of Government Hospitals Beyond Purposes for Which They Were Created

Dr Henry C Macatee, District of Columbia, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations

WHEREAS This House of Delegates at the session held in Milwaukee in 1933 endorsed in principle the Minority Report of the Committee on the Costs of Medical Care and

WHEREAS That report defined the extent to which the federal government should engage in the practice of medicine through its various categories of medical personnel and

WHEREAS The Medical Society of the District of Columbia through its Committee on Medical Economics has found that the medical employees of the United States government in the District of Columbia are required to render medical care in many cases and under many circumstances not contemplated by the law creating the medical agencies involved such as the common practice of cabinet officers senators representatives and others high in official life to enter governmental hospitals and receive medical treatment without charge at the expense of the tax paying people of the United States the admission to government hospitals for free hospitalization and free medical care of the domestic servants and other employees and their families of individuals in public life and in active military and naval service and the maintenance of dispensaries or so called clinics in the capitol the Senate and House office buildings and in the following government departments and bureaus Agriculture Bureau of Engraving and Printing Commerce Interior Justice Labor Navy State Treasury War and so on the medical service rendered free in which dispensaries goes far beyond the requirements of first aid for which they were created and

WHEREAS The Medical Society of the District of Columbia in common with the other residents of the national capital has no means of making effective its protests against these unjust practices through the power of the franchise therefore be it

Resolved That the House of Delegates of the American Medical Association endorse in principle the report of the Medical Society of the District of Columbia on the subject of hospitals and dispensaries maintained by the United States government in the District of Columbia and the protest of the said society against the extension of the activities of these agencies beyond the legitimate purposes for which they were created and be it

Resolved That the House of Delegates recommend that the constituent state associations take such action as may so influence their representatives in Congress that the taxpayers of the country may be relieved of

the unjustified expenditure of public funds herein set forth and that the protest of the medical profession of the District of Columbia may be supported by the voting strength of the national profession

Resolution on the Recognition of Specialties for Certification by the American Medical Association

Dr Descum C McKenney, Section on Gastro-Enterology and Proctology, presented the following resolution, which was referred to the Reference Committee on Medical Education

WHEREAS The specialties of gastroenterology and proctology are recognized by the American Medical Association by an active section of the Association and

WHEREAS Nearly 2 000 Fellows of the Association are limiting their practices to either proctology or gastroenterology and

WHEREAS The primary thought behind the certification of specialties is the protection of the public against those who are setting themselves up as specialists in these specialties and

WHEREAS There should be an official and authentic check up and regulation of those Fellows who are practicing these specialties and

WHEREAS The omission of these two specialties from the list of specialties now recognized for certification by the Council on Medical Education and Hospitals will impede the efforts of ethical specialists in these fields of medicine in their battle against quacks charlatans and irregulars who are holding themselves up as specialists be it

Resolved That the specialties of gastroenterology and proctology as now recognized by the established section on these specialties be added to the list of specialties in medicine and surgery to be recognized for certification by the Council on Medical Education and Hospitals of the American Medical Association

Resolution on Irregularities in Investigation and Prosecution of Sales of Impure Foods and Drugs

Dr John F Hagerty New Jersey, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations

WHEREAS The Medical Society of New Jersey has learned of many irregularities in the investigation and prosecution of sales of impure foods and drugs be it

Resolved That the delegates to the American Medical Association be urged to bring this matter to the attention of the Association at its annual meeting urging congressional investigations for the purpose of correcting these evils which constitute a danger and menace to the public health

Resolutions on the Crisis of Organized Medicine

Dr John F Hagerty, New Jersey, presented the following resolutions, which were referred to the Reference Committee on Medical Economics

WHEREAS The Medical Society of New Jersey assembled at its one hundred and sixty eighth annual meeting at Atlantic City N J through its house of delegates has approved the recommendation contained in the annual address of the president Dr Frederic J Quigley relative to the crisis of organized medicine and

WHEREAS This society feels that unless the parent body of organized medicine the American Medical Association immediately assumes the leadership to meet the greatest threat that has ever been made to American medicine to wit the menace of control of medicine by the state be it

Resolved That the delegates representing the Medical Society of New Jersey in the House of Delegates of the American Medical Association be directed to call attention of the House of Delegates to our concept concerning the imminent crisis now upon us and be it further

Resolved That our delegates be requested to use their best efforts to the end that a plan and scope to meet this emergency be forthwith promulgated through the channels of the American Medical Association

Resolution on Contraceptive Devices and Methods

Dr L J Hirschman, Michigan, for Dr Arthur H Curtis, Section on Obstetrics, Gynecology and Abdominal Surgery, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health

WHEREAS Innumerable devices chemical substances and techniques are being promoted to the public for the purposes of contraception and

WHEREAS Members of the medical profession are constantly asked by the public to advise them relative to scientific efficacy of such materials and methods therefore be it

Resolved That the Board of Trustees of the American Medical Association request the Council on Pharmacy and Chemistry Council on Physical Therapy the Bureau of Investigation and a committee of five to be selected by the Section on Obstetrics Gynecology and Abdominal Surgery to investigate the virtues and dangers of the various materials and methods and to publish its report when complete in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

Resolution on Birth Control

Dr William Ellingwood, Maine, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health

Resolved By the House of Delegates of the Maine Medical Association assembled in regular annual session at Bangor Maine on May 28, 1934

First that we approve the principle of birth control

Second that we approve of Senate Bill 1842 and of House Bill 5978 now pending in the Congress of the United States and that we would amend sections 211 and 245 of the U S Penal Code and sections 311 and 312 which affect the territories and districts of the United States by adding the following paragraph to each section

The provisions of this section shall not be construed to apply to any book or information relating to the prevention of conception or article instrument substance drug medicine or thing designed adapted or intended for the prevention of conception for use

1 By any physician legally licensed to practice medicine in any state territory or the District of Columbia or by his direction or prescription,

2 By any medical college legally chartered under the laws of any state territory or the District of Columbia

3 By any druggist in filling any prescription of a licensed physician

4 By any hospital or clinic licensed in any state territory, or District of Columbia

N B—Passage of the foregoing by our delegates means that our delegate to the A M A meeting is instructed by inference to support similar legislation, when it comes before the national body

Report of Council on Scientific Assembly

Dr Olin West, Secretary, presented the following report
The Council on Scientific Assembly at a meeting held on June 12, 1934, was favorably disposed toward a joint scientific meeting of the Canadian Medical Association and the American Medical Association

The report of the Council was adopted on motion of Dr Arthur C Morgan, Pennsylvania, duly seconded and carried

Resolution on Establishment of Standards, Ratings and Inspections of Training Schools in Physical Therapy

Dr Olin West Secretary, presented the following communication and resolution received by him from the American Physiotherapy Association, which were referred to the Reference Committee on Medical Education

My dear Dr West

The enclosed resolution has been drawn up by a committee made up of representatives of the Council on Physical Therapy and of the American Physiotherapy Association The Executive Committee of the American Physiotherapy Association urgently request that the resolution be presented to the House of Delegates at the annual meeting of the American Medical Association and that members be made fully acquainted with the purpose for its adoption

Since the war, orthopedic surgeons have used the physiotherapy technician in large measure to aid in their reconstruction work The organization of technicians has been striving to keep its standards high and we feel it is essential at this time that high educational standards be established

The members of the American Physiotherapy Association, working only under supervision of the medical profession wish to place the matter of training schools in the hands of the American Medical Association

Copies of the resolution have been given to the two Chicago members of the House of Delegates Dr Reed and Dr Humiston who will give their support

Thank you for your attention to this

Very truly yours,

BESS B SEARLS, Secretary,

AMERICAN PHYSIOTHERAPY ASSOCIATION

WHEREAS There is a recognized demand for qualified professionally trained physical therapy technicians in the hospitals clinics crippled children's schools and physicians offices of this country and

WHEREAS The work of these technicians is under the direction of members of the medical profession and

WHEREAS The medical profession and the American Physiotherapy Association recognize the vital importance of establishing minimum standards of training and the inspection of training schools in physical therapy by a qualified and authoritative organization therefore be it

Resolved That the entire subject be left to the Board of Trustees of the American Medical Association with the request that it be given careful study and consideration, and if practical and feasible some plan for the establishment of standards ratings and inspections of training schools in physical therapy be effected providing that the expense of such inspection be borne by the school requesting the same

Executive Session—Tuesday Afternoon, June 12

The Speaker declared the House in executive session

Report of Special Committee

Dr Nathan B Van Etten, Chairman, read the following report of the Special Committee appointed to consider the resolution submitted to the House of Delegates from the delegates of the state of Michigan and a statement of the Board of Trustees concerning Sickness Insurance in the United States

The following resolution was submitted by delegates of the Michigan State Medical Society

WHEREAS There is substantial evidence that powerful forces and agencies are working toward the development of health insurance in the United States and

WHEREAS During the course of its studies of medical economic problems the Michigan State Medical Society after a conference with officials of the American Medical Association found it necessary to send a commission to England to inquire into the subject of health insurance and

WHEREAS The commission presented the following report—which has been printed in full in the *Journal of the Michigan State Medical Society*—and placed in printed form in the hands of all of the delegates of this House

WHEREAS The report of the commission raises certain grave questions concerning the policy of the officials of the American Medical Association toward health insurance and the effects of this policy on the practicing membership of the American Medical Association and

WHEREAS The report of the commission was transmitted to the Board of Trustees of the American Medical Association through the chairman in February 1934 and

WHEREAS The Michigan State Medical Society has received no word nor has it any other evidence that the Board of Trustees of the American Medical Association has considered or acted on the report transmitted in February 1934 therefore be it

Resolved That in order to avert a repetition in the United States of the disastrous consequences that attended the adoption of health insurance in England the Speaker of the House of Delegates of the American Medical Association appoint a committee to investigate and consider the policy of the Association toward health insurance and present a report to the House of Delegates

Your reference committee has reviewed with painstaking interest the report of the procedures of the commission of the Michigan State Medical Society, commends the efforts of the commission to study and digest an important social operation concerned with medical service in England applauds the sanity of its conclusion and its recorded opposition to the introduction into the United States of any system of health insurance now existing in any country in Europe because no system conforms at present with all of the policies adopted by the Michigan House of Delegates in July 1933, namely

1 Free choice of physician by the insured

2 Limitation of benefits to those of medical service

3 The control of medical service benefits by the profession

4 The exclusion of individuals or organizations that might engage in health insurance for profit

Your committee believes that their principles are basically sound and that they should be included within any further study of medical service to be adopted as the policy of organized medicine

Your committee regrets the criticisms of policy and sincerity of officials of the American Medical Association and the publicity given to them and finds that it was due to a misunderstanding regarding information which failed to reach the delegates from Michigan This relates to the efforts of the Board of Trustees the Bureau of Medical Economics, the Secretary and the Editor to study continuously all forms of social experiment affecting the practice of medicine

Your committee believes in the sincerity of the officials of the American Medical Association in promoting free access or any member of the Association to all of the files and completed records in which he may be interested

The Chairman of the Board of Trustees presented the following statement at an earlier session of the House

Since 1912, when the British government, through the action initiated by Lloyd George, established a system of compulsory health insurance, this problem has been prominently before the House of Delegates and other official bodies of the American Medical Association As early as 1916, the House of Delegates requested the Board of Trustees to

undertake an investigation of social insurance in all its forms and to make suitable report to the House. The subject has been raised from time to time since that date. On every occasion on which the House of Delegates has officially considered the questions of compulsory health insurance and social insurance, as well as the entrance of the state into medical practice, it has reaffirmed the independence of medicine as a profession and it has always condemned any system whereby the state would in any way enter into the practice of medicine. In 1920, following the report of the committee appointed to study compulsory health insurance, the House of Delegates adopted a resolution strongly condemning all forms of compulsory health insurance.¹ It is a well known fact that voluntary insurance has always been the forerunner of compulsory insurance, and even the most ardent advocates of voluntary insurance admit that fact. The action of that House of Delegates has not been rescinded by any subsequent action taken by the House of Delegates.

As far as state medicine is concerned the House of Delegates in 1921 adopted a resolution approving and endorsing all activities and policies of the states directed to the prevention of disease, but opposing the state treatment of disease except for the delinquent and the defective." Again in 1922 the Association declared its opposition to all forms of state medicine because of the ultimate harm that would come thereby to the public weal through such form of medical practice.

The Judicial Council of the Association has repeatedly brought reports to this House of Delegates sustaining the same point of view, and all these reports of the Judicial Council have been accepted and approved by the House of Delegates.

Finally last year the House of Delegates unanimously approved in principle the Minority Report of the Committee on the Costs of Medical Care and urged that the Board of Trustees of the American Medical Association in cooperation with its constituent bodies conduct an intensive campaign to disseminate this point of view among the medical profession and the public, with a view to the maintenance of high ethical standards and the preservation of professional ideals.

Your Board of Trustees your executives and all the publications of this Association have done their utmost thus far to carry out the policies which you have established. Today we are confronted with an extraordinary situation of the utmost importance to the health and welfare of the American people and to the American medical profession. It is no secret that a considerable number of foreign nations have already established state systems of medical care and that an intensive campaign has been carried on in this country for many years, led by philanthropists, social workers, economists and various foundations to cause the American medical profession and the American people to accept a similar type of medical practice. In accordance with the mandate of this House of Delegates, all the facilities of the American Medical Association have been used to oppose this trend and the propaganda in support of it, which has been widely circulated and for which vast sums of money have been and are being expended by various interested parties. It is also now well known that the President of the United States, in a recent message, has come forth for the principle of social insurance, with special reference to old age pensions and unemployment insurance.

In 1930 the House of Delegates recommended to the Board of Trustees the establishment of a Bureau of Medical Economics in the headquarters office for the study of all these problems as they affect the medical profession. From time to time this Bureau has issued bulletins of the greatest importance, not only for the factual data which they present but also for the interpretation of medical economic trends. In accordance with a special request by the Board of Trustees, your Bureau of Medical Economics has prepared an extended statement of the conditions in relationship to state

medicine and compulsory insurance, as they exist in other nations. This statement was made available to all Fellows of the American Medical Association by publication in the BULLETIN of the Association for April 1934. In connection with the publication of these data and this critical analysis, the Bureau of Medical Economics has also drawn up a statement entitled *Sickness Insurance Problems in the United States*, which purports to be an interpretation of the data already referred to and which includes a presentation of twelve basic principles, which should be given most careful study in relationship to any recommendations that this House may care to make on this problem for the future. This statement will now be distributed to the House of Delegates.

There are manifestations of unrest in relationship to the economic situation among some of the component and constituent bodies of this association. On several occasions, communications have been made to the Board of Trustees and to the headquarters office, urging a change in the activities of the organization which would in effect demand a departure from the policies set down by this House of Delegates during the past eighteen years. The problem is before you. The opportunity is offered here this afternoon for an extensive discussion of the situation as it confronts the medical profession today. The Board of Trustees hopes that you will give it earnest and careful consideration. Only the House of Delegates has the power to define the policies that are to guide this Association in the coming years.

Your committee believes that this statement of the Chairman of the Board of Trustees briefly reviewing the history of the action of the House of Delegates during the past eighteen years sufficiently illuminates the sincere and deep concern of the American Medical Association regarding all social programs affecting the delivery of medical service.

The delegates have in their hands a pamphlet entitled "*Sickness Insurance Problems in the United States*" as presented by the Board of Trustees.

Your committee does not recommend any plan but has abstracted from the pamphlet the following principles and suggests that they be followed by all constituent bodies of the American Medical Association as bases for the conduct of any social experiments that may be contemplated by them.

First All features of medical service in any method of medical practice should be under the control of the medical profession. No other body or individual is legally or educationally equipped to exercise such control.

Second No third party must be permitted to come between the patient and his physician in any medical relation. All responsibility for the character of medical service must be borne by the profession.

Third Patients must have absolute freedom to choose a duly qualified doctor of medicine who will serve them from among all those qualified to practice and who are willing to give service.

Fourth The method of giving the service must retain a permanent confidential relation between the patient and a family physician. This relation must be the fundamental and dominating feature of any system.

Fifth All medical phases of all institutions involved in the medical service should be under professional control, it being understood that hospital service and medical service should be considered separately. These institutions are but expansions of the equipment of the physician. He is the only one whom the laws of all nations recognize as competent to use them in the delivery of service. The medical profession alone can determine the adequacy and character of such institutions. Their value depends on their operation according to medical standards.

Sixth However the cost of medical service may be distributed the immediate cost should be borne by the patient if able to pay at the time the service is rendered.

Seventh Medical service must have no connection with any cash benefits.

¹ Index and Digest Official Actions of American Medical Association p. 53

² Index and Digest Official Actions of American Medical Association p. 175

CLEVELAND SESSION

2201

Eighth Any form of medical service should include within its scope all qualified physicians of the locality covered by its operation who wish to give service under the conditions established

Ninth Systems for the relief of low income classes should be limited strictly to those below the comfort level

Tenth There should be no restrictions on treatment or prescribing not formulated and enforced by the organized medical profession

If it is determined in a community that some experiment to change or improve the method of administering medical service is desirable, observance of these principles will remove many of the "disturbing influences" from such an experiment. In all such experiments, attention must be sharply focused on the quality of medical service.

Such restrictions will undoubtedly lower the enthusiasm of many of the present advocates of such schemes. They remove the interest of the politician the commercial promoter and all those who consciously or unconsciously are seeking to achieve other objectives than better medical care for those unable to provide such care for themselves under present conditions. All these principles are directed toward protecting the character of the service to be given and all are directly designed to guard against abuses which experience shows are bound to arise when these principles are neglected. In most communities it will be found that comparatively few changes in the methods of administering medical care will be necessary. That type of medical practice which preserves the personal relationships between physician and patient, that maintains the practice of medicine as a profession, and that has withstood the test of centuries must be preserved for the best interests of both the public and the medical profession.

The report of the committee was adopted section by section and as a whole on motions of Dr Van Etten, duly seconded and carried, with the substitution of the words 'legally qualified Doctor of Medicine' for the word 'physician'.

Requests for Appointment of Standing Committee to Continue Study of Subject

A proposal was submitted by Dr J D Brook, Michigan, to the effect that a standing committee of seven from the House of Delegates, composed of men in active practice of medicine be appointed by the Speaker to continue the further study of the subject. This was referred to the Reference Committee on Medical Economics.

Press Committee

On motion of Dr H A Luce, Michigan, seconded by Speaker, was requested to appoint a press committee for the release of such information as the committee may deem proper relative to matters discussed in the executive session. The Speaker appointed the following press release committee: Drs Nathan B Van Etten, Frederic E Sondern and Morris Fishbein.

There ensued discussion by Dr Nathan B Van Etten New York, Dr H M Johnson Minnesota, Dr Frederic E Sondern New York, Dr Holman Taylor Texas, Dr J Newton Hunsberger, Pennsylvania, Dr W A Bates South Dakota, Dr Walter E Vest West Virginia, Dr William H Mayer, Pennsylvania, Dr H H Shoulders Tennessee, Dr Arthur C. Morgan Pennsylvania, Dr Joseph A Pettit, Board of Trustees, Dr R W Fouts Nebraska, Dr John F Hagerty New Jersey, Dr Crum Epler Colorado, Dr Virgil Simpson, Kentucky, Dr William D Johnson New York, Dr G Henry Mundt Illinois, Dr E H Cary Texas, Dr Morris Fishbein, Editor of THE JOURNAL, Dr Leonce J Kosminski, Arkansas, Dr Charles H Goodrich New York, Dr Felix J Underwood Mississippi, Dr George P Johnston Wyoming, Dr William D Chapman Illinois, Dr T B Throckmorton Section on Nervous and Mental Diseases, Dr William G Ricker Vermont, Dr Fred Moore Iowa, Dr Olin West, Secretary, and Dr Austin A Haven Board of Trustees.

Resolution on Communications to Delegates

Dr Arthur C Morgan, Pennsylvania presented the following resolution which was referred to the Reference Committee on Medical Economics

Resolved That it is the sense of this House of Delegates that the Secretary of the American Medical Association shall in his discretion communicate with the members of the house of delegates from the state society concerned when communications of criticism from the rank and file are received at the headquarters for friendly suggestion and recommendation

The House of Delegates adjourned from executive session into regular session

Report of the Reference Committee on Miscellaneous Business

Dr H B Everett, Chairman, presented the following report

On resolution introduced by Dr Vander Veer at the request of the House of Delegates of the Medical Society of the State of New York pertaining to administration of anesthetics, which was recommended for further action, your committee is of the opinion that, owing to the varying conditions which prevail in urban and rural districts, the matter in question deserves more careful study and survey than this committee can give at this time. We recommend that this resolution be referred to the Council on Medical Education and Hospitals for further study and report at a later time.

Respectfully submitted

H B EVERETT, Chairman
E N ROBERTS
J D COLT
G W WELLS
H A MILLER

On motion of Dr Everett, seconded by Dr Arthur J Bedell, New York and carried, the report was adopted

Report of the Judicial Council

Dr George Edward Follansbee, Chairman, presented the following report

1 Resolution from the House of Delegates of Oklahoma. This resolution provides that the American Medical Association adopt policies by which it shall not approve any hospital or other institution for any purpose unless and until it has been officially approved by the medical society of the county in which it is located.

The terms of this resolution are so broad and indefinite that the Judicial Council believes them to be impractical. It is also of the opinion that the question of approval or disapproval of the hospitals or other institutions of the country should be based on a uniform standard and appraisal rather than on such varying standards as would be the case if the appraisal were the function of the local medical society. Thus opinion is not changed by a provision in the resolution granting to a disapproved institution the right of appeal to the American Medical Association.

The Council is of the opinion that, so far as the Council on Medical Education and Hospitals goes in obtaining information and laying down the principles governing approval, its work is well done and not open to criticism. However, it may be advisable in establishing its standards for approval to extend its field of inquiries beyond the professional and economic features into the ethical as well.

For the foregoing reasons the Judicial Council disapproves the resolution.

2 Resolution presented by Dr Ben R McClellan Ohio. This resolution asks that renewed attention and emphasis be placed on an action taken by the House of Delegates in 1924. The Judicial Council recommends its adoption. The resolution is as follows:

WHEREAS There are occasional evidences of advertising publicity and propaganda by certain large clinics in violation of the proper ethical and professional restrictions placed on individual physicians therefore be it

Resolved By the House of Delegates of the American Medical Association at its Eighty Fifth Annual Session in Cleveland June 11 to 15 1934 that attention of the county medical societies be called and emphasis again be placed on the following declaration of policy and principle incorporated in resolutions adopted by this body in 1924:

1 Publicity by clinics hospitals sanatoriums and other semipublic medical institutions as to quality of work done implies unusual and

exceptional ability and efficiency on the part of their professional staffs and therefore is advertising of the medical men concerned. This type of advertising distinctly savors of quackery and is unethical.

2. Publicity by any such institution stating or implying that by reason of its exceptionally fine equipment and material resources, it is able to or does give the public better medical service than similar institutions are able or willing to render, is advertising for purposes of self aggrandizement. Statements of this type are frequently exaggerated and misleading and are detrimental to the best interests of the public of the institution concerned and of true medical progress. Publicity of this kind is unethical.

On motions of Dr. Follansbee, duly seconded and carried, the report of the Judicial Council was adopted section by section and as a whole.

Resolution on Fellowship, Containing Amendment to By-Laws

Dr. George Edward Follansbee, Chairman, Judicial Council, presented the following amendment to chapter XI, section 2, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws:

WHEREAS In chapter IX, section I of the By-Laws is the following provision: The judicial power of the Association shall be vested in the Judicial Council whose decision shall be final. This power shall extend to and include (1) all questions involving Fellowship in the Scientific Assembly or the obligation rights and privileges of Fellowship. Although the powers given are broad the Judicial Council in its opinion is compelled by the by-law chapter XI, section 2 to do injustice to a few physicians not contemplated when this by-law was amended in 1930.

This by-law by requiring that an applicant for Fellowship must have graduated from a recognized school bars from Fellowship a few men who have attained prominence in medicine and against whom no disqualification exists except their unfortunate matriculation in a substandard school in most if not all cases due to ignorance. Many graduates of nonrecognized schools are Fellows having become such before the amendment barring such graduates was made. Should such Fellows Fellowship terminate temporarily for any cause under the by-law he cannot again be admitted. Therefore be it

Resolved That the By-Laws Chapter XI, section 2 be amended by adding at the end of the section: In exceptional cases members holding a degree equal in requirements to that of M.D. but not graduated from a recognized school who formerly were Fellows or who have established a high standard of professional attainment may be admitted as Fellows by the Judicial Council if in their judgment such action is desirable.

The House recessed at 5:20 p.m., to meet at 1 p.m., Thursday, June 14.

Third Meeting—Thursday Afternoon, June 14

The House of Delegates was called to order at 1 p.m. by the Speaker, Dr. F. C. Warnshuis.

Report of the Reference Committee on Credentials

Dr. J. D. Brook, Chairman, reported that 165 delegates had presented proper credentials and moved that the report of the committee be adopted. The motion was seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried.

Roll Call

Dr. Olin West, Secretary, called the roll and announced that more than a quorum of the House had responded.

Report of the Reference Committee on Credentials

Dr. J. D. Brook, Chairman, reported that an additional delegate had deposited credentials, making the total registration 166. The Speaker announced that, there being no objection, the report would be received.

Report of Judicial Council

Dr. Follansbee, Chairman, presented the following report: The resolutions introduced by Dr. E. G. Wood, Tennessee, in effect, urge the Judicial Council to use the discretionary power to investigate general professional conditions in a community, conferred on it by the Constitution and By-Laws, in the investigation of hospitals and other institutions and to use such powers of warning, discipline and publicity as it possesses to force such hospitals and institutions as it finds guilty of unethical practices to discontinue them. They also request the Board of Trustees to finance such organizations as may be necessary to carry out the provisions of the resolutions.

It seems to the Judicial Council that the field which it probably would be necessary to cover is so extensive as to

make the proposal unpractical on account of the time and expense involved. It also believes that the Council would be called on in cases of factional or trivial disputes which should be settled by the county society and brought to the Judicial Council only on appeal from the state association.

The Council recognizes that the maintenance of ethical practices in hospitals approved for intern training is important in the education of the young doctors about to enter private practice but believes that other methods of approaching the desired end should be tried before such a time consuming and expensive procedure is established.

The resolutions are therefore disapproved.

Respectfully submitted

On motion of Dr. Ralph A. Fenton, Oregon, seconded by Dr. A. A. Walker, Alabama, and carried after discussion by Dr. H. H. Shoulders, Tennessee, the report of the Judicial Council was adopted.

Report of the Reference Committee on Medical Education

Dr. Irvin Abell, Chairman, presented the following report:

1. The resolution regarding the request for the establishment of standards, ratings and inspections of training schools in physical therapy is approved and referred to the Board of Trustees.

2. The resolution introduced by Dr. L. J. Hirschman, Michigan, and Dr. D. C. McKenney, Section on Gastro-Enterology and Proctology, on the recognition of specialties for certification by the American Medical Association, was considered by your committee, to the deliberations of which many members of the Section on Gastro-Enterology and Proctology and members of the Council on Medical Education contributed. In view of the fact that the American Medical Association recognized and provided a Section on Gastro-Enterology and Proctology, now in existence for sixteen years, this committee approves of the resolution and recommends that it be referred to the Board of Trustees and Council on Medical Education and Hospitals for determination of the methods of examination and certification in these specialties.

Respectfully submitted

IRVIN ABELL, Chairman
J. W. AMESSE
J. F. HAGERTY
FRED MOORE
W. A. COOK

On motions of Dr. Abell, duly seconded and carried, the report was adopted section by section and as a whole.

Report of the Reference Committee on Legislation and Public Relations

Dr. C. E. Mongan, Chairman, presented the following report:

1. In regard to the resolution introduced by Dr. John F. Hagerty on behalf of the Medical Society of the State of New Jersey relative to investigations and prosecutions of the sale of impure foods and drugs, the committee recommends that the matter covered by this resolution be referred to the Board of Trustees.

2. Concerning the resolutions presented by Henry C. Macatee, on behalf of the Medical Society of the District of Columbia: Your committee finds that the purport of the resolutions are in accord with the policies of the American Medical Association and it is recommended that this House of Delegates regard it essentially unfair to the tax-paying public and the medical profession for the government, federal, state or municipal, to extend free medical and hospital services to persons not legally entitled thereto.

3. Concerning the resolution offered by Dr. William H. Seemann, Louisiana, with reference to the proposed extension of service of the State Charity Hospital in the city of New Orleans by the use of federal PWA funds: Your committee finds that while the resolution is local in character, it involves a policy of national interest and concern. It is therefore recommended that this House of Delegates go on record as opposing the use of federal funds as a loan for the promotion of any enterprise the cost of which is to be eventually repaid through exploitation of the medical profession.

4 Your committee recommends the adoption of the resolution offered by Dr George Blumer, Connecticut with reference to patents concerning products and devices used in the practice of medicine

Respectfully submitted

C E MORGAN, Chairman
G C MADILL
C W WAGGONER
HOLMAN TAYLOR
JOSEPH F SMITH

The report was adopted section by section and as a whole, on motions of Dr Morgan, duly seconded and carried

Report of the Reference Committee on Hygiene and Public Health

Dr W F Draper, Chairman, presented the following report

1 Relative to the resolutions introduced by Dr A C Morgan, Pennsylvania, providing that the House of Delegates through its proper channels suggest to the officers of the U S Pharmacopeial Convention 1940 and the National Formulary Convention 1940 the appointment of a representative group of pediatricians to advise in regard to the retention and deletion of remedial agents of pediatric importance and necessity The Committee approves the resolutions and recommends their endorsement by the House of Delegates

2 The committee has ascertained that the work contemplated in the resolution, introduced by Drs E A Hines and J H Cannon, South Carolina, has received the approval of accredited representatives of the American Medical Association and the United States Public Health Service and that it has also received the endorsement of the Southern Medical Association, the American Laryngological, Rhinological and Otological associations and a number of state medical societies

In the opinion of your committee, this work is worthy of the support of the American Medical Association and the committee recommends the adoption of the resolution

3 Relative to the resolution introduced by Dr L J Hirschman, Michigan, which provides that the Board of Trustees of the American Medical Association request the Council on Pharmacy and Chemistry, the Council on Physical Therapy, the Bureau of Investigation and a committee of five to be selected by the Section on Obstetrics, Gynecology and Abdominal Surgery to investigate the virtues and dangers of the various materials and methods used for contraception and to publish its report, when complete, in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION The committee begs to refer this resolution back to the House of Delegates without recommendation by the committee

4 Relative to the resolutions introduced by Dr J D Brook, Michigan, providing for the appointment of a special committee to study and report on the problem of birth control in all of its medical aspects, the committee recommends that the resolutions be not approved

W F DRAPER Chairman
R W FOUTS
J W BURNS
R L GREEN
E F CODY

On motion of Dr Draper, duly seconded and carried the report of the committee was adopted section by section

Dr Draper stated, on inquiry by the Speaker, that the committee had a resolution of the Maine Medical Association but that it was simply a resolution of that association for the information of its delegates, and the committee did not feel that it was called on to act on that resolution

On motion of Dr Draper seconded by Dr William H Mayer Pennsylvania and carried, the report of the committee was adopted as a whole

Report of the Reference Committee on Amendments to the Constitution and By-Laws

Dr H H Shoulders, Chairman, presented the following report

Concerning an amendment to the By-Laws regarding Fellowship introduced by Dr George Edward Follansbee Chairman

of the Judicial Council, the preamble of the resolution sets out the reasons for the adoption of the amendment

In the opinion of your committee, the adoption of this amendment will enable the Judicial Council to deal justly with applicants for Fellowship It will not admit to Fellowship any one who does not deserve it It will enable the Council to admit some who deserve Fellowship but to whom that relationship is denied on technical grounds only

Your committee recommends the adoption of the amendment

Respectfully submitted

H H SHOULDERS, Chairman

Dr Shoulders moved that the amendment to the By-Laws be adopted The motion was seconded by Dr J Newton Hunsberger, Pennsylvania, and carried

Report of the Reference Committee on Reapportionment of Delegates

Dr Olin West, Chairman, presented the following report

The present apportionment of delegates is on the basis of one delegate for each 800 members or fraction thereof Each

Number of Delegates Based on Different Ratios

State	Number of Members 4/1/34	Bases of Apportionment and Number of Delegates Under Each	775	800

For 15 Sections	15	15	15	15
TOTAL		172	168	

Total voting membership of House shall not exceed 175

constituent association is represented by at least one delegate irrespective of the number of members

The By-Laws specifically provide that the total membership of the House of Delegates shall not exceed 175 The total membership of the Association on April 1 as recorded in the office of the Secretary was 98041

An apportionment on the basis of one delegate for each 750 members would produce a total of 177 delegates, two more than are permitted by the By-Laws

On the basis of one delegate for each 775 members, the total membership of the House would be 172, which is one less than the present membership. On this basis, Pennsylvania and Texas would each gain one delegate, while Alabama, Illinois and North Carolina would each lose one delegate.

On the basis of one delegate for each 800 members, the total membership of the House would be 168. On this basis Alabama, Illinois, North Carolina, Oklahoma and Tennessee would each lose a delegate.

The committee recommends that the apportionment of delegates for the next three years be made on the basis of one delegate for each 775 members or fraction thereof. Each state medical association, irrespective of the number of members, no matter how small its membership may be, is entitled to one delegate. On this basis, the membership of the House will be 172.

Respectfully submitted

OLIN WEST, Chairman
F C WARNSHUIS
C B REED

On motion of Dr C B Reed, Illinois seconded by Dr J Newton Hunsberger, Pennsylvania, and carried, the report of the Reference Committee on Reapportionment of Delegates was adopted.

Report of the Reference Committee on Medical Economics

Dr Frederic E Sondern, Chairman, presented the following report:

1 Relative to the resolutions from the Medical Society of New Jersey, presented by Dr John F Hagerty, your committee recognizes fully the serious tenor of these resolutions and the urgent desire of the delegates from New Jersey to secure the complete cooperation of this House in the matter.

Your committee feels, however, that the report of the special committee accepted by this House covers fully the requests made and also that the endorsement of this House one year ago of the Minority Report of the Committee on the Costs of Medical Care must be kept in mind therewith.

2 Relative to the resolution presented by Dr A C Morgan, Pennsylvania, requesting the Secretary in his discretion to communicate with members of the House of Delegates from the state societies concerned when communications of criticism are received from the rank and file, your committee would commend this effort in the interest of understanding and harmony and believes that the matter may well be left to the discretion of the Secretary of the Association.

3 Relative to the resolution requesting the appointment of a standing committee of seven, your committee assumes that this resolution was prompted by the accepted report of the special committee and, therefore, deals with the matter of sickness insurance although this does not appear clearly in the resolution itself. Your committee is in complete sympathy with any effort that will aid in the clarification of this matter and in the finding of a concrete solution. It must be apparent to all that the Bureau of Medical Economics of the American Medical Association not only has every facility for the further study asked for but also has demonstrated its efficiency, thoroughness and impartiality in this regard. Your committee would recommend that if the Bureau of Medical Economics feels the need of an advisory committee of outstanding members of the Association, a request for the same to the Board of Trustees would have every consideration.

On motions of Dr Sondern, duly seconded and carried, the report of the committee was adopted section by section and as a whole.

Resolutions Referred Back to the House by the Reference Committee on Hygiene and Public Health

The Speaker presented to the House the resolution introduced by Dr L J Hirschman, Michigan, and the resolutions introduced by Dr J D Brool, Michigan, which had been referred to the Reference Committee on Hygiene and Public Health and referred back to the House by that reference committee without recommendation, and asked what the pleasure of the House was with respect to them.

Dr B F Bailey, Nebraska, moved that the resolutions be tabled. The motion was seconded by Dr Horace Reed, Oklahoma, and carried.

Report from the Section on Nervous and Mental Diseases

Dr Tom B Throckmorton, Section on Nervous and Mental Diseases, presented the following report:

A committee appointed by the Section on Nervous and Mental Diseases last year met with similar committees of the American Psychiatric Association and the American Neurological Association at a preliminary meeting in New York in December 1933 to consider the formation of a board of examiners in psychiatry and neurology for the purpose of certifying physicians in these respective branches of medicine. At this conjoint meeting, certain broad principles were laid down, the name decided on for the governing board was the American Board of Psychiatry and Neurology. It was the consensus that there should be equal representatives of neurology and psychiatry on the board of examiners and that the board should be composed of four members from the American Psychiatric Association, four members from the American Neurological Association, and two psychiatrists and two neurologists appointed by the Section on Nervous and Mental Diseases of the American Medical Association. It was also the consensus of the meeting that there should be drawn up by the Board of Psychiatry and Neurology separate qualifications for psychiatrists and for neurologists and that there should be separate examinations for applicants wishing to be certified in one or both of these specialties.

The American Psychiatric Association and the American Neurological Association through their respective Councils, later approved the formation of the American Board of Psychiatry and Neurology.

The committee from the Section on Nervous and Mental Diseases, in conjunction with committees appointed by the American Neurological and the American Psychiatric Associations, then proceeded to draw up recommendations for the guidance of the Board of Certification on Psychiatry and Neurology in establishing the requirements for such certification in these respective specialties.

As a result of these various deliberations on the part of the special committee appointed last year from the Section on Nervous and Mental Diseases, the committee from the American Psychiatric Association and the committee from the American Neurological Association, the following recommendations were adopted by the Section on Nervous and Mental Diseases:

1 That the Section on Nervous and Mental Diseases of the American Medical Association cooperate with the American Psychiatric Association and the American Neurological Association in the establishment of the American Board of Psychiatry and Neurology.

2 That four members of the section, two neurologists and two psychiatrists, be elected to serve on the board for terms of from one to four years that each year hereafter a member be elected to take the place of the retiring member, neurology and psychiatry being always equally represented.

On motion of Dr Throckmorton, seconded by Dr J Allen Jackson, Pennsylvania, and carried, the report was adopted.

Resolutions Registering Disapproval of Employment of Optometrists by Hospitals, from the Section on Ophthalmology

Dr Emory Hill, Section on Ophthalmology, presented the following resolutions, which were adopted on motion of Dr Hill, seconded by Drs W Albert Cook, Oklahoma, and G Henry Mundt, Illinois, and carried:

WHEREAS It has come to the attention of the officers of the Section on Ophthalmology that some hospitals employ optometrists to prescribe glasses and

WHEREAS The members of the section are convinced that this practice is not to the best interest of the patient and

WHEREAS The only reason for such an unprofessional method seems to be monetary reward to the hospital and

WHEREAS The younger ophthalmologists need practice in refraction which is best secured under the direction of skilful physicians devoting themselves to the treatment of diseases of the eye be it

Resolved That the Section on Ophthalmology of the American Medical Association hereby registers its disapproval of the employment of optometrists by hospitals and be it further

Resolved That the House of Delegates of the American Medical Association be urged to institute the necessary measures to stop this pernicious invasion of the practice of medicine

Resolution on the Definition of Blindness, from the Section on Ophthalmology

Dr Emory Hill, Section on Ophthalmology presented the following resolution, which was adopted on motion of Dr Hill, seconded by Dr Ralph A Fenton, Oregon, and carried

WHEREAS A committee was appointed by the Section on Ophthalmology of the American Medical Association in response to a request from the Department of Public Welfare of the State of Illinois for a definition of blindness in scientific terms that might be made statutory and

WHEREAS There are various grades of blindness which should be distinguished, therefore be it

Resolved That the following definitions for grades of blindness be accepted by the House of Delegates

Total Blindness is inability to perceive light lack of light perception The person who is totally blind cannot tell whether strong light falls on his eyes or whether they are in total darkness Light perception is vision such as one has when the eyelids are closed

Economic Blindness is absence of ability to do any kind of work industrial or otherwise for which sight is essential In general visual acuity of less than one tenth has been classed as economic blindness meaning that objects can be recognized only when brought within one tenth of the distance at which they can be recognized with standard vision Such vision in the better eye when corrected with the best possible glass would be recorded as less than 0.1 or 6/60 or 20/200 or as an equally disabling loss of the visual field

Vocational Blindness is impairment of the vision that makes it impossible for a person to do work at which he had previously earned a living He may still have vision enough to do some other kind of work that may yield him an adequate support Such vision in the better eye with the best possible correcting glass may vary from one tenth to one third that is from 0.1 or 6/60 or 20/200 to 0.3 or 6/18 or 20/60 depending on the vision required for the occupation previously followed

Educational Blindness is such loss of sight as makes it difficult dangerous or impossible to learn by the methods that are commonly used in schools This necessitates two types of schooling for such individuals namely sight saving classes and schools for the blind The requirement for admission to sight saving classes is vision in the better eye with the best possible correcting glass of less than 20/70 and more than 20/200

The requirement for admission to the school for the blind is vision in the better eye with the best possible correcting glass of 0.1 or 6/60 or 20/200 or less

Communication from the Session on Forensic Medicine of the Section on Miscellaneous Topics

The Secretary presented the following communication from the Session on Forensic Medicine of the Section on Miscellaneous Topics which on motion of Dr A A Walker Alabama seconded by Dr Fred Moore Iowa and carried, was referred to the Council on Scientific Assembly

On motion by Dr Harrison S Martland duly seconded and carried, it was voted that the session organize a committee for the purpose of acquainting the suitable authorities in the legal profession with the existence and reliability of the blood grouping tests so that statutes may be enacted authorizing courts to order individuals to submit to blood grouping tests when they are required, in those jurisdictions in which blood tests are not obligatory at present

On motion of Dr Oscar T Schultz Evanston, Ill seconded by Dr Harrison S Martland, Newark, N J, it was voted that the session, through the secretary express its appreciation to the proper officials of the American Medical Association for the privilege of having held this meeting of the necessity and advisability of future meetings of this session at other meetings of the Association and that a committee be appointed to study this question of the advisability of future meetings

Communications from the Catholic Medical Mission Board and from the Kentucky State Medical Association

The Secretary presented a communication from the Catholic Medical Mission Board requesting a meeting of doctors especially interested in the work of that board

The Secretary also presented a letter from Dr A T McCormack Secretary of the Kentucky State Medical Association inviting the House of Delegates of the American Medical Association to attend the unveiling of the plaque in honor of the pioneer physicians of Kentucky at Fort Harrod Harrodsburg Ky June 21

Dr Mather Pfeifferberger, Illinois, moved that the communication be accepted and placed on file and that the invitation be accepted The motion was seconded by Dr Randolph Winslow, Maryland, and carried

Resolution on Proper Medical Care

Dr Ralph Fenton at the request of Dr Joseph A Pettit, received the unanimous consent of the House to present the following resolution, which was adopted on a motion of Dr Fenton, seconded by Dr Arthur J Bedell, New York, and carried after discussion by Drs J Tate Mason, Section on Surgery, General and Abdominal, and Joseph A Pettit, Trustee

WHEREAS In accordance with the traditions governing the medical profession physicians have always given and still give first consideration to the health and welfare of their individual patients and

WHEREAS The introduction into the practice of medicine of the mass production methods employed in industry cannot fail to be detrimental to the health and welfare of the individual patient therefore be it

Resolved That whether definitely stated or not it is the position of the American Medical Association that all conditions or principles adopted by the Association concerning the position of the medical profession in any form of medical practice are set forth primarily in order to maintain such standards and safeguards as are essential to the maintenance of the best medical care and the protection of the health of all members of the community

ELECTION OF OFFICERS

Election of President-Elect

The Speaker called the attention of the delegates to the provision of the By-Laws limiting to three minutes all nominating speeches, and then called for nominations for the office of President-Elect of the American Medical Association

Dr A A Walker, Alabama, nominated for President-Elect Dr James S McLester Birmingham, Ala, and the nomination was seconded by Drs C A Grote, Alabama F Clifton Moor Florida W H Robey, Massachusetts, George Blumer, Connecticut, Guy W Wells Rhode Island, H B Everett, Tennessee, William G Ricker, Vermont J Tate Mason, Section on Surgery, General and Abdominal, and Irvin Abell, Kentucky

Dr Holman Taylor, Texas nominated Dr Hugh S Cumming, Washington, D C The nomination was seconded by Drs Carl Moll in behalf of the Michigan delegation, A R McComas, Missouri, Stanley H Osborn, Section on Preventive and Industrial Medicine and Public Health, John W Ames Colorado Burt R Shurly, Section on Laryngology, Otology and Rhinology Ralph A Fenton, Oregon, J Gurney Taylor, Wisconsin, Albert Soiland, Section on Radiology, and J P DeWitt Ohio

The Speaker declared the nominations closed and appointed as tellers Drs O S Wightman, New York, A J Scott Jr, California Vernon L Treynor Iowa J D Colt Sr, Kansas, and James Beebe, Delaware

The Secretary, at the request of the Speaker, announced that 156 delegates had been recorded as present and that 156 votes had been cast, of which Dr James S McLester, Birmingham, Ala, received 85 and Dr Hugh S Cumming, Washington, D C, 71

The Speaker declared Dr James S McLester, having received the majority of the votes cast, elected President-Elect of the American Medical Association

Election of Vice President

Dr Ben R McCellan, Ohio nominated for Vice President Dr George G Reimle Oakland, Calif, and the nomination was seconded by Dr Clarence G Toland California

Dr William R Molony California moved that the nominations be closed and the motion was seconded by Drs Arthur J Bedell New York and William H Mayer, Pennsylvania, and carried

On motion of Dr G Henry Mundt Illinois seconded by Dr Albert Soiland Section on Radiology, and carried, the Secretary cast the ballot of the House for Dr George G Reimle as Vice President for the ensuing year

Election of Secretary

Dr William H Mayer, Pennsylvania, nominated Dr Olin West Chicago to succeed himself as Secretary of the Ameri-

can Medical Association, and the nomination was seconded by Dr Orrin S Wightman, New York On motion of Dr E R Mulford, New Jersey, seconded by several and carried unanimously, the nominations were closed

On motion of Dr Albert Soiland, Section on Radiology, seconded by Dr Samuel P Mengel, Pennsylvania, and carried, the Speaker cast the ballot of the House for Dr Olm West as Secretary of the American Medical Association and declared Dr West elected Secretary for the ensuing year

Election of Treasurer

Dr J H J Upham, Chairman of the Board of Trustees, nominated for the office of Treasurer Dr Herman L Kretschmer, Chicago The nomination was seconded by Dr W F Braasch, Minnesota, and Dr H W E Walther, Section on Urology Dr Mather Pfeifferberger, Illinois, moved that the nominations be closed, and the motion was seconded by Dr O S Wightman, New York, and carried

Dr B F Bailey, Nebraska, moved that the Secretary be instructed to cast the ballot of the House of Delegates for Dr Herman L Kretschmer, Chicago, as Treasurer The motion was seconded by Dr A J Scott Jr, California, and carried, and the Secretary cast the vote of the House for Dr Herman L Kretschmer, Chicago, as Treasurer of the Association for the ensuing year and the Speaker declared Dr Kretschmer so elected

Election of Speaker of the House of Delegates

Dr Nathan B Van Etten Vice Speaker, took the chair and announced that the next order of business was the election of a Speaker of the House of Delegates

Dr C S Gorshine, Michigan, nominated for Speaker of the House of Delegates Dr F C Warnshuis, Grand Rapids, Mich The nomination was seconded by several, after which Dr J N Vander Veer New York moved that the nominations be closed, and the motion was seconded and carried

On motion of Dr Albert Soiland, Section on Radiology, seconded by Dr J Newton Hunsberger, Pennsylvania, and Dr Charles H Goodrich, New York and carried the Secretary cast the vote of the House for Dr F C Warnshuis to serve as Speaker of the House of Delegates for the next year, and Dr Van Etten declared Dr F C Warnshuis elected Speaker of the House of Delegates

Election of Vice Speaker of the House of Delegates

The Speaker resumed the chair and called for nominations for Vice Speaker of the House of Delegates

Dr Arthur J Bedell, New York, nominated Dr Nathan B Van Etten, New York, and the nomination was seconded by several Dr Thomas Farmer, New York moved that the nominations be closed, and the motion was seconded by Dr J Newton Hunsberger, Pennsylvania, and carried

On motion of Dr J D Brook, Michigan, seconded by Dr H B Everett, Tennessee, and carried, the Secretary cast the vote of the House for Dr Nathan B Van Etten as Vice Speaker of the House of Delegates, and the Speaker declared Dr Nathan B Van Etten elected to the office of Vice Speaker for the ensuing year

Election of Trustees

The Speaker declared the next order of business to be the election of a trustee for a term of five years to succeed Dr D Chester Brown, Danbury, Conn, whose term expired this year and who, according to the By-Laws, was not eligible for reelection

Dr E F Cody, Massachusetts, nominated Dr Roger I Lee, Boston and the nomination was seconded by several delegates Dr Arthur J Bedell, New York, moved that the nominations be closed, and the motion was seconded by Dr J W Burns, Texas, and carried

On motion of Dr John H O Shea, Washington, seconded by Dr Ralph A Fenton, Oregon, and carried the Secretary cast the ballot of the House for Dr Roger I Lee, Boston, to serve as a member of the Board of Trustees for a term of five years, and the Speaker declared Dr Roger I Lee so elected

The Speaker called for nominations for the office of Trustee to succeed Dr Allen H Bunce, Atlanta, Ga, whose term of office had expired

Dr C W Roberts, Georgia, nominated Dr Allen H Bunce, Atlanta, Ga, to succeed himself The nomination was seconded by several, after which, on motion of Dr H B Everett, Tennessee, seconded and carried, the nominations were closed

On motion of Dr H H Shoulders, Tennessee, seconded by Dr Leonce J Kosminsky, Arkansas, and carried, the Secretary cast the ballot of the House for Dr Allen H Bunce, Atlanta, Ga, to succeed himself as Trustee for a term of five years, and the Speaker declared Dr Allen H Bunce so elected

Address of President-Elect James S McLester

The Speaker introduced President-Elect James S McLester, who addressed the House as follows

When you raise a man suddenly to a great height it makes him a bit dizzy, and he doesn't know just what to say In raising me to a position of leadership in this, the greatest medical organization in the world, you have raised me to great heights indeed and I am warmly appreciative

I am also deeply conscious of a sense of obligation, and in my poor way I shall endeavor to fulfil this obligation properly

We live in a changing world All human relationships are being examined if not in actual process of readjustment, and this is especially true of that happy relationship which has existed for so many generations between doctor and patient We must see to it you and I, in these changing times that no violence is done that fine relationship

I have a great deal of faith, I am confident, and I say this after mature deliberation that for the physician of character and training the world will always find a suitable reward and a place, not a mere cog in a bureaucratic piece of machinery, but as a counselor who fills a human and a thoroughly personal relationship

In our efforts toward the realization of that, I pledge you the best there is in me

Nominations for Standing Committees

Dr Walter L Biering, President presented the following nominations for Standing Committees

Judicial Council Dr Emmett P North, St Louis, to succeed Dr James B Herrick, for a term ending in 1939

Council on Medical Education and Hospitals Dr Fred Moore, Des Moines, Iowa, to succeed Dr Emmett P North, for a term ending in 1941, Dr John H Musser, New Orleans, to succeed Dr James S McLester, who had been elected President-Elect, for a term ending in 1940

Council on Scientific Assembly Dr Irvin Abell, Louisville, Ky, to succeed himself, for a term ending in 1939, Dr Cyrus C Sturgis Ann Arbor, Mich, to fill the unexpired term of Dr John E Lane, deceased, for a term ending in 1936

On motion of Dr Arthur J Bedell, New York, seconded by Dr Thomas F Thornton, Iowa, and carried, the House confirmed the nominations

Election of Honorary, Affiliate and Associate Fellows

REPORT OF COUNCIL ON SCIENTIFIC ASSEMBLY

The Secretary presented the report of the Council on Scientific Assembly recommending the election of Dr Howard Atwood Kelly, Baltimore, to Honorary Fellowship Dr Randolph Winslow, Maryland, moved that the report be adopted The motion was seconded by Dr Irvin Abell, Kentucky, and carried

APPLICANTS FOR ASSOCIATE FELLOWSHIP FROM AMERICAN MEDICAL MISSIONARIES APPROVED BY THE JUDICIAL COUNCIL

Place of 1935 Annual Session

The Speaker announced that the next order of business was the selection of the place of the 1935 annual session and requested the Board of Trustees to present nominations.

Dr J H J Upham, Chairman, presented the following report of the Board of Trustees

Mr Speaker Members of the House

Within the actual prescribed time for the presentation of invitations for the place of meeting there was but one invitation received, that from Atlantic City. The Board of Trustees, according to your direction, has inspected the facilities of Atlantic City and finds that city abundantly able to take care of this meeting in 1935.

A little later than the prescribed time was received an invitation from the city of Chicago. The Board has investigated the facilities at Chicago and knows no one building that has the facilities for housing all the meetings of the Association. It gives the preference of its recommendation to Atlantic City for 1935.

Dr Walt P Conaway New Jersey, extended an invitation from Atlantic City, after which on motion of Dr James N Vander Veer New York, seconded by Dr Arthur C Morgan, Pennsylvania, and carried the Secretary cast the vote of the House of Delegates for Atlantic City as the place of meeting of the American Medical Association in 1935 and the Speaker declared that the House had selected Atlantic City for its 1935 session.

UNFINISHED BUSINESS

Vote of Appreciation

Dr James N Vander Veer, New York, moved that the House of Delegates extend the cordial thanks and appreciation of the members of the Association to all those who contributed to their pleasure, entertainment and comfort, and to the press of the country as well as of the city of Cleveland who rendered such splendid service to the Association. The motion was seconded by Dr J Newton Hunsberger, Pennsylvania, and carried.

Appreciation of Services of Dr D Chester Brown

Dr George Blumer, Connecticut, moved that the House of Delegates extend to Dr D Chester Brown, Danbury, Conn, who this year retired as a member of the Board of Trustees, a resolution of appreciation for his services. The motion was seconded by several and carried, and the Speaker conveyed to Dr Brown the appreciation of the House.

Dr Brown addressed the House as follows

Mr Speaker and Gentlemen of the House of Delegates

I think you are going to establish a very bad precedent if you are going to reward the services of your members of the Board of Trustees by calling them up and giving them special recognition, it is going to be something that will take a good deal of your time, because many of them deserve very much more recognition than I.

I take great pleasure in expressing to you at this time what the Board of Trustees has as an animating purpose throughout its deliberations. You elect them to represent you during the time that you are not in session, and having had seventeen years on the Board I want to state to you that a loyalty to this House animates the Board in every action it takes. You have no idea how extensive that is, how it follows through every action of the Board, and there is never at any time a desire to usurp the prerogatives of the House of Delegates.

It has been a great pleasure to me during these past seventeen years to have served you, and I thank you very much for this expression of your appreciation.

Invitation from Miami, Florida

Dr F Clifton Moor, Florida, gave notice that Miami, Fla, would extend an invitation to the Association to meet in Miami in 1936.

The House of Delegates adjourned sine die at 3 25 p m

(To be continued)

Association News

THE GOLF TOURNAMENT AT CLEVELAND

The twentieth annual tournament of the American Medical Golfing Association held at the Mayfield Country Club, Cleveland, June 11, was a great success, attracting a total of 185 players. Some of the leading scores were as follows:

J P Loudon Yakima	76-76-152
G R Love Oconomowoc	80-78-158
J L Lattimore Topeka	84-76-160
Mark Bach Milwaukee	81-81-162
R P Bell Cleveland	84-81-165
J A Johnson New York	78-87-165
L Mark Columbus	85-84-169

At the banquet which lasted until the small hours of the morning prizes were awarded and Dr Charles Lukens of Toledo was elected president of the American Medical Golfing

Association for the ensuing year, Drs Charles H Henninger, Pittsburgh, and John B Morgan, Cleveland, vice presidents, and Dr Homer K Nicoll, Chicago, advisory director William J Burns, Detroit, continues as executive director

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45, Central daylight saving time The speaker will be Dr W W Bauer The next three broadcasts will be as follows

July 5 Death Angel
July 12 A Healthful Vacation
July 19 Entertaining the Convalescent Child

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION PUBLIC HEALTH ETC)

ARIZONA

Public Health Meeting—At the seventh annual meeting of the Arizona Public Health Association, Prescott, June 5-6, Dr William P Shepard San Francisco, among others, spoke on Present-Day Opportunities for the Practicing Medical Profession in the Field of Public Health, Dr Warren F Fox, director, Imperial County Health Unit, El Centro, Calif., 'Problems of the County Health Unit' and Mr H C Moore, chief of the Los Angeles Station, U S Food and Drug Administration, 'Menace of Spray Residue'

State Medical Election—Dr Charles R K Swetnam, Prescott, was chosen president-elect of the Arizona State Medical Association at its annual meeting in Prescott June 7-9, Dr Meade Clyne, Tucson, was installed as president, and Dr Clarence F Harbridge, Phoenix, was reelected secretary The next session will be in Phoenix Out of state speakers included Drs Dudley A Smith, San Francisco, on 'Menace of Rectal Suppositories—Care of Rectal Cases' Edward Clarence Moore, Los Angeles, 'Preoperative Preparation and Post-operative Care', Howard K Gray, Rochester, Minn., 'Surgery of the Biliary Tract', Arthur E Smith, Los Angeles, 'Plastic and Reconstructive Surgery of the Head' Samuel D Ingham, Los Angeles, 'Neurologic Conditions Commonly Associated with Diabetes, Pellagra and Pernicious Anemia' Francis C Goodwin, El Paso 'A Bone Brace to Prevent Toe Drop in Paralytics,' and George T Colvard, Deming, N M, 'Rural Obstetrics—Delivery in the Home' Other speakers included the following physicians

William O Sweek and Guy C French Phoenix Intestinal Obstruction
Zebud M Flinn Prescott Anorexia
William Roy Hewitt Tucson Proctoscopy as an Aid to Diagnosis
Ralph F Palmer Phoenix Rating Permanent Partial Disability by Functional Measurements
Max Pinner Tucson Physiology of Pulmonary Collapse
Howell S Randolph Phoenix Pneumothorax Treatment in Acute Lobar Pneumonia—Report on Eighteen Cases
William Warner Watkins Phoenix Roentgen Therapy of Inflammations
Louis C B Baldwin Phoenix Treatment of Secondary Anemia
Robert S Flinn Phoenix Treatment of Nephritis
Robert K Smith Tucson Postpartum Hemorrhage
Meyer I Leff Glendale Common Sense About Medical Ethics

CALIFORNIA

Personal—Dr Edward B Shaw has been promoted to associate clinical professor of pediatrics at the University of California Medical School, San Francisco effective July 1—Dr Wilton L Halverson has been appointed health officer of Pasadena, succeeding Dr Jay D Dunshee who is now health director of the California State Department of Public Health—Dr Charles Newell Mell is the new health officer of Emeryville succeeding Dr Emily H Emery—Dr Harold G Gentry has resigned as health officer of Redlands

Deaths from Automobile Accidents Increase—There were 2403 deaths caused by automobile accidents in California in 1933, as compared with 2347 in 1932 Of the first total, 1816 victims were men and 587 were women Fewer deaths occurred in collisions of motor vehicles with pedestrians but

more in collisions of motor vehicles with other motor vehicles, railroad trains and electric cars Out of 809 deaths in accidents involving motor vehicles and pedestrians, 221 were of persons 65 years of age and over, while fatalities in noncollision accidents involved the age group 15 to 24 years More deaths in collisions of motor vehicles with motor vehicles occurred in the age groups 15 to 24 years and 25 to 34 years than any others

COLORADO

Course in Ophthalmology and Otolaryngology—The twelfth annual meeting of the Colorado Congress of Ophthalmology with its attendant graduate course in ophthalmology and otolaryngology will be given in Denver, July 23-August 4, a week to be devoted to each subject Guest speakers will be Drs Sanford R Gifford, Chicago, Frank E Burch, St Paul, Edward Cecil Sewall, San Francisco, Isidore Friesner, New York, and Gordon B New, Rochester, Minn The fee for the course is \$50 and application for registration should be made to Dr Harry L Whitaker, 1234 Republic Building, Denver

CONNECTICUT

Compulsory Examination of Prisoners—The Public Health Council of Connecticut recently passed the following regulations as amendments to the sanitary code, effective June 15

The conviction of any person for any offense involving sexual promiscuity or illicit sex relations shall constitute reasonable grounds for a health officer to believe that that person may have been exposed to a communicable disease and shall justify the examination and such other measures of control of that individual as are deemed necessary and proper by the state department of health for the protection of public health and the prevention of spreading of diseases

It shall be the duty of the warden or other person in charge of any prison or jail in the state of Connecticut to notify the prison or jail physician in writing within twenty four hours on the receipt of a prisoner who may have been exposed to a communicable disease and of every prisoner who has been convicted of any offense involving sexual promiscuity or illicit sexual relations A routine medical examination shall be made on every prisoner whose conviction involves sexual promiscuity or illicit sex relations Upon expiration of the sentence any person having syphilis or gonorrhea whether in an infectious or noninfectious stage in need of follow up treatment shall be reported to the state health department

FLORIDA

Personal—Honorary memberships were conferred on Drs Andrew P Albaugh, Tarpon Springs, John D Peabody, St Petersburg and Charles L Jennings Jacksonville, by the Florida Medical Association at its annual meeting in Jacksonville April 30—Dr Leland F Carlton Tampa, was named president-elect of the Florida Railway Surgeons Association at its annual meeting in Jacksonville, April 30 and Dr Walter C Page, Cocoa, was installed as president Dr Edmund W Warren Palatka, for many years secretary-treasurer, was made a life member

Society News—Dr Odis G Kendrick Tallahassee was elected chairman of the Florida Crippled Children's Commission at its annual meeting recently—The Winter Haven Medical Society was recently created with Drs Omer R Alexander and Wiley T Simpson as president and secretary respectively—Dr Horton R Casparis, Nashville was the guest speaker at the annual session of the Florida Tuberculosis and Health Association in Jacksonville, April 30, his subject was "Prevention and Control of Tuberculosis"

ILLINOIS

Annual Clinic—The Winnebago County Medical Society cooperated with St Anthony's Hospital Rockford in sponsoring the fourth annual clinic at the institution in May Speakers included the following physicians

David S Hillis associate professor of obstetrics Northwestern University Medical School Chicago
Robert A Black professor of pediatrics Loyola University School of Medicine Chicago
Max S Wien assistant professor of dermatology University of Illinois School of Medicine Chicago
Henry W Meyerdinger associate professor of orthopedic surgery University of Minnesota Graduate School of Medicine Rochester Minn
Aaron Arkin associate clinical professor of medicine Rush Medical College Chicago
Theodor Lang pathologist of St Anthony's Hospital

Chicago

Dr C J Herrick Becomes Professor Emeritus—Charles Judson Herrick, ScD chairman, department of anatomy, Division of Biological Sciences University of Chicago, will become emeritus professor in July, having reached the retirement age The administration of the department during the coming year has been referred to a committee consisting of George W Bartelmez, PhD, Dr Basil C H Harvey and Dr Charles H Swift Dr Herrick succeeded Dr Robert R

Bensley, who became professor emeritus in 1933 after holding the position since 1906 Both Dr Herrick and Dr Bensley will continue their research in the Hull Laboratory of Anatomy

IOWA

Society News—Dr Edna K Sexsmith, Greenfield, was elected president of the State Society of Iowa Medical Women at its annual meeting in Des Moines, May 8 Dr Cora B W Choate, Marshalltown, is secretary—At a joint meeting of the Pottawattamie and Woodbury County medical societies in Council Bluffs, May 29, Dr George W Koch, Sioux City, among other speakers, discussed "Duodenal Stasis"—Dr Frank W Fordyce spoke on "Perforation of Peptic Ulcer" before the Des Moines Academy of Medicine and Polk County Medical Society, May 29, and Drs Nevin Boyd Anderson and Dwight C Wirtz on "Etiology of Goiter and Its Relation to Children in Des Moines" and "Some Factors of the Backache Syndrome," respectively

KENTUCKY

Personal—It is reported that Dr John D Jackson, Danville, has been named physician to the Kentucky School for the Deaf, Danville, succeeding Dr Oscar L May—Dr William R Thompson, Lexington, has been appointed psychiatrist at the Central State Hospital at Lakeland Dr Thompson was formerly assistant superintendent of the Eastern State Hospital at Lexington but recently has been engaged in private practice

Society News—Speakers before the Lawrence County Medical Society, Louisa, May 3, were Drs Walter E Vest and Robert J Wilkinson, Huntington, W Va, on "Abscess of the Lungs" and "Cancer of the Breast," respectively, and Joshua B Lukins, Louisville, "The Legal Aspect of Medicine"—Speakers at the semiannual meeting of the Fifth District Medical Society, Carrollton, May 10, were Drs Isaac A Arnold, on gas gangrene, David Y Keith, radiology in general practice, and Louis Wallace Frank, uterine carcinoma, all of Louisville.—At a meeting of the Third District Medical Society, Bowling Green, April 18, speakers were Drs Austin Bell, Hopkinsville, Harrison S Shoulders, Hollis E Johnson and Alfred Blalock, all of Nashville All discussed aspects of tuberculosis—Dr John S Boggess, Washington, D C, presented a paper on "Menace of Human Defectives" before the Jefferson County Medical Society, June 18

MASSACHUSETTS

Personal—Dr Hans Zinsser, professor of bacteriology and immunology Harvard Medical School, will go to the University of Paris for the second half of the academic year 1934-1935 as exchange professor from Harvard

University News—During the annual meeting of the Massachusetts State Medical Society, a local committee sponsored a luncheon meeting of graduates of the University of Maryland Medical School, Baltimore Medical College and the College of Physicians and Surgeons, Baltimore, now residing in Massachusetts, about fifty of the more than 200 graduates of these schools now practicing in the state attended the meeting, the first one held in twenty years It is planned to hold a similar meeting in Boston next year Dr Charles E Gill, 8 Irvington Street, Boston is secretary

Library of Legal Medicine—The George Burgess Magrath Library of Legal Medicine at Harvard Medical School was dedicated, May 23 Housed in the Faculty Club, the library is named for Dr Magrath medical examiner of Suffolk County, who is the first occupant of the chair of legal medicine at Harvard This chair was established in 1932 by Mrs Francis Gleffner Lee of Littleton, N H, who is also the donor of the new library The library will have 1 000 volumes of rare editions According to the *New England Journal of Medicine*, it is the intention of the donor that it shall be the best collection of literature extant relating to the specialty

MICHIGAN

Society News—Dr Howard H Cummings, Ann Arbor addressed the Monroe County Medical Society, April 19 on Gynecology and the General Practitioner—At a meeting of the St Clair County Medical Society in Port Huron, May 15 Dr Frederick C Kidner, Detroit discussed fractures—The Houghton County Medical Society was addressed in Houghton June 5 by Drs Harry E Johnson Redridge and Frank F Marshall, L'Anse on Mucin Treatment of Gastric Ulcer and "Asthma Etiologic Factors" respectively—Dr Warren L Babcock, medical director Grace Hospital Detroit was elected president of the Michigan Hospital Association at the annual session, May 25

MINNESOTA

Impostor Reinardy Sentenced—Robert G Reinardy, St Paul, was sentenced by Judge Michael of the district court, April 27, to a term of not to exceed ten years at the St Cloud Reformatory, following his plea of guilty to a charge of forgery in the second degree For the past six months, Reinardy has been posing in St Paul as a physician under the name of Dr R G Brian Using this name, he cashed a check for \$9 in a grocery store When the check returned from the bank marked "no account" the proprietress telephoned the state board of medical examiners for the address of Dr Brian Since there was no Dr Brian registered under the basic science law, an investigation followed and resulted in Reinardy's arrest April 16 A kit containing medicines and narcotics was found in his home Reinardy admitted that he had cashed several checks and posed as a physician He examined patients and furnished them with medicine he said, but denied that he ever made a charge for his services His sentence was stayed and he was placed on probation for three years In addition, he was ordered to make full restitution for the checks he cashed, which, it was stated, approximate \$465

MISSOURI

Dr Cowdry Gives First Charlton Lecture—Edmund V Cowdry, Ph D, professor of cytology, Washington University School of Medicine, St Louis, delivered the first annual Harry Hayward Charlton Memorial Lecture in anatomy at the University of Missouri School of Medicine, May 21 His subject was "The Significance of Nuclear Changes in Virus Diseases"

Society News—Dr Carliss Malone Stroud addressed the St Louis County Medical Society, May 23, on "Diagnosis and Treatment of Certain Allergic Conditions"—Drs Higdon B Elkins and George E Grim addressed the Adair County Medical Society in Kirksville, April 5 on nephritis—At a meeting of the Buchanan County Medical Society, May 2, Dr Frederick Gregg Thompson, St Joseph, discussed "Section of the Phrenic Nerve in the Neck"—Dr William A Fuson, Trenton, talked on "Sickle Cell Anemia" before the Grundy County Medical Society at Trenton, May 1—Dr Arthur E Hertzler, Halstead, Kan addressed the Jasper County Medical Society, April 24, on diagnostic problems of acute conditions in the abdomen

NEW HAMPSHIRE

Discharge of Waste into Lake Prohibited—The discharge of sewage at any point on the waters of Lake Winnepesaukee is prohibited under a recent regulation of the state board of health There is a similar prohibition already in effect at Lake Pausus This regulation applies to vessels, boats and other structures operating or maintained on the waters of these lakes

NEW YORK

Dr Hartman Goes to Ohio State University—Frank A Hartman, Ph D, professor of physiology at the University of Buffalo since 1919, has accepted the professorship of physiology at the Ohio State University School of Medicine Columbus, according to the *New York Times* June 24 Dr Hartman was awarded the Chancellor's Medal of the University of Buffalo in 1932, in recognition of his research on Addison's disease

Personal—The course in surgical methods in experimental biology to be held this summer at the Biological Laboratory, Cold Spring Harbor, will be directed by Dr George W Corner, professor of anatomy University of Rochester School of Medicine and Dentistry, Rochester instead of Edgar Allen, Ph D, professor of anatomy, Yale University School of Medicine Dr Allen has had to change his plans on account of illness—Dr Charles M Burdick has retired as superintendent of the Dannemora State Hospital for Criminal Insane, a position held since 1922

New York City

Society News—The Medical Society of the County of New York was addressed May 28 by Dr Abraham J Rongy on "The History of Abortion" Dr Isador W Kahn "The Abortion Racket in New York City" and Reed B Dawson Esq "The Legal Responsibilities of the Physician in Cases of Abortion"

Personal—Dr Sam Z Levine has been appointed acting pediatrician in chief to New York Hospital and acting professor of pediatrics at Cornell University Medical College, succeeding Dr Oscar M Schloss who recently became professor of clinical pediatrics and attending pediatrician to the

hospital—Dr Charles Gordon Heyd was recently appointed professor of clinical surgery and executive officer of the department of surgery of the New York Post-Graduate Medical School and not at Columbia University College of Physicians and Surgeons, as reported in THE JOURNAL, June 9, page 1949. Dr Allen O Whipple is executive officer of the department of surgery at the College of Physicians and Surgeons, professor of surgery and director of the department of surgery at Presbyterian Hospital.—The honorary degree of doctor of science was bestowed on Drs Florence R Sabin and Ludwig W Kast by Syracuse University at the annual commencement, June 4. At the same time Dr Livingston Farrand, president of Cornell University, received the honorary degree of doctor of laws.—Dr William Seaman Bambridge, after twenty-one years service, has been promoted to medical director with the rank of captain in the U S Naval Reserve.

NORTH DAKOTA

State Medical Election—Dr Archibald D McCannel Minot, was chosen president-elect of the North Dakota State Medical Association at the annual meeting, May 29. Dr Clyde E Stackhouse, Bismarck, was installed as president and Dr Albert W Skelsey, Fargo, was reelected secretary. The next annual session will be in Minot.

PENNSYLVANIA

Society News—Drs John T Burnite and Josiah F Reed addressed the Dauphin County Medical Society, Harrisburg, June 5, on "Modern Treatment of Sterility" and "Modern Contraceptive Methods".—Dr Pascal Brooke Bland, Philadelphia, addressed the Harrisburg Academy of Medicine, June 19 on "Intracranial Damage of the New-Born".

Medical Alumni Day—The University of Pittsburgh School of Medicine held its first homecoming day for alumni June 2. More than fifty faculty members conducted clinics and at luncheon Dr Ralph H Boots, New York, of the class of 1915, made an address on "Medical Viewpoints Regarding Arthritic Diseases". The alumni also joined in the annual faculty dinner to the graduating class, at which Dean Raleigh R Huggins presided and Dr deWayne G Richey, Pittsburgh, spoke on "Medical Traditions of Western Pennsylvania".

Philadelphia

Lowest Record for Typhoid—Philadelphia had 105 cases of typhoid with twelve deaths during the past year, the lowest mark ever reached, the health department announced. In 1910 there were 1,745 cases with 272 deaths, in 1925 there were 234 cases with 45 deaths.

Hospital News—Dr Mitchell Bernstein was recently elected chief of medical service at the Jewish Hospital.—Approximately 900 tuberculosis patients were cared for in general hospitals of Philadelphia during 1933, according to a survey made by the Philadelphia Health Council and Tuberculosis Committee, this marks a radical change from the former policy of general hospitals, which would not accept cases of tuberculosis until recently.

Personal—Dr Robert H Ivy, professor of maxillofacial surgery, University of Pennsylvania Graduate School of Medicine, has been elected to membership in the Imperial German Academy of Natural Sciences.—Dr Luther C Peter received the honorary degree of doctor of science from Susquehanna University at the annual commencement June 4.—The honorary degree of master of arts in medicine was conferred on Dr Wilmer Krusen at the annual commencement of Hahnemann Medical College and Hospital, June 7, Dr Krusen delivered the address of the occasion.

Faculty Changes at Jefferson—Dr Ross V Patterson, dean of Jefferson Medical College since 1906, has been named Sutherland M Prevost professor of therapeutics, succeeding Dr E Quin Thornton, who became emeritus professor of therapeutics. Other changes in the faculty include the following promotions:

Dr Michael A Burns professor of neurology
Dr John M Fisher clinical professor of surgery
Dr John T Brundage assistant professor of pharmacology
Dr Robert M Lukens assistant professor of bronchoscopy and esophagoscopy

At the annual alumni dinner May 31, busts of Mr Alba B Johnson, president of the board of trustees and of Dr Patterson the dean were presented to the college. The graduating class of 1934 presented a portrait of Dr J Torrance Rugh James Edwards professor of orthopedic surgery to the college April 27.

RHODE ISLAND

State Medical Meeting and Election—Dr Roland Hammond, Providence, was chosen president-elect of the Rhode Island Medical Society at the annual meeting, June 7, in Providence. Dr Albert H Miller, Providence, was installed as president and Dr James W Leech, Providence, was reelected secretary. The annual session for 1935 will be held in Providence, June 6. Speakers at this year's session were:

Dr Frank M Adams Providence Middle Ear Disease
Dr Frank S Hale Providence Pernicious Vomiting of Pregnancy
Dr Clifton B Leech Providence Use of Quinidine Sulphate in Heart Disease
Dr Eske H Windsberg, Providence Total Removal of Right Lung for Bronchiectasis

A symposium on diseases of the biliary system was presented by Drs Irving J Walker, Franklin W White, William Richard Ohler and John B Hazard, Boston. Senator Felix Hebert was the speaker at the annual dinner at the Metacomet Golf Club in the evening.

SOUTH DAKOTA

Personal—Dr Gustav A Landmann, for twenty years mayor of Scotland was recently reelected.—Dr John S Tschetter has been named city commissioner of Huron, in charge of the public safety department.

TEXAS

Health at El Paso—Telegraphic reports to the U S Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended June 16, indicate that the highest mortality rate (21) appears for El Paso, and the rate for the group of cities as a whole, 10.3. The mortality rate for El Paso for the corresponding period last year was 11 and for the group of cities, 10.6. The annual rate for eighty-six cities for the twenty-four weeks of 1934 was 12.2 as against a rate of 11.6 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

GENERAL

Results of Board Examinations—Sixty-one candidates were examined by the American Board of Obstetrics and Gynecology in Cleveland, June 11-12. Fifty were approved, ten were conditioned and one failed.

Eradication of Animal Diseases—Plans for eradication of animal diseases were to have been launched the first part of June in twenty-four states and the District of Columbia. The activities will be a continuation, along intensified lines, of disease eradication programs conducted in the past by the bureau of animal industry and cooperating state and local veterinary officials. The states in which the work will be expanded first, largely in cattle tuberculosis eradication, are Arizona, Arkansas, California, Colorado, Georgia, Indiana, Iowa, Kansas, Minnesota, Mississippi, Missouri, Montana, Nebraska, New Mexico, New York, Ohio, Oklahoma, Pennsylvania, Tennessee, Texas, Vermont, Virginia, Wisconsin, Wyoming and the District of Columbia.

Society News—The American College of Physicians will hold its nineteenth annual clinical session in Philadelphia, April 29-May 3, 1935.—Mr Charles Frankenger, librarian, Medical Society of the County of Kings and Academy of Medicine of Brooklyn, was elected president of the Medical Library Association at its thirty-sixth annual meeting in Baltimore, May 21-24, and Miss Frances N A Whitman, librarian, Harvard University, schools of medicine and public health, Boston, secretary. The next annual session will be held in Rochester N Y in June 1935.—The Central Association of Obstetricians and Gynecologists will hold its fifth annual meeting in Milwaukee October 5-7.

Sight Conservation Activities—The National Society for the Prevention of Blindness recorded in its annual report among other points that five states are now requiring automobiles to be equipped with nonshatterable glass as a means of safety, that this type of glass has been perfected for use in spectacles that the society has adopted a positive program in cooperation with other organizations of active promotion of education in prenatal care for syphilitic mothers, that in spite of curtailment of many activities in education, seventeen new sight saving classes were established during the year. A trial study of the causes of blindness among children in schools for the blind disclosed that many of these children might regain

sight through proper medical or surgical treatment, and the society in cooperation with the American Foundation for the Blind and the Committee on Statistics of the Blind is taking measures to provide treatment

Physicians Requested to Safeguard Their Narcotics—The Bureau of Narcotics of the U S Treasury has requested in connection with its annual report of thefts of drugs that physicians and druggists exercise greater precautions looking to a further reduction of these thefts. The number of thefts in 1933 was 831, considerably less than the number in 1932, but still large, especially when it is considered that all the drugs went into illicit channels, Acting Commissioner Louis Ruppel pointed out. All legitimate handlers of narcotic drugs are asked to store them under lock and key, preferably in metal cabinets or safes, since the check up of many thefts has shown that they were committed without trouble, owing to the use of wooden cabinets and unlocked cases. Legal purveyors were cautioned also against letting the government order forms issued to the drug trade and the medical profession fall into the hands of illicit traffickers and addicts. The greatest number of thefts were reported in the South and Southwest.

PUERTO RICO

Malaria Control—The New York *Times* reports that a program of malaria control in Puerto Rico has resulted in an appreciable reduction in the death rate. In the first two months 51,000 patients were treated with quinine, which was purchased in sufficient quantity for 28,000,000 doses. Public school records showed that absences of children had been cut from 40 to 10 per cent.

CANADA

University News—Dr Charles H Best, professor of physiology and assistant professor of hygiene and preventive medicine, University of Toronto Faculty of Medicine gave a course of three lectures at University College London, recently on "Role of the Liver in the Metabolism of Carbohydrate and Fat."

Personal—Dr George J Wherrett of the staff of the Fort Qu'Appelle Sanatorium, Fort San, has been appointed executive secretary of the Canadian Tuberculosis Association. He succeeds Dr Robert E Wodehouse, who was recently appointed deputy minister of health in the department of pensions and national health at Ottawa.

Celebration in Winnipeg—In connection with a celebration of the fiftieth anniversary of the University of Manitoba, a "clinical week" was held by the medical school, May 14-19. Subjects handled in clinics included fractures, surgical emergencies, functional disorders of the nervous system, obstetric subjects, diseases of children and a medical symposium on digitalis therapy, anemias, essential hypertension and diarrhea in adults. Addresses were made at luncheon and in the evening by the following speakers, among others:

Dr David A Stewart, Ninette Progress of Medicine in Fifty Years
Dr Norman M Keith, Rochester Minn, Essential Hypertension
Dr William Boyd, Winnipeg, The Gordon Bell Memorial Lecture

FOREIGN

Dr Martin Heads Pasteur Institute—Dr Louis Martin, nominal head of the Pasteur Institute since the deaths of Dr Albert Calmette and Dr Emile Roux last winter and chief of the serotherapy service, was officially appointed director by the institute board, May 16, the New York *Times* reported. He has been associated with the institute for forty years. Dr M G Ramon, chief of the veterinary service of the Pasteur Institute at Garches, succeeds Dr Calmette as under director.

International Congress of Radiology—The fourth International Congress of Radiology will be held at Zurich, Switzerland, July 24-31. Meetings will be held during the first four days at the University of Zurich and the Federal Institute of Technology. The Swiss Roentgen Society will entertain the delegates at a luncheon on the opening day, a festival of Swiss national costumes will be presented, July 27, and there will be a trip to St Moritz, July 28. Dr Hans E Walther, Zurich, Gloriastrasse 14 is secretary of the congress.

British Prizes Awarded—The Sir Charles Hastings Clinical Prize of the British Medical Association for 1934 has been awarded to Dr Dulcie Helen Lukis, New Malden for a study entitled "The Problems of Anesthesia in General Practice." The Katherine Bishop Harman Prize, awarded every second year for study and research in connection with risks apt to arise in pregnancy and childbirth was presented

to Prof John M Munro Kerr, Glasgow, for his clinical study "Maternal Mortality and Morbidity: A Study of Their Problems."

International League Against Cancer—An International League for the Combat of Cancer was founded in Paris, March 24, 1934, at a meeting attended by representatives of thirty-two nations, it is reported. Former French minister Godart was elected president. It is planned to have a permanent office in Paris and to publish a yearly report. The league also plans to organize an international convention in Rome, probably for 1936, to seek international cooperation in the field of statistics and in the campaign against quackery and in exchange of literature.

International Conference on Tuberculosis—The ninth conference of the International Union Against Tuberculosis will be held in Warsaw, Poland, September 4-6. Three subjects will be discussed: biologic variations of the tubercle bacillus introduced by Professor Karwacki, Poland; tuberculosis of the bones and joints, by Professor Putti, Italy; and use and organization of tuberculosis dispensaries, by Prof Leon Bernard, France. Americans listed for discussions are Drs Esmond R Long, Philadelphia, Clarence L Hyde, East Akron Ohio, James A Miller, New York, and Berthold S Pollak, Secaucus, N J. Information may be obtained from the National Tuberculosis Association, 50 West Fiftieth Street, New York. A special party is being arranged to go from the United States, and for those who can leave in advance a trip to Russia is scheduled that will permit delegates to arrive in Warsaw in time for the meeting.

Personal—Sir Robert McCarrison of the Indian Medical Service recently was awarded the prize of the Arnold Flinker and Julius Wagner-Jauregg Foundation of Vienna for a paper on the etiology of goiter which he delivered at the International Congress on Goiter in Bern in 1933. The prize, 2,000 Austrian shillings, had never before been awarded outside of Austria. Dr Edward Johnson Wayne has been appointed professor of pharmacology at the University of Sheffield. He will succeed Dr Edward Mellanby, who was appointed in 1933, but was almost immediately afterward appointed secretary of the Medical Research Council following the death of Sir Walter Fletcher. Dr Hugh Crichton-Miller has resigned the directorship of the Institute for Medical Psychology, London. He was succeeded by Dr J R Rees. Dr Miller founded the institute. Dr Karl Frederick Wenckebach, emeritus professor of medical pathology and therapy at the University of Vienna, recently celebrated his seventieth birthday. Dr Andrew Hunter, professor of physiologic chemistry, University of Glasgow, has been elected dean of the faculty of medicine for 1934. Dr Farquhar Macrae, formerly lecturer in clinical surgery, University of Glasgow, has been appointed secretary of the Indian Medical Council, organized in 1933. Lord Moynihan, emeritus professor of surgery, University of Leeds, and Sir Frederick Gowland Hopkins, president of the Royal Society and professor of biochemistry, University of Cambridge, received the honorary degree of doctor of laws from the University of St Andrews at its graduation exercises, June 29. Mr Frank W Ramsay, Bournemouth, president-elect of the British Medical Association, has resigned because of ill health and Dr Sydney Watson Smith has been appointed to fill the office until the annual meeting of the association. A motion was also adopted to nominate Dr Smith for president for 1934-1935.

Government Services

Memorial to Colonel Bruns Dedicated

The dedication of a portrait of Col Earl H Bruns took place in the Officers' Club of the Fitzsimons General Hospital, Denver, May 24. Col Carroll D Buck was chairman. Speakers on the program included Dr Harry J Corper, "Evolution of the Memorial." Governor Ed C Johnson, "Colorado's Appreciation," Mayor George D Begole, Denver and Colonel Bruns", Major William C Pollock, "Colonel Bruns the Teacher", Major Paul M Crawford, "Colonel Bruns the Physician", Col Robert M Hardaway, "Colonel Bruns and His Civilian Conferees." Dr Arnold Minnig, Tributes, Dr Cicero L Lincoln Jr, "Colonel Bruns' Contributions to Medical Literature." Dr Henry Sewall presented the portrait to the tuberculosis service of the U S Army. The artist was Mr J I McClymont. Colonel Bruns died in 1933.

LONDON

(From Our Regular Correspondent)

June 2, 1934

The Development of Municipal Hospitals

The president of the Socialist Medical Association is Mr Somerville Hastings, a laryngologist to the Middlesex Hospital, the ablest and most important of the small band of medical socialists. The London County Council has been captured by the socialists (not because London has become socialist but because of the apathy of a large part of the electorate), and Mr Hastings is now chairman of the public health committee, which controls the biggest public health organization in the world and the huge municipal hospital system of 30,000 beds. Mr Hastings' scheme for completely socializing the medical profession has been described in *THE JOURNAL* (February 24, p 628). In opening a discussion at the annual meeting of the Socialist Medical Association (*Lancet* May 26 p 1136) on the "Present Scope and Future Development of Municipal Hospitals" he pointed out that recent legislation transferred the powers of "guardians of the poor," who maintained hospitals that were mainly infirmaries for the poor to the local health authorities. The latter were empowered to establish hospitals, in the ordinary sense of the term, for the use of the inhabitants of their districts. The result was that a large number of authorities (including London) had appropriated the old poor-law hospitals and were running them as municipal hospitals. But Mr Hastings thought it a disaster—naturally as a socialist he would—that the cost of maintenance and treatment for any disease, other than infectious, had to be recovered from the patient who could afford to pay. This severance from the poor law opened enormous possibilities of development especially in urban areas. Specialization became possible, certain wards in one hospital could be set aside for the treatment of cancer by radium and roentgen rays, in another hospital for eye cases, facilities could be provided for thoracic surgery or bronchoscopic work in a third, and so on.

A local authority could not legally refuse admission to any destitute patient if his medical necessities demanded immediate hospital treatment. (This represents the old poor law treatment.) Accordingly, the number of beds had to be the highest that could possibly be demanded. Consequently in the summer months a good many beds were vacant, which could be used for operations that were not urgent. A consultative outpatient department then became essential. There the local authority could carry out its tuberculosis, venereal disease and school clinics. Thus medical centers for the districts could be developed. This unification should prove of value for research and medical education. Instruction in fevers had long been given in municipal hospitals, and everything possible should be done to bring the stimulating and critical influence of students within the walls of all hospitals. There was nothing to prevent the development of medical schools in association with municipal hospitals. Mr Hastings might have given the example of the Hammersmith Hospital, which, as described in previous letters to *THE JOURNAL* is to be the hospital of the recently formed Postgraduate Medical School of London. This is a municipal hospital. It was not found possible to associate the school with any of the great voluntary hospitals, as they are medical schools fully occupied in undergraduate teaching. Mr Hastings stated that these developments were increasing confidence in municipal hospitals, which were being preferred by many to voluntary hospitals. The public was beginning to feel that the hospitals belonged to them and that they could go there

by right of citizenship and not as charity patients, and should anything go amiss they had the right to protest through their elected representatives.

Moving Roentgen Ray Pictures

At the Royal Society of Medicine, Dr Russell Reynolds gave a remarkable demonstration of moving pictures taken of subjects exposed to roentgen rays. As long ago as 1896, within a few months of Roentgen's discovery, Dr John MacIntyre demonstrated in Glasgow a film of the movement of the bones of a frog's leg taken with roentgen rays. But this was very large, and for human subjects the direct method, whereby a continuous film is substituted for the usual "still" picture, presents great difficulties. The method adopted by Dr Reynolds is to allow the rays to produce their effect on a fluorescent screen in the ordinary way and then photograph this with a film camera. He has so simplified the apparatus that he was able to take a picture of a moving hand at the meeting and produce this fully developed at its close. By moving pictures the exact movements at a joint, whether healthy or diseased can be studied and demonstrated to students. The movements of the heart and lungs are also shown in a form easy to study, and so are the movements of the alimentary canal after a bismuth meal. The possibility of linking up sound with the pictures has been considered. The movement and sounds of the heart might be recorded together and in this way some of the teaching with regard to what is heard with the stethoscope might be discontinued. At the same meeting Dr R Janker of Bonn gave a demonstration of moving roentgen ray films similarly produced.

The Reduction of Disease Among Milk Cattle

A committee appointed by the government to consider measures for reduction of disease among milk cattle, particularly of tuberculosis has presented a report. The president was Sir F G Hopkins, the biochemist, and the members included such experts as Prof E P Cathcart (physiologist), Dr A Stanley Griffith (pathologist and authority on bovine tuberculosis), and Prof J H Jones.

DISEASE COMMUNICATED TO MAN

Bovine tuberculosis is responsible for more than 2,500 deaths annually in Great Britain, and for a still greater amount of serious illness. Undulant fever is rarely reported in Great Britain, but possibly it often passes unrecognized. About 100 outbreaks of epidemic disease, due either to mastitis in cattle or to subsequent infection of milk by those handling it, have been recorded in this country since 1903. The most important outbreak occurred at Hove in 1929, when 1,000 families were affected and sixty-three deaths occurred. The committee recommended that routine veterinary inspection should be made obligatory for all local authorities. The veterinary service should be expanded under the immediate control of local authorities but with coordinating powers of the department of agriculture. The veterinary officers should be responsible for eradication of disease and should do the tuberculin testing for the purpose of milk designation.

THE ERADICATION OF TUBERCULOSIS

This scheme, which will require the active supervision of the Ministry of Agriculture, should provide for the following: 1 A list of tuberculosis-free herds tested with tuberculin from time to time under official supervision. 2 Free advice and free tuberculin-testing for owners who agree to make bona fide efforts to free their herds from tuberculosis, or who have established free herds. 3 Financial help where necessary by way of loans to approved owners for expenditure required by the veterinary inspector as necessary to eradication. 4 Securing to owners of disease-free herds of a higher price for their

milk 5 Measures to secure tuberculosis-free cattle being moved about and exposed for sale without the risk of contact with other cattle 6 All milk should be sold under an official designation and should attain a fixed standard of cleanliness It should conform to one of the following designations (a) "Certified milk"—which has not undergone any heat treatment and is derived from tubercle-free herds This milk should not be required to be bottled at the farm (b) "Pasteurized milk"—which has undergone once only a process of approved heat treatment in a plant licensed for the purpose (c) "Sterilized milk"—which has been raised to the boiling point or higher in a licensed plant (d) "Uncertified milk"—which has undergone no heat treatment and is not derived from tubercle-free herds but attains a certain hygienic standard

Increase in the Number of Physicians

The Medical Register at the beginning of the present year contained 56 741 names, the largest ever reached, and 340 students more than last year had registered their names At the session of the General Medical Council of Medical Education and Registration Sir Norman Walker in his presidential address quoted these figures and reminded the council that its first object was to improve medical education The boundaries of medicine were ever extending, and the last twenty years had seen even greater and more rapid changes than those that had led to the passing of the Medical Act of 1886 The council could not, however, frame a model curriculum which would suit every country and every school, and a hard-and-fast arrangement of subjects was impossible even if desirable Each licensing body was free to try out new methods and those found successful were likely to be imitated and perhaps improved on by others Other countries did not realize how much we gained from our unique system of external examiners (examiners drawn from outside medical schools) The meeting at the council of teachers from different schools was perhaps the most efficient way of diffusing information

The Effect of Noise on Work

The efforts to deal with the noise evil, produced by machinery in modern civilization, especially by automobile traffic, have been described previously (*THE JOURNAL*, Oct 21, 1933, p 1325, Oct 28, 1933, p 1402) The Anti-Noise League was formed with the support of prominent physicians, for the purpose of inducing the authorities to regulate by law forms of noise that are manifestly injurious to the community Lord Horder, chairman of the Anti-Noise League, presided at a lecture on "Research into the Effects of Noise on Work," delivered at the National Institute of Industrial Psychology by Prof F C Bartlett, director of the Psychological Laboratory of the University of Cambridge Professor Bartlett said that the world became more and more full of noise each year In almost every civilized country committees were appointed to investigate what was called "the menace of noise," and the facts about noise were slowly accumulating Noise might be defined as any sound which was treated as a nuisance and the qualities of any particular sound depended largely on the background against which it was experienced But certain characteristics of sound made them attract attention on almost any background The most important were loudness, ambiguity of direction and unfamiliarity It was only in certain special occupations that there was any evidence of serious damage to hearing by noise The boilermaker working inside a boiler might have to endure a loudness considerably greater than anything used in experiments on human beings Moreover, many of the constituents of the noise were of high frequency so that their loudness was greatly amplified That continued exposure might produce middle-ear inflammation and lead to permanent deafness seemed certain Some other industries might produce more or less similar effects, but except for

highly specific tasks no convincing case could be made out for loss of hearing But there were other ill effects of loud sounds The pneumatic drill, the hoot of the automobile, or the rattle of a busy city street might deafen nobody, but they masked sounds more important to the individual, such as conversation, and so produced irritation Masking was a physical effect, but its reaction on work was psychologic It slowly piled up annoyance and a feeling of defeat and so became a real enemy

PARIS

May 9, 1934

The Medical Congress of Tunis

A congress devoted to the study of medical questions pertaining to the French protectorates of northern Africa was held at Tunis under the chairmanship of Prof Charles Nicolle, now professor at the College de France in Paris but for many years director of the Institut Pasteur in Tunis Many French physicians crossed the Mediterranean for the occasion—also several Italian physicians The meeting, which was organized by the North African medical group, was presided over by Dr Brun, director of the Hopital Sadiki at Tunis The crusade against syphilis was the subject of papers by Colombani and Lepinay of Morocco, A Laeroux and Colonieu of Algeria, and Mazeris, Raynal and Louis Chauvin of Tunisia Everywhere may be observed the effects of the crusade undertaken against *Spirochaeta pallida* by the French physicians In Morocco, the mutilating tertiary types are becoming more uncommon In Algeria the number of antivenereal centers is increasing constantly (7 in 1928, 156 in 1930, and 178 in 1933) Here prostitution is the most dangerous factor In the rural districts, fatalism among the Mussulmans is a serious obstacle to the publicity campaign in favor of energetic treatment Tunisia seems to be the country the best organized to combat venereal disease The antivenereal equipment of Tunisia includes, at present, numerous detection and treatment centers for syphilis, not only at Tunis, where there is an excellent dispensary, but also in all the cities of the interior The number of doses of spirillicidal drugs, supplied gratuitously by the hygiene services, has risen from 11,551 in 1923 to 149,486 in 1932 At the same time, the expenditures have risen from 50 000 francs (\$3,250) in 1923 to 534 300 francs (\$34 729) in 1932

Eye conditions associated with congenital syphilis, so frequent in northern Africa, have been the subject of a research by Cuenot and Nataf, based on observations extending over nearly forty years and on 300,000 observations of patients, half of which were natives The authors employ mercury salts in preference to arsphenamines, which latter are used only when there are no changes in the deep membranes of the eye nor in the optic nerve They reject pentavalent arsenicals entirely

Arsenotherapy in the treatment of dementia paralytica and tabes was the second topic on the program and was presented by Dr Cassar, director of the Tunis prophylaxis center The Mussulman of Tunisia seems to have developed an immunity of his central nervous system toward attacks of *Spirochaeta pallida* Tabes and dementia paralytica are rare The treatment with arsphenamines, applied since 1919, has not changed the nature of syphilis as it appears in the natives The baneful effects of inadequate treatment with arsphenamines, which are observed in the European in the form of manifestations of the unapparent neurosyphilis, detectable by examination of the cerebrospinal fluid, are not found in the natives of Tunisia

In addition to numerous special communications presented by physicians of France and Africa, several lectures were given Professor Porot of Algiers spoke on the new ideas concerning the disorders of the cerebral circulation Dr Sabouraud of Paris on physicians as they disport themselves in fields outside of medicine Professor Morav of Paris on dermo-epidermic

grafts, Professor Debre of Paris, on tuberculosis in the child, Dr Diacono of Tunis, on the serologic problem of hemolysis, Dr Deschamps, on arteritis obliterans. In closing, Oran (Algeria) was chosen as the place of meeting for next year, and Professor Abadie was elected chairman.

The Congress of Lyons

A meeting of physicians of French hot springs and climatic resorts was held in Lyons. The attendance was large, as it was in association with Easter holidays. The study of heat treatment as applied to rheumatism, as defined for the first time at Lyons by Poncet, was the chief purpose of the meeting. Heat treatment as applied to respiratory disorders was a second topic. A somewhat new subject was touched on in several papers, namely, the pathogenic role of the humidity of the atmosphere, a subject especially fitting for Lyons, which, being situated at the confluence of the Rhone and the Saone, has a higher humidity than almost any other city of France. The days without a trace of rain are rare in Lyons. Mr Boudry of La Bourboule considered the question from the physiologic point of view. Mr Causy gave his views on the mechanism of the cause of pain by damp weather. The second day was devoted to a discussion on renal tuberculosis.

Experimentation on Man

In reviews of a rather more literary than medical tone, Professor Nicolle is publishing a series of articles on medical philosophy, characterized by perspicacity and containing conclusions of a life devoted entirely to experimentation. His articles are creating a sensation, as did also his book on the destiny of infectious diseases, in which he predicted the disappearance of certain diseases and the possible appearance of new ones. In this new series of articles he is considering the right to experiment on man. He energetically denies such a right, even on criminals. Human life should be sacred to man. One has not even the right to jeopardize one's own life. If Pasteur had inoculated himself first with rabies and the experiment had failed, it would have been a disaster for humanity. This having been said, and just at the moment when he would seem to have succeeded in convincing the reader of the truth of his statement, he admits that experimentation on man has been practiced since time immemorial and that every trial of a new medicine, a new serum, a new anesthetic, a new operative method is, essentially, experimentation, with merely the attenuation that it has always been preceded by trials on animals. But there are many instances in which conclusions based on trials on one species are not a priori applicable to other species, notably the human species. There is still a ravine to be crossed, and Nicolle reaches the conclusion that only the scientist is entitled to cross it, in the calmness of his conscience, after having weighed all the responsibilities and eventualities and having decided that the problem to be elucidated is of cardinal importance for humanity and can be solved in no other way. From this conception, to all appearances contradictory, the conclusion appears to be reached that the scientist, having no selfish interests and placed at the front of human progress, has rights belonging only to himself, which it behooves mankind to recognize. This conclusion appears somewhat strange, and Mr Nicolle states that he would not have adopted it if it had not been the only one possible, if the question was to have any issue.

The Academy's Oldest Member

Dr Guenot, formerly obstetrician to the hopital de Paris and past president of the Academy of Medicine, has completed his 102d year. His health is excellent, and he continues to carry on his studies in his library. He has presented to the Academy the two volumes that he recently published "Observations on Birds, Insects and Plants" and the third edition of the work "How to Live to Be One Hundred Years Old."

Genes, Chromosomes and Tumors

Prof K H Bauer of Breslau discussed recently the subject of hereditary biology in relation to tumors. He emphasized that at the beginning of every tumor blastoma cells develop. They originate from body cells, but modification of the cells cannot lead to tumor cells. Crossing has not been demonstrated, but a mutation of the gene can be assumed with a high degree of certainty, just as such mutation can be held responsible for the origination of hereditary diseases (multiple exostoses, xeroderma pigmentosum). The assumption that mutated genes are the substantial carriers of tumor qualities can be shown by the fact that the tumor cells give evidence not only of new but also of old functions in some form or other. A retrogression of mutation cells never occurs. Metastases and recurrences show the contamination or the remnants that support the mutation. Not every mutated body cell becomes a tumor cell, but every tumor cell is a mutated body cell. The peak of cellular division and the places of increased usage are chiefly involved. All influences that disturb the processes of regeneration further tumor formation. Examinations of tumor cells show abnormal conditions with respect to the chromosomes. In some cells, from 95 to 100 chromosomes (basic number 48) were demonstrated. In malignant tumors multiple mitoses were observed. The modifications in the number of the chromosomes furnish the stimulus for the new formation and for growth. Experimentally the agents that are employed biologically for the production of mutation in germ cells may be applied to tumor cells. Roentgen irradiation may cause roentgen carcinoma or sarcoma, likewise, radium may produce carcinoma and sarcoma in plants and animals, and arsenic may produce them in plants. As an indication of the influence of ultraviolet light, it may be stated that skin cancer in man develops only in surfaces exposed to the light. An increased incidence was observed on the skin of mariners and inhabitants of the rural regions. Tumors are a problem of the genes and the chromosomes. The therapeutic effects of roentgen rays are based on their influence on the make up of the genes. The frequency of tumors in man depends on the negative selection. The present longer duration of life leads to marked aging of the tissues and thus to carcinoma in aging persons.

Modern Work Methods

The Kaiser Wilhelm-Institut für Arbeitsphysiologie held recently a working session in Dortmund. Prof Dr Gium general director of the Kaiser Wilhelm-Gesellschaft, Berlin, explained that if Germany is to hold its own against other countries, increased importance must be laid on the highest quality of work. "We are seeking the best working methods. We are gathering experience that we may apply it in a truly social sense. Improvements in machines and apparatus are devised and tested, and our name has become known throughout the world."

A phase of the work is research on the best methods of saving the working strength of creative man, in order to preserve for him his defense forces for life in this machine age. Just what methods should be employed to accomplish this, it is the purpose of this session to discover.

Prof Dr Atzler director of the institute, introduced to the audience some of the problems of the physiology of work, the objective of which is to shape the industrial work of man in accordance with his capacities. Through years of energetic though quiet research, the weapons have been forged with the aid of which the burdens of mankind can be lightened. The maximum burden of work for juveniles, how to preserve the workman's working capacity as he grows older, and the best

methods to employ to strengthen the human body, such as have proved useful of late in the emergency field work service, have been ascertained through scientific research. Germany entails a loss of time and money from pneumoconiosis in miners, amounting to 4,500,000 marks (\$1,710,000) each year. It has been learned that susceptibility to this disease depends to a great extent on the individual structure of the nose, so that, with the aid of an ingenious apparatus, the susceptibility of applicants for work in the mines can be determined.

Prof Dr Kraut made some observations on the nutrition of workmen. Since the beginning of the economic crisis the food question among workmen has been serious. The decline in the quality of the diet is so marked that, along with other damages, there has been a reduction of working capacity. An improvement is expected primarily as a result of the measures adopted by the government and the large industrialists for the betterment of the employment situation. Greater knowledge and care in choosing the proper foods are needed. In recent studies on the food problem among workmen, a lack of high-grade animal protein was evidenced which condition can be improved with the means already at hand. The chief recommendation is an increase of milk consumption.

Attention was called also to the endeavor, by systematic research, to improve the quality of hand work so that it will be better able to compete with machine work. The form of tools used today is, to a great extent, determined by tradition rather than practical usefulness.

Heart Patients and Sport Activities

The question is often raised as to whether heart patients must renounce all participation in sports. Professor Unverricht, the director of the third Medizinische Universitätsklinik in Berlin, gives his views in the *Münchener medizinische Wochenschrift*. He takes the attitude that each individual patient must be considered separately. The desires of the patient must be considered, lest, by general prohibitions, a feeling of complete physical inferiority be induced. By careful measurement of the permissible physical activities the compensation processes demanded by the circulation of the patient with heart defects can be provided for. Thus the general capacity can be strengthened and the joy of living in such persons can be restored. Unverricht reached this conclusion on the basis of observations on juvenile patients who had been affected with mitral insufficiency, mild mitral stenoses, aortic insufficiency or mild aortic stenoses, although they presented no severe subjective symptoms. Exercising the greatest caution, he permitted the patients at first to perform passive movements and then to participate in active gymnastic exercises, finally he allowed them to engage in running, swimming, skating and paddling. He always introduced a mild form of exercise to reduce the tension and to relieve the strain, and he took care to provide also for adequate periods of rest. Before beginning a new form of exercise, the patients were required to participate in deep breathing. Every muscular movement furthers the blood circulation and lessens peripheral disturbances. It is true that the burden of the heart will be increased by the augmentation of the stroke volume. Exercise exerts a favorable influence also on the blood vessels, for they become thereby adapted to the performance of increased labor. Possibly the muscularis of the vessel walls will be strengthened and the venomotor performance will thereby be increased. Thus a compensation process has been consciously introduced, for exercise of the heart and the blood vessels is especially important for patients with heart defects to establish a reserve force in the event of a sudden increased demand on the circulatory system, whether in the form of a suddenly necessary physical exertion or to resist an attack of fever (infectious diseases).

In the changes in the size of the heart brought about under the influence of physical exercise the play of the capillaries is important, that is the development of the adaptability of the capillaries in the muscles and in the skin, hence, the evident value of air baths combined with physical exercise. Through stimulation of the skin, air baths have a tonic effect and increase the well being of the patient. Exercises requiring the exertion of one's strength to the limit, such as running or swimming a certain distance within a prescribed space of time were permitted only after completion of an adequate period of training. When the performance was increased slowly, there was never any essential enlargement of the heart. Great care was taken not to allow the patients to overexert themselves. They were supervised most carefully. No further accentuation of the exercises was permitted when any disturbances resulted, such as disturbed sleep, loss of appetite, mental depression, fatigue, irritability, or the like, symptoms that can be regarded as signs of beginning circulatory weakness and that are seen as fatigue manifestations, even in healthy sport adherents, after an exaggerated course of training. In the cases mentioned, a lowering of the blood pressure value, such as occurs in healthy persons who overexert themselves, was frequently observed. The physician must be personally familiar with the various forms of bodily exercise. The critical task of the physician is to apply to other constitutions his personal experiences, which are of course influenced by his own capacity to perform and his own bodily constitution, and to estimate the capacity of the patient's organism to react to various sport activities. If patients take a stubborn attitude and show an inclination to make records for themselves at any cost, the experiment, as far as they are concerned, should immediately be discontinued. In dealing with heart patients it must constantly be emphasized that the quality of the performance, from the point of view of speed and skill, is a secondary matter.

The Combating of Tuberculosis

A new Prussian law establishes stricter regulations for combating tuberculosis. Heretofore only contagious cases of pulmonary and laryngeal tuberculosis and deaths from these disorders were notifiable, now every death from tuberculosis of any form must be reported, and also every case of tuberculosis of the skin. The notices are to be given to the health officer within one week in the event of illness and within twenty-four hours in case of death. The old regulations provided further that the householders' control committee must report to the proper station any change of residence of such a patient. The new regulations require that any change of residence of a suspected person also be reported. In fact, in general, the new regulations place more emphasis on the suspected patient, for example, they provide that suspected persons may be included in the care-taking measures established for the tuberculous.

The Excess of Females

Before the war there were in Germany 1,029 females to each 1,000 males. After the war this relationship was greatly changed, there having been 1,101 females to each 1,000 males. Gradually, however, the disproportionate number of females has been remedied and recent statistics place the relation at 1,059 females to 1,000 males, while the excess number of male births (1,000 girls to 1,055 boys) appears to be bringing about a further betterment. The present excess of females over males ranges around 1,900,000 and is found almost exclusively in the cities. The excess is largest in Berlin, namely, 1,169 females to 1,000 males. In rural communities the proportion is 1,002 females to 1,000 males, and in many small communities a considerable excess of males may be found. The older age groups present the highest excess of females.

BELGIUM

April 26, 1934

The International Association of Preventive Pediatrics

The third conference of the Association internationale de pediatrie preventive was held in Luxemburg, under the chairmanship of Mr Rischard, assisted by Professor Tailens of Lausanne and Mr Daniel Oltramare of Geneva. The first topic, "The Prophylaxis of Infantile Paralysis," was presented by Messieurs P. Rohmer and de Willemm-Clog of Strasbourg, who suggested the following: Early detection and isolation (and specific treatment) of all cases of poliomyelitis, including the abortive cases. Prophylaxis applied to all the children by means of convalescents' serum or the blood of adults. In time of epidemics, the creation of a central medical organization for the application of preventive measures, disinfection measures, sanitary supervision of the sale of food products. Measures to prevent the dissemination of infection: prohibition of all public gatherings. Compulsory notification of the disease, also of sporadic cases, in all countries.

Prof. Arvid Wallgren of Goteburg pointed out that the infective agent in poliomyelitis appears to have a wide distribution. Its distribution is more widespread than the frequency of the disease would lead one to suppose. The infection provokes but rarely clinical symptoms. In this respect, poliomyelitis resembles to a certain extent the chronic infectious type of tuberculosis. The prophylactic measures may be divided into two kinds: those designed to prevent contagion and those directed toward the prevention of the disease by persons exposed. Prophylaxis of exposure has two principal tasks to perform: (a) checking of the dissemination of the infective agent, and (b) prevention of the reception of the infective agent by man. The fact that only a small proportion of the persons exposed come down with the disease shows the great importance of predisposition with regard to the consequences of an infection. Resistance to the disease depends on (a) certain specific factors of biologic immunity and (b) certain constitutional and physiologic factors.

The congress reached the following conclusions: Since infantile paralysis is due to a micro-organism that is still unknown, there are still many obscure points in its etiology, consequently it is difficult to adopt categorically certain prophylactic measures. The little that is known appears, however, to justify the following attitude: infection may develop either by direct contact from child to child or through the mediation of nonparalyzed but nevertheless infected patients or of healthy germ carriers, or, from water or certain foods, more particularly, milk and milk products. In case of epidemics, one should apply the following measures:

1 Compulsory notification of the disease, including sporadic cases, should be introduced in all countries in which such a provision is lacking.

2 It is recommended that the organization of the crusade be entrusted, in case of an epidemic, to a medical service specially created for this purpose, in charge of a qualified physician who will decide on the measures to be taken and will direct their application. He should collect from the infected area all items of information gathered during the epidemic, with a view to their future scientific utilization. He should attach to himself a number of competent physicians and should offer the service of this body to the medical corps to aid in the detection of cases and the application of treatment, including prophylaxis.

3 The first measure to be applied is the early detection and isolation of all cases (including those of the abortive type) under the best possible conditions. Provision should be made for the disinfection of dwellings, personal belongings and excrements.

4 All necessary measures should be taken to prevent dissemination of the disease by water, milk and foods, special attention should be given to the supervision of commerce in food products.

5 Since in epidemics the infection appears to extend to the major part of the population, it is recommended that specific seroprophylaxis be studied and possibly applied in some form that the present status of science places at our disposal. It is advisable that large supplies of convalescents' serum, and possibly of other specific serums, be kept on hand in certain centers.

6 Germ carriers are, in the opinion of most authors, numerous in the infected regions and may be regarded as an important source of infection. Public assemblages of all kinds that might bring about a contact of persons of other regions with the inhabitants of the infected region should be prohibited. In the region invaded by the epidemic, camps and vacation colonies for children coming from other sections should not be established. With the same object in view, all movements of nomadic groups should be prevented. These principles should be kept in mind also in the movements of troops.

7 With regard to closing theaters, schools, consultation centers for mothers and infants, and the like, it is impossible to establish uniform rules. It is advisable to regulate these matters according to the special conditions surrounding each epidemic.

Prevention of Acute Disorders in the Nursing

The second topic before the conference was "Prophylaxis of Acute Specific Disorders in the Nursing." Professor Rott of Berlin presented a paper on "Significance, from the Social Hygiene Standpoint, of Influenza in Preschool Children." Prof. G. Frontali of Padua spoke on "Prophylaxis of Influenza in Early Childhood." The following conclusions were accepted by the congress: For the prophylaxis of acute disorders of the respiratory passages, associated with seasonal or epidemic influenza of early childhood, two kinds of measures are proposed:

MEANS OF AVOIDING CONTAGION

Means of avoiding contagion. In groups of children under institutional care, in cubicles, after rigorous elimination of all notified cases of other infectious diseases, the creation, in waiting rooms of consultation centers for children, of smaller apartments making it possible to keep children separate before consultation. Application to the infant wards of modern methods of air conditioning and the maintenance of a suitable temperature at all seasons of the year. All members of the personnel to report at once the slightest rhinopharyngeal disorder. The use by the personnel of a simple mask, at least with the appearance of the first symptoms, and the regular examination of the personnel to exclude from service all cases of influenza as soon as they appear. The application of these measures to every person coming to visit the children, and, if possible, the rule that children may be seen only through a glass partition. Impressing on the mothers the importance of their own rhinopharyngeal disorders from the beginning, for the health of the children, and the value of their wearing a protective mask when they nurse and care for the child.

MEANS TO STRENGTHEN A CHILD'S RESISTANCE
TO RESPIRATORY INFECTIONS

While still seeking means of immunization, one must not rely too much on their action in the present state of our knowledge of chemical agents. An endeavor should be made to acquire a better knowledge of the influences of weather. The physician should be instructed as to the importance of a well adapted diet, with emphasis on breast feeding, and if that is impracticable, the need of a complete and well balanced diet. Lyons was selected as the meeting place for the next session.

Marriages

HENRY KELSO CUNNINGHAM, Knoxville Tenn, to Miss Marie Russell Nninger of Roanoke, Va, June 9

HERBERT E MOORE to Miss Margaret Winstrom both of Birmingham, Mich, in May

JOSEPH F CARROW, Cadillac, Mich, to Mrs A L Dryer of Marion, June 3

HARVEY GARRISON JR, Jackson, Miss, to Miss Merideth Owens, April 25

CLYDE JOHN GEIGER to Miss Frances Ferry, both of Chicago May 26

Deaths

Joseph John Meyer ☉ Johnstown, Pa, Jefferson Medical College of Philadelphia, 1915, past president and secretary of the Cambria County Medical Society, member of the House of Delegates of the American Medical Association in 1931 served during the World War, on the staff of the Municipal Hospital and formerly on the staffs of the Conemaugh Valley Memorial and Mercy hospitals, editor-in-chief of the *Medical Comment*, aged 41 died May 8 of lobar pneumonia

Robert Lewis Richard ☉ Santa Barbara Calif Medical College of Ohio, Cincinnati, 1894, member of the American Psychiatric Association, was appointed assistant surgeon in the M C, U S Army, in 1903, promoted to captain in 1908 and resigned in 1912, at one time lecturer in psychiatry at the University of California Medical School San Francisco formerly superintendent of the Mendocino State Hospital, Tamage aged 64, died, May 25, in Los Angeles

Charles McPherson Curtis, College Park, Ga Southern Medical College, Atlanta, 1887, member of the Medical Association of Georgia, formerly mayor and councilman of College Park, for many years member of the school board and the Georgia Military Academy, aged 68, died May 6, of heart disease, following an operation for appendicitis

Alexander Marcy Jr, Riverton N I University of Pennsylvania School of Medicine, Philadelphia, 1881 member and past president of the Medical Society of New Jersey member of the House of Delegates of the American Medical Association in 1905 and 1911, formerly bank president aged 75 died, May 1

Robert Wallace Haddon ☉ Chicago, Harvard University Medical School, Boston, 1893, for many years professor of general and orthopedic surgery, Post Graduate Medical School, aged 68, died suddenly June 1, in the Post Graduate Hospital of heart disease, following an operation on the gallbladder

Mary Biddle McCollin Tatum, Radnor, Pa, Woman's Medical College of Pennsylvania, Philadelphia 1889, aged 66 senior member of the board of managers of the Woman's Hospital, Philadelphia, where she died, May 10, of acute suppurative appendicitis with peritonitis

Carl Richard Wagner ☉ Pasadena, Calif Rush Medical College, Chicago, 1921 fellow of the American College of Surgeons, on the visiting staff of the Pasadena Hospital aged 36 died, June 8 in a local hospital of injuries received in an automobile accident

Harvey H Martin ☉ La Porte, Ind, Chicago Homeopathic Medical College 1895, fellow of the American College of Surgeons, served during the World War surgeon to the Holy Family and Fairview hospitals aged 62, died May 27 of heart disease

Charles Henry Francis O'Neill, New York College of Physicians and Surgeons in the City of New York, Columbia University, 1894, member of the Medical Society of the State of New York, aged 64 died suddenly May 10 of heart disease

Paul Elias Kuhl ☉ Trenton N J, University of Louisville (Ky) School of Medicine 1907 on the staff of the Mercer Hospital aged 50 was found dead, April 19, of illuminating gas poisoning, self-administered

Mary Pearlee Manning, Hamilton Ohio Miami Medical College Cincinnati 1904, member of the Ohio State Medical Association public school physician aged 70 died April 11 of pneumonia

Horatio Pilkington, Philadelphia University of Pennsylvania School of Medicine Philadelphia 1879 member of the Medical Society of the State of Pennsylvania aged 78 died March 1

STANDARDIZATION OF DIGITALIS

To the Editor—Recent correspondence in *THE JOURNAL* (March 17, p 862, April 14, p 1246) regarding the standardization of digitalis leaves impressions that are likely to increase the dilemma of manufacturers

Pharmacologists are largely responsible for introducing, and carrying on the principal investigations in, bio-assays, but the practice of bio-assay is chiefly the concern of manufacturers of pharmaceutical products. The latter require simple, reasonably accurate and economical methods that will give reproducible results. Such methods will increase the popularity and promote the use of bio-assays.

There is no doubt of the frog method being simple, but there is serious doubt of its giving accurate and dependable results. Moreover, frogs are practically unobtainable in arid and semitropical regions and importations are costly, so that an assay on frogs may actually be more expensive than on cats. However, cats too are difficult to obtain in sufficient quantities almost everywhere. Of course, it might be possible to import frog-assayed or cat-assayed digitalis from other parts, but this may not be desired for various reasons. I need not dwell on other difficulties and complications of the cat method, such as the difficult handling of cats, the indispensability of surgical anesthesia and operation, the complex technical arrangements for bio-assay, the considerable individual variability in animals, at least twelve cats being necessary and not six as stated in the correspondence, and the use of death as a single end point. These various phases of the problem of digitalis assay have long ceased to be academic and the search for other methods has continued.

With the object of improving the bio-assay of digitalis, and of eliminating the difficulties and complications of the frog and cat methods, Shoemaker and I suggested in 1926, and I definitely proposed in 1929, the use of the pigeon. The pigeon method has not been referred to in the correspondence mentioned, although it has been sufficiently described in well known scientific journals. This is not the place to discuss the details of and results with this method. The following list of references will provide these matters.

The advantages of the pigeon method may be briefly stated as simplicity, reasonable accuracy, and economy. Pigeons are

easily obtained or raised everywhere, no surgical anesthesia or operation is necessary, a result is obtainable in fifteen minutes, the pigeons can be used repeatedly. A check on the results of bio-assay according to the emetic dose can be obtained, if desired, by determining the fatal dose in the same pigeon. Results with the pigeon method compare favorably with those by the cat method. It is possible to use the emetic dose for estimating the probable full therapeutic dose of digitalis (Stockton, 1933) and more satisfactorily than fatal doses according to the frog and cat methods (Dock, Stockton and Lehman, 1933). While this application should be further investigated, the results already obtained are promising enough to indicate that the denial of such possibilities for a bio-assay method in the correspondence mentioned is unwarranted.

In view of all that has been said, it would pay manufacturers to investigate the practical possibilities of the pigeon method for assaying digitalis.

"DINITROPHENOL POISONING"

To the Editor—I should like to make a correction in the article on "Dinitrophenol Poisoning" reported by Drs Jackson and Duvall in *THE JOURNAL*, June 2.

Under the chemical analyses Dr Jackson reported an index of 20 on first examination. At the time the examination was made it was brought to Dr Jackson's attention that the color obtained at that reading was almost entirely dissipated by the addition of 5 per cent hydrochloric acid. This is according to recommendation made by Dr Tainter and his co workers in *THE JOURNAL* of Nov 4, 1933. A second determination could not be made at this time because of lack of serum. The second report of 53 was obtained on later serum (also dark in color), which was decolorized with 5 per cent hydrochloric acid.

I make this correction in order that the report may not be accepted by some as conclusive evidence that liver damage had occurred.

BERTHA L ISAACS, Highland Park, Ill

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted on request.

SENSITIVITY TO POLLENS AND GRASSES

To the Editor—A man aged 24 has had hay fever followed by bronchial asthma for the past several years. The hay fever has begun every year excepting one during the second or third week in August. One year he had a short and mild attack about the third week in July. The attack lasted only about a week but recurred in the latter part of August. He never has asthma until after the onset of hay fever and the latter ceases after one or two hard frosts. He has recently been tested for sensitivity to the usual summer grasses and ragweed being used. He gave a distinctively positive test to each of these. What treatment would you suggest? Please omit name and town. M D, Wisconsin

ANSWER—This patient is one of a large group who is undoubtedly hypersensitive to the pollen of both the various grasses and ragweeds. He is apparently much more sensitive to the ragweeds, as evidenced by more symptoms in August and September, but the fact that he has had trouble in July would indicate that he is affected also by the pollen of the ordinary grasses, such as timothy, orchard grass, red top and June grass. The finding of positive skin tests with the grasses and ragweeds confirm the double diagnosis of hay fever and asthma.

The patient should be treated as follows. For his hay fever due to the pollen of the grasses he should be treated seasonally, as this season has already started. He should be given

intradermal injections every day or every other day beginning with 0.05 cc of a 1:10,000 dilution of a mixed grass extract, followed by cautious increases up to about 0.50 cc. Treatment for grass pollen hay fever should cease about the first of August.

For the ragweed hay fever the usual preseasonal treatment is advisable if started at once. The first dose should be 0.05 cc of 1:10,000 extract of mixed giant and short ragweed. If in the vicinity of Chicago it would be well to add about 20 per cent of an extract of burweed or march elder to the two ragweeds. The second dose should be 0.10 cc, followed by increases of approximately 40 to 50 per cent up to a dosage of about 1 cc. Then 0.10 cc. of a 1:1,000 extract should be used and this increased similarly up to 1 cc. Following this, 0.10 cc of a 1:100 extract may be used, with gradual increases up to about 0.50 cc.

These injections should be given in separate arms so that if any reactions occur the offending extract may be identified. If the reaction is manifested by a severe local inflammation, the last dose should be repeated and no increases should be given as long as local soreness is present. If, as occurs sometimes, a constitutional reaction follows, as manifested by urticaria, hay fever or bronchial asthma, epinephrine should be given at once in dosages of from 0.50 cc to 1 cc of a 1:1,000 dilution and may be repeated if necessary. Such a reaction calls for a decrease of the next dose of pollen extract.

The injections of ragweed extract had best be given three times a week so that a sufficient amount may be reached before the ragweed starts pollinating, about the middle of August. After this period the injections should be kept up but the dose should be reduced to about one half of the highest amount reached. When the season is over the patient may be treated either perennially by giving injections every two weeks throughout the year or treatment may be stopped and begun again about the first of March of the next year with injections of grass and ragweed extracts.

MONILIASIS OF TONGUE

To the Editor—One of my little patients has a case of moniliasis of the tongue which shows itself as a thick grayish white coating. Monilia organisms were found by smear and culture. Treatment with various fungicides (the last one a mixture of benzoic acid and thymol in water) has not given the slightest relief. This condition has persisted for more than a year. Please let me know what you consider the best treatment. An early reply either by letter or in one of the next issues of *THE JOURNAL* would be greatly appreciated. Kindly omit name.

M D California

ANSWER—The question was submitted to Dr B K Ashford, who writes: "Let us consider that all fungicides of value have been unsuccessfully tried. From now on, attention should be devoted to Monilia vaccines made from a seven-day culture the virulence of which one has attempted to exalt by passage through laboratory animals. If one obtains a sore tongue on the third or fourth day after the injection of the third or fourth dose, one can be pretty sure that one is getting a local reaction which would be highly satisfactory. My method of making these cultures is that of Dr Carl Michel, who worked here with me on preparing vaccines for use in sprue. After the usual method of sterilization, he gaged the strength of his vaccine not by counting the organisms in a given amount but by percentage of the sediment to the total fluid, using a 1 per cent preparation. We began with 0.1 cc, increasing the dose by one tenth more at each injection, these inoculations coming once a week. This should be used together with a strong alkaline mouth wash, and if the child is old enough, a diet consisting of animal proteins, fresh vegetables and fruits, excluding sugars, fats and cereals."

BENEDICT TEST FOR SUGAR

To the Editor—Does it matter if suspected urine and Benedict solution are boiled a long time? What other reaction could it be? I find that after prolonged boiling and letting the solution stand there is a yellow precipitate. Please name a new book on urinalysis.

EMIL LOFGREN M D Rockford Ill

ANSWER—The technic for performing the Benedict qualitative test for sugar in the urine is as follows: To 5 cc of Benedict qualitative reagent add 0.5 cc or 10 drops of urine and mix. Heat in a boiling water bath for five minutes or boil over a flame for two minutes while shaking to prevent bumping. A green, yellow, orange or red finely granular precipitate that rapidly settles out indicates reduction. The color depends on the amount of sugar present. If only a small amount of reduction is present, allow the tube to stand or centrifuge it. The mixture changes to green or yellow when

there is reduction. With complete reduction it becomes almost colorless. A flocculent precipitate that does not settle quickly is due to other substances than sugar.

Benedict's solution is less susceptible than Fehling's to reduction by other urinary constituents, as uric acid or creatinine. It is, however, promptly reduced by alkaptonic acids or the conjugated glycuronic acids, as well as by an excess of preservatives such as chloroform, chloral and formaldehyde.

The first time a urine from any patient shows reduction, further tests are indicated to determine whether the substance is sugar, and the kind of sugar.

To be clinically significant, the urine must contain enough reducing substance to reduce Benedict's reagent in the heating time specified. If more than a trace of protein is present, it should be removed by acidifying with acetic acid, boiling and filtering.

An excellent new book on urinalysis is "Urine and Urinalysis" by Gershenfeld (Philadelphia, Lea & Febiger, 1933).

ONYCHOLYSIS

To the Editor—I have a patient, a woman about 30 years of age, who has onycholysis of every finger of each hand. There is no pain nor discomfort in any way and no other objective symptoms except a turning loose or separation of the nail from the nail bed. After the nail has become separated from the nail bed the nail assumes a lifeless and dead color and has no feeling of life in the separated part. The nails of the toes are perfectly normal. The patient came to Nevada from an Eastern state about three years ago and developed the condition about a year after residing here. She had never had the condition before coming to Nevada. The etiology of this condition is obscure as the personal history and physical examination of the patient are negative for any other pathologic condition. I shall greatly appreciate any information that you may give me concerning the etiology and treatment of this condition. I am particularly concerned about the curative treatment if there is such a thing as the patient's finger nails are in a bad condition and she is at all times terribly self-conscious about her nails. As to treatment I have tried numerous things such as soaking the fingers in hot water and painting the nail bed with tincture of iodine but the treatment has been most disappointing and absolutely devoid of benefit. If you are unable to enlighten me as to treatment I shall greatly appreciate it if you will refer me to some authority who you think might give me the proper information. Kindly omit name and address.

M D Nevada

ANSWER—Onycholysis or separation of the nail plate from the nail bed is one of the characteristic nail changes of psoriasis. In this disease there is at the outset an accumulation of keratotic material beneath the free border, which crumbles away or is removed by the patient, leaving a space between the nail and its bed. Another characteristic change is pitting of the nails. It is possible that this case is due to psoriasis limited to the nails. It may also be due to other unknown causes.

The treatment that would offer the best chance of recovery is roentgen therapy, applied over the region of the matrix of the nail. The best result would probably be obtained by giving three fourths of an erythema dose at monthly intervals using either filtered or unfiltered radiation. A maximum of six such treatments may be given.

TREATMENT OF LATE SYPHILIS

To the Editor—I have been treating a case of apparent tertiary syphilis in a man aged 47. I have given him three courses of treatment of nearsphenamine from 0.45 Gm up to 0.9 Gm bismuth compounds and iodides. The treatment has extended over a period of about one and a half years. Frequent Wassermann tests have continued to show a 4+ and the last showed a 3+ reaction. I have just finished giving him his third course and his eighth treatment with nearsphenamine. Would you kindly advise me as to the correct procedure in his treatment? I am much concerned because of my failure to make any impression with this treatment. Please let me hear from you. Kindly omit name.

M D Wisconsin

ANSWER—The crux of the situation here seems to be what is meant by apparent tertiary syphilis. Late syphilis may cause anatomic and functional damage in a number of different domains, particularly the central nervous system and the cardiovascular apparatus. It is impossible to suggest the proper therapeutic course without knowing the details as to the patient's physical condition. If there is no clinical evidence of neurosyphilis or of cardiovascular syphilis and if the examination of the spinal fluid shows no abnormalities, it is reasonable to assume that the patient has either latent or late cutaneous or osseous syphilis. In the latter case the further management of his treatment might well proceed as suggested in *Queries and Minor Notes* in *THE JOURNAL* Nov 4, 1933, page 1500 the query dealing with the treatment of Wassermann fast syphilis. If the patient has neurosyphilis or cardiovascular syphilis, the proper method of management is the treatment of either of these two conditions and details cannot be furnished without more definite knowledge of the particular patient involved.

DIFFERENTIAL DIAGNOSIS OF DISTURBANCE
OF NERVOUS SYSTEM

To the Editor—A man, aged 42 a robust traveling salesman noticed six months previous to consultation a wasting of the muscles a tingling sensation and impairment of strength of his right hand especially noticed when driving or writing. Examination discloses marked atrophy of fat subcutaneous tissue and the adductor pollicis and the first, second third and fourth lumbricalis muscles of the right hand. The right arm is normal and has the same size and strength as the left arm there has been no injury and he has always been right handed. Repeated physical and laboratory examinations have been negative. The reflexes are intact and normal. The Wassermann reaction of the blood and spinal fluid is negative. Blood counts chemical examinations and culture give negative results. The basal metabolic rate is normal. The patient had a tonsillectomy seven years ago previous to operation he had several attacks of acute tonsillitis. What is your diagnosis prognosis and what treatment would you advise? Please omit name and address

MD Florida

ANSWER—The possible diagnoses to be considered include degenerative changes in the anterior horn cells of the cord, either an amyotrophic lateral sclerosis or a progressive muscular atrophy, or pressure from a syringomyelia or a neoplasm. In the former there are typically no sensory symptoms, though some feelings of numbness may occur, these conditions usually are symmetrically distributed on the two sides of the body. With pressure in the neighborhood of the anterior horns there is usually some pain and hyperesthesia, which are often severe but may be absent in the latter case there will usually be loss of pain sensibility, often without loss of tactile sensibility, of segmental distribution. The degenerative lesions are usually progressive and spread to involve other levels of the cord, often progressing to the medulla and causing a bulbar paralysis. No remedies seem to have much effect in arresting the disease though the administration of increasing doses of strychnine has been advocated. In the pressure conditions it is possible that surgical intervention may have good results. The important indication in this case, therefore, is the establishment of a definite diagnosis. A complete neurologic examination is urgently advised.

COLLECTION OF URETERAL URINE

To the Editor—The general practitioner is in need of a simple inexpensive instrument capable of collecting separate ureteral specimens. I have in mind a rubber catheter consisting of three flexible tubes two molded so as to fall opposite each ureteral orifice after insertion, and one molded so that its tip will rest on the floor of the bladder the whole unit to be manufactured in the usual catheter sizes. First is there such an instrument on the market? Second what is the distance between the interior urethral orifice and the ureteral orifice in the average urinary bladder? In the adult? In a child of about 5 years? Third do the ureteral orifices and internal urethral orifice form approximately an equilateral triangle? In an adult? In a child?

ROBERT MONFORT MD Wolverine Mich

ANSWER—There are a number of such instruments on the market, one is the Harris segregator and another is known as the Luys. Neither of them is used to any extent at the present time because of their obvious inaccuracy. From the description given, an instrument of this kind would not seem to be of much practical value. The distance from the internal urethral orifice to the ureteral orifices is about 2.5 cm in the adult. The internal urethral orifice and the ureteral orifices form approximately an equilateral triangle.

BLOODY SEMEN

To the Editor—Will you kindly let me know the possible causes and course of treatment for bloody semen? Please omit name

MD New Jersey

ANSWER—Hemospermia, or the presence of blood in the semen, is most frequently due to a chronic seminal vesiculitis. It should be noted, however, that it is necessary to differentiate between true and false hemospermia. In true hemospermia the blood and the semen are well mixed, since the bleeding occurred in the seminal vesicles, whereas in false hemospermia the origin of the blood is in the urethra, in which case the semen is streaked with blood.

Although this origin of the blood is generally accepted, there are some who believe that the blood may originate in the prostate gland and not in the seminal vesicle, and others believe that the origin of the blood is a chronic prostatitis associated with urethritis. However, it is the opinion of most urologists that the blood in hemospermia originates in the seminal vesicle. In rare instances hemospermia may be due to sexual excess, although this is very exceptional. Stones in the prostate and carcinoma of the prostate rarely produce hemospermia.

In the management of this condition, due consideration must be directed toward the diet, which should be bland. The use

of alcohol is contraindicated. One should see that the bowels move daily and naturally. Sexual excess is to be avoided. The use of heat by rectum has a definite place in treatment. This may be used either in the form of hot rectal irrigations or by means of a prostatic tube. Next in importance to the use of heat by rectum is massage of the vesicles. Massage should be gentle so as not to produce pain or bleeding. Massage should be carried out about once in five days, best with a full bladder. After the stripping, the patient is instructed to empty the bladder. This may be followed by an irrigation of the urethra and bladder with a warm solution of potassium permanganate in the strength of 1:5,000. Or, instead of irrigations, one may use instillations into the deep urethra of a 1 per cent solution of strong silver protein or a 5 per cent solution of mild silver protein. Internally the use of potassium iodide has been recommended.

In order to facilitate drainage, dilation of the deep urethra with sounds or dilators is indicated, and here again manipulations should be gentle. All traumatism must be carefully avoided during instrumentation.

BACTERIOLOGY OF NORMAL ORGANS

To the Editor—Last fall while I was attending a surgical clinic at Cook County Hospital, I heard the surgeon a professor in one of the large medical schools of Chicago state that in cholecystectomy he rarely peritonealized the gallbladder bed unless it was very easily done and did not require a suture being passed through the liver substance for normally and in health the liver is teeming with bacteria. Some time later I had occasion to ask our pathologist his opinion as to the correctness of this statement about the organisms in the liver tissue. His reply was that not only is that true of the liver but of the skin layers, body musculature peritoneum and organs generally. Can you agree to this and is there any literature on this unusual disclosure?

WILLIS P. BAKER MD Santa Ana Calif

ANSWER—To say that the liver and other internal organs in conditions of health are "teeming with bacteria" is gross exaggeration. Apparently occasional bacteria may occur in the liver and other internal organs in health. This question was studied carefully by W. W. Ford (On the Bacteriology of Normal Organs, *J. Hyg.* 1:277, 1901) and he found that in at least 70 per cent of the animals that he studied the organs contained bacteria that were capable of development provided a sufficient time was allowed to elapse between their removal and their final examination. In no case did Ford or any one else find that normal organs were "teeming with bacteria."

ENLARGED THYMUS RADIATION AND THYMIC DEATH

To the Editor—This question must be decided by our medical board which desires to seek the most authoritative information on this important subject. 1 Do you as a routine roentgenograph all children's chests for an enlarged thymus before operation? 2 If this is your practice have the results justified the procedure? 3 If not your practice to roentgenograph all chests do you roentgenograph any and under what circumstances? 4 If not your practice now, did you at any time do this and what was the reason for abandoning this procedure? 5 Have you had any so-called thymic deaths after diagnosing and treating the case by radiation? ALBERT L. VOLTZ MD, Richmond Hill, N. Y.

ANSWER—In addition to answering the questions specified in the query, it seems propitious that a word be said about the present attitude toward congenital enlargement of the thymus. One has only to review the literature to realize that there has been a decided change during the last ten years. Enlargement of the thymus either alone or in conjunction with a generalized adenopathy was considered a usual cause of sudden death in infants and young children. During the last two years this attitude has been changed to the extent that many feel that enlargement of the thymus should never be credited as causing these sudden deaths. Of the more recent contributions tending to explain sudden death associated with enlargement of the thymus, Waldbott (*Am. J. Dis. Child.* 47:41 [Jan.] 1934) reports the pathologic process in thirty-four cases and discusses the observations and their explanation from an anaphylactic standpoint. He feels that allergic studies should be made in all cases in which there is roentgen evidence of an enlarged thymus.

At present it is not customary to roentgenograph all children's chests for enlargement of the thymus before operation. Infants under 1 year of age are usually examined with the fluoroscope or roentgenographed if time permits, and always in the event of any symptoms.

It is probably advantageous to examine all infants' chests with the fluoroscope whether or not operation is contemplated. With proper precautions and in competent hands, the exposure to x-rays necessary to produce shrinking of an enlarged thymus is accompanied by a minimum of risk.

HYPOTENSION AND BLOOD PRESSURE NEUROSIS

To the Editor—I would appreciate an opinion on the following case. A man aged 60 an executive (plant manager), 6 feet 1 inch (185 cm) in height weighing 193 pounds (87.5 kg) who is active and to all appearances and tests is in an excellent state of health three years ago at a routine physical examination in New York was found to have a blood pressure of 120 systolic 80 diastolic. The physician thought it too low and advised tri weekly injections of ampoules of pitressin. This advice was followed out for three months during which time the blood pressure varied from 116/78 to 126/84, being 122/80 when the medication was stopped. With this psychologic background he now has his blood pressure taken monthly and following each test complains of lack of pep an occasional trifling dizzy spell and thinks that something should be done to increase his blood pressure. Please omit name.

M D Canada

ANSWER—From the data given it is quite clear that the patient has developed a phobia concerning his presumed hypotension. The unwise remarks of the physician in New York unquestionably initiated this lamentable neurotic sequence particularly as the stimulus was repeated thrice weekly for several months while he was receiving the totally unnecessary and obviously useless injections. This arterial tension averaging about 121/80, is within the normal limits, and he should feel notably relieved and grateful that it is not higher. There is no reason whatever for ascribing his complaints particularly the "lack of pep," to the status of the circulation. Other possible causes of his apokammosis and slight vertigo must of course, be ruled out. One of the most common conditions found with complaints such as these is a moderate habitual anemia. It would be interesting to note his subjective complaints if he was misinformed that his tension were higher. An active man of 60 cannot and must not expect to retain his youthful energy and endurance indefinitely. Studies of longevity by several large life insurance companies definitely indicate that those with low normal arterial tension have a greater than average life expectancy. It may be that his apprehension is due, in part to a misunderstanding with regard to the significance of the arterial tension, he may possibly feel that his present condition is due to inadequate cardiac strength. Such an explanation is obviously wrong, for the pulse pressure is quite adequate and nothing was stated about tachycardia or undue distress on exertion. Every possible effort must be made to convince him of the entire normality of his circulation and of the unwise ness of his anxiety.

ETHER AND SURGICAL SOLUTION OF CHLORINATED SODA IN EMPYEMA

To the Editor—I would greatly appreciate any information you can give me with regard to the efficacy of ether irrigations in empyema when surgical solution of chlorinated soda lessens the purulent discharge but does not entirely eradicate it. Please omit name.

M D Chicago

ANSWER—No especial merit in the use of ether in chronic empyema is known. Surgical solution of chlorinated soda is both an antiseptic and a proteolytic agent. Many empyemas of short duration will stop draining if sterile without obliteration of the cavity. If some secretion continues it is usually harmless if sterile but, if infected, reoperation is necessary. When the pleura is markedly thickened, sterilization is difficult and surgical collapse with obliteration of the cavity is usually necessary. The important thing is to keep the drainage wound open until either the cavity is sterile or the lung has expanded so that the wound can heal from the bottom out. The tubes must not be too long for the cavity. The size of the cavity may be determined from time to time by taking a roentgenogram after filling with a liquid opaque substance that will not block drainage. Most of the drained empyema cavities will heal without any irrigation whatever. General nutrition and breathing exercises are valuable.

PREOPERATIVE AND POSTOPERATIVE MANAGEMENT OF GOITER WITH AURICULAR FIBRILLATION

To the Editor—I should appreciate a statement as to the preoperative medical management of a woman aged 63 with adenomatous goiter of several months duration. She has a moderately enlarged heart and auricular fibrillation. The apex rate is 145 and the pulse rate 100. There is moderate hypertension. The liver is moderately enlarged as a result of cardiac decompensation. There is a moderately elevated basal metabolic rate of plus 30 to plus 40. Please omit name and address.

M D Massachusetts

ANSWER—Compound solution of iodine 28 cc a day, should be given continuously until a month after operation. Subtotal thyroidectomy should be in one stage after the greatest cardiac improvement has been obtained by all the usual therapeutic measures. This may not be for five or six weeks. The primary period of lowest metabolic depression under the iodine,

occurring at about two weeks, should be passed by in favor of the later time, when the heart and circulation will be in the best possible condition. Digitalis, absolute bed rest, opiates and diuresis should be used to restore compensation. Conversion of the heart to a regular rhythm is not necessary before operation. It may occur spontaneously postoperatively or be hastened by giving quinidine.

COLDNESS OF SKIN IN LOCALIZED AREAS

To the Editor—Kindly advise me as to the probable cause of coldness of the skin over the anterior surfaces of the thighs and posterior surfaces of the calves of both legs. The sensation of cold necessitates the wearing of woolen hose and underwear, but this does not relieve the sensation of chilliness even in a heated room. The patient is a man aged 52 robust active and in the best of health as proved by several complete physical examinations. He has not been confined to the house from illness for the past thirty years and has no other complaints aside from these localized areas of coldness. Is this a circulatory condition or neurotic and what measures should be instituted to relieve the condition aside from massage infra red therapy and exercise? Please omit name.

M D Ohio

ANSWER—The possibilities are various, but in the absence of signs of spinal cord or neuritic changes the symptoms described are most likely circulatory in origin. Treatment should be directed at the improvement of the general circulation, perhaps with the use of small doses of digitalis. An attempt may also be made to relax and dilate the vessels with phenobarbital or small doses of the nitrites, preferably bismuth subnitrate, 0.65 Gm, three times a day.

NERVE INJECTION FOR NEURITIS

To the Editor—Please give me details of technic of the hypodermic injection for a localized neuritis over the fifth or sixth lumbar region. Give strength of alcohol and amount and if more than one injection. Please omit name.

M D, Missouri

ANSWER—A neuritis localized over the lower lumbar dermatomes is best and most safely treated by the injection of physiologic solution of sodium chloride or of 0.5 per cent solution of procaine hydrochloride in physiologic solution of sodium chloride into the sacral canal. A spinal puncture needle is introduced obliquely between the two sacral cornua so as to pierce the sacrococcygeal ligament and is then directed sharply upward for several centimeters into the epidural space of the sacral canal. From 50 to 80 cc of fluid is injected. Under no circumstances is alcohol to be used in this locality.

ANALGESIC FOR GALLSTONE COLIC

To the Editor—Will you please tell me whether or not there is any drug the action of which may be depended on to relax spasm in a patient who has recurrent gallbladder attacks? These attacks while infrequent, are very severe and often necessitate from one half to three fourths grain (0.03 to 0.05 Gm) of morphine. Atropine cannot be used because of idiosyncrasy. Morphine pantopon and codeine cause violent nausea which lasts from twenty four to forty-eight hours. The barbiturates allonal and sodium amyltal have been tried with little or no success. Any information or help you can give me along this line will be appreciated. Please omit name.

M D Pennsylvania

ANSWER—Sometimes a combination of analgesics acts more powerfully and with fewer side effects than any one of them alone. For instance gallbladder colic as well as renal colic can often be relieved by

Extract of hyoscyamus	0.15 Gm
Phenobarbital	0.50 Gm
Codeine phosphate	0.50 Gm
Amidopyrine	5.00 Gm

Mixed and divided into fifteen capsules, one being taken with hot water every two hours, as required for pain.

IMMUNITY IN UNDULANT FEVER

To the Editor—Is a person who has undulant fever immune to another attack? Is there any method of immunizing one against this disease? Perhaps you can also advise me concerning a veterinarian who feels that he would give up his profession if he should be liable to another attack.

H R MAYER M D Falls City Neb

ANSWER—It is generally considered that one attack of undulant fever confers lasting immunity. The few reported instances of possible reinfection should probably be interpreted as recurrences. Immunity following vaccination has been reported by a few investigators, notably Nicolle and Conseil. Many veterinarians apparently acquire immunity without the development of clinical symptoms of the disease.

Maine March Report

Dr Adam P Leighton Jr, secretary, Board of Registration of Medicine, reports the written examination held in Augusta, March 13-14, 1934. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Six candidates were examined, all of whom passed. Three physicians were licensed by reciprocity and one physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Ioyola University School of Medicine	(1933)	86 2*

Book Notices

The Relief of Pain in Childbirth By F. Neon Reynolds MCOG
FRCS Hon. Obst. Surgeon to the Hospital for Women and Children
Harrow Road, Cloth Price 10/6 Pp. 114 London: Medical Publica-
tion Ltd. 1934

In this monograph the author first takes up preliminary details that he considers of great importance for the relief of pain during labor, namely, the treatment of the more common mental and physical discomforts. He points out the different requirements in the first and second stages of labor and considers in detail a few methods of producing relief in each of these stages of labor. For use in the first stage the author takes up (1) morphine and scopolamine, (2) tribrom-ethanol (avertin), (3) the barbiturates (nembutal, pernocton and sodium amytal), (4) paraldehyde and (5) nitrous oxide and oxygen. For relief in the second stage, he analyzes the advantages and disadvantages of (1) nitrous oxide and oxygen, (2) chloroform, (3) ether and (4) evipan. The author concludes that complete morphine-scopolamine narcosis involving repeated doses of scopolamine is a complicated procedure entirely unnecessary for the average labor. However, a single dose of morphine and scopolamine, given when labor is well established is undoubtedly the safest and most efficient analgesic for the early hours of a primigravida's labor. Tribrom ethanol has minor difficulties of administration and produces inconsistent results, hence the author does not advise this method. He dismisses the barbiturates for routine use because they are dangerous drugs. However, he considers paraldehyde an almost ideal drug. It is perfectly safe for primiparas and multiparas at whatever stage of labor it is given. There is a wide margin of safe dosage, its preparation is easy, and it requires simple apparatus for its administration which can be carried out by any one skilled in giving an enema. It does not prolong labor and has no ill effects on mother or baby. For the second stage of labor the author believes that nitrous oxide and oxygen is ideal as regards safety and efficiency, but to produce these effects it is necessary to have a skilled anesthetist with expensive and cumbersome apparatus. He therefore considers chloroform the only alternative for use during actual delivery and the preceding hour or so. This drug is well tolerated by the pregnant woman, is an extremely efficient analgesic and anesthetic is not bulky, is cheap and is easily administered. The disadvantages consist almost entirely of factors that are under the control of the administrator. In spite of what the author claims for chloroform, it is seldom used in the United States and properly so. Even with skilled administration there is danger of fatal, delayed chloroform poisoning after its prolonged use or in susceptible individuals. The book is timely because of the numerous attempts at present to find new analgesics and anesthetics, not all of which are safe.

Notes on the Medical Treatment of Disease for Students and Young Practitioners of Medicine By Robert Dawson Rudolf C.B.E. MD
F.R.C.P. Professor of Therapeutics in the University of Toronto Fourth
edition Cloth Price \$4 Pp. 540 Toronto: University of Toronto
Press 1934

The aim of this little book, which now appears in its fourth edition since 1921, is to impress on the student and young practitioner the broad principles of the medical treatment of the sick. It is therefore not to be expected that it would cover exhaustively even the frequently encountered diseases with which it deals or that it would delve deeply into the details of special treatment. The latter are, indeed, as stated in the preface "largely omitted or only hinted at." Nevertheless one cannot but wish at times that a few more of them had been given rather than so many statements of a general nature which can be of little direct help to a reader seeking to learn just what to do in a given case. The following is typical (p. 276): "Lately copper has been used as an adjuvant to iron. Small doses of the sulphate are employed." One may conceivably wish to know just what constitutes a small dose of copper sulphate in the circumstances. Queer allocations of space are also not infrequent in the book, as witness (a) Nothing more definite is presented on the newer preparations

of liver and stomach in the treatment of pernicious anemia than the following (p. 281): "Extracts of liver for intramuscular or intravenous use have now been prepared by many workers and promise well. Farquharson [reference] has lately published an encouraging report of their use intramuscularly. An extract of the stomach has the same beneficial action and is now often used instead of liver." But more than two pages is devoted to the use of arsenic in this disease, including a recommended dosage for atoxyl. (b) The treatment of varicose veins is quickly dismissed as being a surgical matter, but the discussion of peritonitis and appendicitis covers together about eleven pages. (c) There are two full pages of iodide therapy in syphilis, only ten lines devoted to bismuth compounds—though to be sure this is three lines more than is given to the raw meat diet, including horse flesh, in the therapy of pulmonary tuberculosis. (d) A ten and one-half page special treatise on the therapeutic use of oxygen is to be found but not one single mention of the oxygen tent, though the writer does state that he saw the oxygen chamber in use at Cambridge in 1919 (p. 301), "where Dr. Barcroft and his assistants were experimenting with it." (e) In connection with Addison's disease there is a more or less correct but nevertheless entirely unnecessary discussion of the general pharmacologic effects of epinephrine. (f) The often effective, though to be sure somewhat difficult, ketogenic diet in epilepsy is discussed as follows (p. 513): "Fits are often stopped by starvation and as this produces acidosis and ketosis it has been suggested that a high fat diet might be of value, and several physicians report good results with this regime [reference]." (g) As specific remedies in amebic dysentery the author discusses only ipecac and its derivative emetine, save for a four-line reference to a brand of chiniofon, of which he says (p. 396) "lately good reports are appearing." The authorities cited with regard to ipecac wrote in 1922-1923.

On the whole it is probable that the grievous faults of this book are solely ascribable to the plan which has been rigidly followed of discussing in fixed order matters of diagnosis, environment, diet, specific treatment and symptomatic treatment in connection with each of a selected list of diseases. Such a formula must force the inclusion of much that is mere space filling just as inevitably as it results in the conspicuous absence of many things of great importance.

Die diätetische Behandlung der Allergie bei Inneren Erkrankungen
von Dr. Carl Funk, Chefarzt der Abteilung für Allergie und Ernährungs-
krankheiten am Elisabeth Krankenhaus Köln Hohenlind Paper Price
2.40 marks Pp. 92 Leipzig: Johann Ambrosius Barth 1934

This work is propaganda on allergic diets. One fourth concerns the most obvious allergic potentialities of foods. The author is indignant at fats, beverages and cheese and relatively shrugs his shoulder at fish and nuts. One eighth of his effort is lavished on the dietetic management of such conditions as acute and chronic gastritis, hypo-acidity, hyperacidity, enteritis, dyspepsia and colitis in allergic individuals. A legitimate eighth spends itself on various diets and so-called cures. One sixth is set aside to consider specific dietetics of specific allergic diseases, and most of the pages are squandered on such sterling allergic worthies as gout arthritis, epilepsy, essential hypertension and acquired hypersensitiveness in the nature of arsphenamine reactions. In the remaining third of the monograph the author propounds his conception that food allergy resembles the sensitization produced by bacterial reinfection, that a good food is one susceptible of being assimilated into the body economy without becoming a foreign protein, and that the basis of all allergic diets should be a dietary poor in animal protein.

Even the enthusiastic American allergist will protest. Where is the proof of these pronouncements? There is no mention of skin tests. Although skin tests have honest limitations that are recognized by the seasoned unbiased scientist, much of the concrete evidence incriminating foods as etiologic factors was originally based on skin tests.

The unfortunate German genius for antagonizing runs comically rampant through this work. In the old days these writers simply ignored American priorities, if, indeed any reference was made. In Funk's book too Rowe's elimination diets

are mentioned only to be belittled for any German use. Rowe's name and the names of other non-German authors are omitted from the bibliography, while Urbach, quoted in the same passage, finds a place. In the portion of the book concerned with foods in general, the most ludicrous attacks are made. Only blind egotism would cast suspicion on French red wines while absolving those of German origin. The author says "When butter is at least compatible, why not German butter instead of foreign oil?" Only such an author could denounce Camembert cheese with an exclamation point. Scientific writing should not be prostituted to political propaganda.

Children Inc. The Post War "Administration" of the Whole Child Life of One Baltic State in Its Critical Period. A Factual Narrative. By Thomas J. Orblson. Chief of Latvian Section American Relief Administration Child Fund. Cloth. Price \$2. Pp 294 with 6 illustrations. Boston: Stratford Company 1933.

During the period of postwar rehabilitation of the European civilian population, the author, a captain in the medical corps, was made chief of the Latvian section of the American Relief Administration Child Fund. He unfolds the tale of that portion of the gigantic relief project with which he was connected, in a simple style that is easy to read. The enlistment of the Women's Committee to his aid and the handling of the local political factions speak for the diplomatic acumen of the author. The chapter on the siege of Riga by the German-Russian White Army is an excellent portrayal by an eye witness of a dramatic incident. The author gives an interesting account of his experiences in postwar child welfare.

Studies on Gonadotropic Hormones from the Hypophysis and Chorionic Tissue with Special Reference to Their Differences. By Christian Hamburger. Acta pathologica et microbiologica Scandinavica Supplementum XVII. Paper. Pp 184 with 33 illustrations. Copenhagen: Levin & Munksgaard 1933.

This excellent monograph is a record of the author's experimental studies carried out during 1930-1933 in the University Institute for General Pathology, Copenhagen, on materials from exclusively human sources; it was translated from the Danish by Dr. Hans Andersen. The experimental work has been comprehensive, the facts rigorously separated from theory, and the deductive part developed in an apparently reasonable manner; the world literature on the subject is treated satisfactorily but not exhaustively.

Dr. Hamburger's principal thesis is that whereas urines of normal men and women do not contain gonad stimulating substances demonstrable by simple injection of the urine into immature female rats and mice, the urines of castrated men and women do contain such substances in relatively large amounts (confirming the observations of Fluhmann in 1929). The gonad-stimulating substances of castrate urines, however, are different from those contained in the urines of pregnancy.

Routine methods of injecting untreated urines, or the alcohol precipitate of the active substance, are given and the author describes with meticulous care the animal responses to these substances (ovarian uterine, vaginal smears), from thirty to fifty animals are often used in the assay of urine from one individual. That urines may be compared adequately, they are reduced to the same specific gravity (a dilution factor being avoided) and the alcohol precipitation method is preferred, though doubt is thrown on a quantitative extraction of the active substance. Animals were killed 100 hours after the first of five injections during two days.

A careful comparison of the effects of castrate urines with the urines of pregnancy revealed noteworthy qualitative differences in the effects of gonad stimulating substances contained in each. Castrate urines characteristically caused only follicle stimulating effects and did not produce "blood points" or corpora lutea (except in very rare instances). All follicles were stimulated but all were of the same size. The uterus was hypertrophied but not fluid distended. Pregnancy urines, on the other hand, stimulated only a selected few follicles and these to a large size, corpora lutea and blood follicles were present and the uterus was usually distended by fluid. The size of ovaries, following castrate urine treatment, were roughly proportionate to the dosage, which does not hold for pregnancy urine effects. Zondek's mouse-rat unit of sensitivity to pregnancy urines was confirmed, as 1 mouse unit equals 5 rat

units, but in castrate urine injections the mouse is more sensitive than the rat, the ratio being 1 mouse unit to from one-third to one-half rat unit.

These and many other lines of evidence lead to the conclusion that the substances in castrate urines differ from those of pregnancy urines, and since implantation of fresh human hypophyses gave responses similar to those from castrate urines and different from those of pregnancy urines, the author marshals a strong line of evidence and argument that the gonad stimulating substances in castrate urines are hypophyseal in origin whereas those in pregnancy urines are decidual in origin.

The author subscribes to the notion of the separateness of the follicle stimulating and luteinizing substance of pregnancy urines and hypophyseal extracts but states his own inability, and that of others, to separate them successfully by extraction methods. It is pointed out that the castrate organism can so separate them since castrate urines do not contain appreciable quantities of the luteinizing principle.

The author's experiments demonstrate a synergistic effect between hypophyseal secretions and the gonadotropic principle from the urine of pregnancy of the nature described by Evans, Meyer and Simpson and explained by them as a catalytic effect of the urine factor on the growth hormone. Hamburger, though in agreement on facts, offers a contrary interpretation in which the action is merely one of follicle sensitization by hypophyseal derivatives which is essential before the effect of the urine extract is possible. Hypophyseal derivatives stimulate many follicles, hence the action of the urinary factor results in more corpora lutea (than with the latter alone) with the consequent greater size of the ovaries. He finds the same synergistic effect if hypophyseal substances and the gonadotropic principle from the urine of pregnancy are injected on two separate days, thus ruling out the notion of a catalytic effect.

Extraction of numerous tissues, including malignant and benign tumors, indicates that all malignant and some benign tumors can give rise to follicle-stimulating substances in the urine but that malignant tumors of the genital organs most usually do so. All forms of chorionic tissue appear to cause the excretion of a gonadotropic substance in the urine. Tumor patients fall into two categories in regard to urine: (1) those producing urines that have an action similar to fresh hypophyseal implants in giving predominantly follicle stimulation (carcinomas) and (2) those producing urines containing follicle-stimulating and luteinizing hormones similar to pregnancy urines (teratomas, chorionepitheliomas, hydatidiform moles, or any other chorionic derivatives). Repeated examination of negative urines is recommended, since in castrates the output of these hormones appears variable. They have been detected up to twenty years after surgical or roentgen castrations and after the menopause.

The book is a valuable contribution as a standard for such clinical examinations, for the introduction of methods, for ideas and for new material.

Medicine. A Voyage of Discovery. By Josef Löbel M.D. Translated from the German by L. Marie Slevking and Ian F. D. Morrow. Cloth. Price \$3. Pp 334. New York: Farrar & Rinehart 1934.

The voyage of discovery, with fifteen ports of call, namely, medicine, biology, anatomy, physiology, pathology, pharmacology, cellular pathology, bacteriology, serology, surgery, stimulative therapy, endocrinology, the theory of constitution, psychoanalysis, personality and back again to medicine, is, in brief, the plan of Löbel's book. It is a series of essays under the titles listed and it deals briefly with each of the important divisions of medicine. It presents little or nothing that is new nor does it pretend to, but it furnishes a well rounded summary of the important sciences contributory to modern medicine. It is scholarly without being prosy, entertaining without being superficial. Only one important error mars the book and that is one of translation involving confusion between the terms typhus and typhoid, a confusion that is readily enough understood by the reader who is familiar both with German and English and with typhus and typhoid. For the audience to whom the book is addressed however, it should be made clear that the German typhus is the English typhoid. This is the kind of book on medicine which well informed lay persons may read with pleasure and profit. It should promote a better appreciation of

medical science on the part of the intelligent lay public. It should also be excellent supplementary reading for such cultural courses in science as aim merely at giving a general acquaintance without delving deeply into technicalities. The style is fresh, interesting and vigorous. The book is well made and well indexed.

Handbuch der Chemotherapie. Von Dr. Viktor Fischl, auswartiger wiss. sachstf. Mitarbeiter der Schering-Kahlbaum A. G. Berlin und Prof. Dr. Hans Schlossberger, Mitglied des Reichsgesundheitsamtes Berlin. Dahlem, Teil 2. Metallidderivate. Paper. Price 35 marks 89 marks for the 2 volumes. Pp. 350 898. Leipzig: Fischers medizinische Buchhandlung, 1934.

This volume completes a veritable Baedeker through "Paul Ehrlich Land," a continent opened up to science only a quarter of a century ago and already possessing a bibliography that defies the efforts of any one individual. This result of the fortunate cooperation of the chemist Viktor Fischl and the physician Hans Schlossberger is destined to become, by reason of its thoroughness, the indispensable basis for scientific excursions into this fascinating domain. The present volume deals with the metal derivatives, as the first volume took care of the metal-free organic compounds. As is fit, from a historical standpoint, the treatise on arsenic occupies almost 200 pages or one fourth of this volume, and it boasts of a bibliography occupying more than thirty-four pages in double column.

Coccidia and Coccidiosis of Domesticated Game and Laboratory Animals and of Man. By Elvyn R. Becker, D.Sc., Associate Professor of Protozoology, Iowa State College. Monograph Number 2, Division of Industrial Science, Iowa State College. Fabricoid. Price \$2.50. Pp. 147 with 25 illustrations. Ames, Iowa: Collegiate Press, Inc., 1934.

The coccidia receive much attention because they cause heavy losses in mammals and birds, domestic and wild in the temperature zone. Their role in man is insignificant. Becker's book gives an excellent summary, with helpful host catalogue and bibliography, of the present knowledge of coccidial species, host specificity, life cycles, pathogenicity, immunity, prevention and treatment.

Pharmaceutical Formulas. P. F. Vol. I. Being The Chemist and Druggist Book of Selected Formulas from the British United States and Other Pharmacopaeias Together with Non Official Formulas from Various Sources Including Numerous Descriptions of Practical Methods Employed in the Manufacture of Pharmaceutical Preparations and Other Information of Use to Pharmacists and Manufacturers. Comprising also a Selection of Formulas far known Admitted and Approved Remedies from Former Editions and from The Chemist and Druggist Diaries. By S. W. Woalley and G. P. Forrester. Editor of The Chemist and Druggist. Tenth edition. Cloth. Price 15s. Pp. 1146. London: Chemist & Druggist, 1929.

Pharmaceutical Formulas. P. F. Vol. II. Being The Chemist's Recipe Book of Formulas for Adhesives, Beverages, Cleaning Materials, Culinary and Household Requisites, Horticultural and Agricultural Preparations, Inks, Laxatives, Perfumes, Photographic Preparations, Polishes, Soaps, Toilet Articles, Varnishes, Veterinary Preparations, etc. Including Numerous Descriptions of Practical Methods Employed in Their Manufacture and Other Information of Use to Pharmacists and Manufacturers. By G. P. Forrester, F.C.S. Tenth edition. Cloth. Price 15s. Pp. 983. London: Chemist & Druggist, 1934.

These books constitute a veritable treasury of formulas collected by the editor of the *Chemist and Druggist*. Volume I contains a comprehensive collection of official and nonofficial formulas selected from the British, United States and other pharmacopaeias, hospital formularies and the current pharmaceutical literature. Volume II contains chiefly formulas that cannot properly be classified as medicinal. It includes chapters dealing with perfumes, toilet preparations, dental preparations, household and culinary requisites, horticultural and agricultural preparations, adhesives, paints, stains and varnishes. These two volumes should certainly be in all libraries of pharmaceutical and medical colleges. They would soon repay for their purchase in almost any one of the larger and busier retail pharmacies. To illustrate the thoroughness with which many of these topics are treated, one might turn to the chapter on perfumes which extends over almost a hundred pages giving one a veritable introduction into the secrets of the production of bouquets and essences from handkerchief perfumes and toilet waters to sachet powders and perfumed cards and papers. The art of combining synthetic perfume constituents is discussed in practical detail as are also the ingredients required for 'fixation' of perfumes such as musk and ambergris. To review these books in detail is as impossible as to review a dictionary.

Lacidose et l'insuffisance rénale aiguë chez le nourrisson. Par Max M. Lévy. Paper. Price 15 francs. Pp. 103. Paris: Masson & Cie, 1932.

In this short manual the author reviews the theories on acidosis and alkalosis in infancy and points out the practical application in various clinical conditions. Examinations of the alkali reserve of the blood and acidity of the urine in pyloric stenosis, acute renal insufficiency and other conditions are given, with examples. The author advises the administration of sodium chloride in hydrochloremia and the injection of sodium bicarbonate in hypochloremia. The author explains that simple blood determinations will indicate whether sodium chloride or sodium bicarbonate is indicated, but there are probably many other physiologic factors involved, and the whole mechanism is more complicated than the author assumes.

External Diseases of the Eye. By Donald T. Atkinson, M.D., Consulting Ophthalmologist to the Santa Rosa Infirmary and the Alvarado Hospital, San Antonio, Texas. Cloth. Price \$7.50. Pp. 704 with 479 illustrations. Philadelphia: Lea & Febiger, 1934.

A volume of this type limiting itself to external disease of the eye is a distinct contribution to the English speaking physician. The author stresses the lesions of the skin in the neighborhood of the eye and a correlation between ophthalmology and dermatology is established. The numerous engravings help to make the book readable. The author illustrates the lesions adequately with drawings and models. A word of praise must be spoken for one endowed with artistic talent, who has used much time and effort to visualize for others. The references are sadly inadequate for the amount of material covered in the text, they are for the most part ancient and they do not include the available rich supply of relevant foreign literature. Some of the methods described are wholly empirical and others are out of date. A cursory perusal reveals that many of the references are inaccurate. Some of the procedures that are described are lacking in facts, in certain cases actual misstatements are made. Ethylhydrocupreine hydrochloride, a specific drug, is not mentioned in the treatment of pneumococcal conjunctivitis or in the list of antiseptics. The collection of photographs from many ophthalmologists and dermatologists in various parts of the country gives a certain value to the book. The illustrations of operative procedures are better than none at all but are reproduced in a size too small to be of great advantage. The volume covers fully the field it represents.

I Know Just the Thing for That! By J. F. Montague, M.D., Medical Director, New York Intestinal Sanitarium. Cloth. Price \$2. Pp. 265. New York: John Day Company, 1934.

"For patients without doctors and doctors without patience" is the subtitle which perhaps best expresses the respect in which this book is weak. With one or two notable exceptions, attempts to write medical books for both doctors and patients have failed, because the approach to one group is entirely different from the approach to the other. This book is a treatise on constipation and its allied and related ills. There is much excellent material in it, particularly in the first half of the book, but the subject could have been handled more expeditiously and there is a question whether any one afflicted with constipation can be benefited by reading about it to the extent of 265 pages. The book is cleverly written in spots but in general could have been greatly condensed without loss of any essential material. The discussion of vitamins, in which cod liver oil is totally omitted, is inadequate and misleading. It is, on the whole, a useful book but not one to arouse enthusiasm.

Bernardino Ramazzini nel III centenario della nascita (1633-1933). Milano 4 Ottobre 1933. Commissione Internazionale Permanente per la Medicina del Lavoro (sezione Italiana). Società Italiana di Medicina del Lavoro. Paper. Price 6 lire. Pp. 95. Milan: Tipografia Antania Cordani S. A., 1934.

This pamphlet published by the Italian Society of Occupational Medicine, is an interesting review of the work of the great founder of modern occupational medicine. It contains some appreciative messages from Professor Butler of the International Labor Bureau and the lectures by Professor Martin of the University of Lyons, Professor Zangger of Zurich and Professor Oliver of Great Britain, Professor Gudjonsson of Copenhagen and others from leading occupational clinics. The address of Professor Devoto, the 'Grand Old Man' of occu-

pational medicine, Milan, is inspiring. All the other short addresses portray some interesting side lights on the life of this remarkable teacher, whose intuitions on the pathologic lesions induced by various occupations mark him as a clinician of the first order.

Medicolegal

Workmen's Compensation Acts Disability Resulting from Operation to Alleviate Industrial Injury Compensable—The employee sustained a hernia in the course of his employment. Two operations failed to reduce the hernia and the employee was totally disabled. He instituted proceedings before the state industrial commission to recover compensation under the Oklahoma workmen's compensation act. The employer then proffered and the employee submitted to a third operation and the commission continued the proceedings pending the outcome of the operation. The hernia was alleviated as a result of the operation, but in performing it the operating physician transplanted the spermatic cord from its natural position. As a result it was pinched and interfered with in such a way as to cause the cord and the right testicle to atrophy. Later the commission held a hearing in the proceedings that had been continued and awarded the employee compensation for the injury to the testicle and cord. The employer brought an action in the Supreme Court of Oklahoma to review that award.

When an employer has knowledge of the facts of a compensable injury, said the Supreme Court, he becomes charged with knowledge of the extent of disability resulting from the original injury. It was not necessary in this case, to give the commission jurisdiction to consider the evidence on which to base the award, that the employee file a specific claim for compensation for the disability resulting from the third operation. Under the Oklahoma workmen's compensation act, an employer is liable for all legitimate consequences following an accident, including unskilfulness or error of judgment of a physician furnished the injured employee by the employer. An injured employee who submits to an operation tendered by his employer for the purpose of restoring the employee's earning capacity is entitled to compensation for any disability that may follow as a result of the operation. The Supreme Court concluded that the industrial commission had jurisdiction and had properly awarded compensation.—*Skelton Lead & Zinc Co v Bagby (Okla)*, 27 P (2d) 168

Workmen's Compensation Acts Appendicitis Attributed to Septicemia Following Leg Injury—Allen injured his leg in the course of his employment, September 12. The leg became infected and on September 21 Allen was taken to a hospital and an operation performed on the leg. Necrotic tissue and diseased periosteum were removed. After the operation, Allen's condition improved slowly, and his temperature subsided some, although he continued to suffer from pains throughout his body. On October 26 he left the hospital and thereafter was brought daily in an automobile to his physician's office for treatment. On November 20 Allen developed more temperature, became nauseated, and had "general pain" especially in the leg and abdomen. On November 27 he was readmitted to the hospital, suffering at that time with great pain in the lower part of the abdomen, especially in the right iliac region, and suffering at all times with his leg. On the following day an abdominal operation was performed. The appendix and colon were found to be ruptured. The abdomen was full of serofibrinous fluid and a mass of adhesions of the appendix and adjacent parts. Allen reacted badly, improved slowly for two days, and then gradually grew worse until December 3, when he died.

Allen's widow brought suit under the employers' liability act of Louisiana for compensation for his death, alleging that the death was due to septicemia resulting from the leg infection and to lowered resistance due to that infection. The employer and his insurance carrier contended that death was caused by

a ruptured appendix and a general peritonitis which had no connection with the injury sustained on September 12. From a judgment for the widow, the defendants appealed to the court of appeals, first circuit, Louisiana.

The attending physician testified, said the court, that, from September 21, Allen suffered from a septicemia caused by the abrasion on his leg and that his power of resistance was thereby lowered, that the blood stream became infected, thereby infecting the appendix and colon. Two other physicians, called by the plaintiff, concurred in the conclusions reached by the attending physician. Five physicians called by the defendant disagreed with these conclusions, testifying that even if there had been a general infection, which they denied, the subsequent appendicitis and diseased colon had no relation thereto. Allen's death, they testified, was due solely to the delay to operate until after the appendix and colon had ruptured. The physicians called by the defendants, observed the court, had neither seen nor treated Allen. Their opinions were based on hypothetical questions. The opinion of the physician who personally attended the deceased and knew his condition from first hand information was entitled to more weight than the opinions of those who never saw him. *Arcender v Grant Timber Co, Inc* 9 La App 132, 119 So 498. While the preponderance of medical opinion, continued the court, was to the effect that there should have been no delay in operating for the appendicitis the widow must not on that account be denied the right to recover compensation. The physician who had personal charge of the case and first hand information as to the condition of the employee thought the delay was advisable. The opposing opinions were based on hypothetical questions, put to physicians who never saw the patient. Under the circumstances, the court said such a difference of opinion is not ground for defeating a claim for compensation.

Furthermore, said the court, one of the physicians who testified for the defendants was in the employ and pay of one of the defendants. Article 2282, Civ Code of Louisiana, provides

The circumstances of the witness being in the actual service or salary of the parties is not a sufficient cause to consider the witness as incompetent but may according to the circumstances diminish the extent of his credibility.

If, observed the court, being employed by one of the parties is sufficient to diminish the credibility of the witness when testifying to matters of fact, the diminishment must be far greater when such witness is called on to express an opinion based on hypothetical questions. The court then quoted from Greenleaf on Evidence, volume 1, part 3, section 440b, as follows:

In weighing the testimony of biased witness however a distinction is to be observed between matters of opinion and matters of fact. Such a witness it is said is to be distrusted when he speaks of matters of opinion but in matters of fact his testimony is to receive a degree of credit in proportion to the probability of the transaction the absence or extent of contributory proof and the general tone of his evidence.

The court, taking into consideration all the evidence concluded that the accidental injury sustained by Allen September 12, was "indirectly responsible and a causative factor, leading to and bringing about the death" of Allen. The judgment in favor of the widow was accordingly affirmed.—*Allen v Louisiana Highway Commission (La)*, 150 So 98

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Technic of Intestinal Intubation—The technic of intubation, as Miller and Abbott have practiced it, is as follows. The tube with the bag deflated is taken by the fasting subject in the early morning, exactly as are gastric and duodenal tubes, only enough being swallowed at first to reach the stomach, and then, with the subject reclining on his right side, more is introduced slowly until the distal end has reached the duodenum. A little more tube is taken and fluoroscopic observations are made until the capsule has reached at least the third portion of the duodenum. The bag is distended moderately with air or an 8 per cent solution of sodium iodide (to render visualization of the tube and bag easier). After this the subject swallows about 5 cm of tube every ten minutes, fluoroscopic observations being made from time to time until the distal end has reached the desired point. The authors found that within six hours the tube has usually passed along the intestine to a distance of from 120 to 150 cm. beyond the pylorus.

Endocrine Effects of Certain Ovarian Tumors—Novak points out that certain tumors of the ovary, like tumors of other endocrine glands, are capable of highly developed endocrine function. The most clearly defined types are the granulosa-cell tumors and the so called arrhenoblastomas, the latter belonging to the group of testicular adenomas, most often of atypical variety. The granulosa-cell tumors exert a feminizing effect, through the production of theelin by the tumor cells, so that in older women, perhaps far beyond the menopause, they produce most often a hyperplasia of the endometrium associated with periodic bleeding (pseudomenstruation), together with an increase in the size of the uterus. In the few cases seen in young children, they have produced the syndrome of precocious puberty, with precocious menstruation. The arrhenoblastomas, on the other hand, have a definitely masculinizing tendency, as might be expected from the fact that they apparently have their origin from undifferentiated epithelium in the region of the rete ovarii. Under conditions which are not clear, these cells, capable of development along either male or female lines, may assume definitely masculine tendencies, as in the group of tumors under discussion. The relation of this endocrine cause of partial sex reversal to the general problems of intersexuality, sex differentiation and sex reversal is obvious, although knowledge on these subjects is still far from complete. Patients suffering from arrhenoblastoma present in the extreme instances not only such manifestations of defeminization as amenorrhea and breast atrophy but also such evidences of masculinization as a masculine type of hair distribution, deepening of the voice and hypertrophy of the clitoris. The removal of the tumor brings about a regression of these symptoms.

Arteriovenous Fistula Identified by Arteriography—Horton illustrates the importance of arteriography in determining the site of abnormal arteriovenous communications. With the history, the presence of a bruit and thrill over the right thigh and the bradycardiac reaction, the diagnosis of arteriovenous fistula of the acquired type seemed definitely established. The diagnosis was confirmed by the demonstration of a high admixture of arterial and venous blood in the right femoral vein. The site of the fistula could be determined only by means of arteriography, or by surgical exploration. The author believes that arteriography has been used for the first time in his case.

Symptomatic Relief of Emphysema by an Abdominal Belt—Alexander and Kountz state that, in advanced obstructive emphysema, difficulty in breathing is due principally to mechanical factors. The large lungs hold the diaphragm in the position of inspiration and indirectly they also distend the chest to a barrel shape. Respiratory excursion is thereby limited. It has been found that the diaphragm can be pushed upward toward its expiratory position by means of abdominal pressure, properly applied. From this position contraction again occurs. In order to maintain adequate intra-abdominal pressure the authors have devised a belt. In a series of twenty-five patients with advanced obstructive emphysema to whom belts have been fitted, nineteen have been subjectively improved. The average increase in the vital capacity of the lungs has been 39 per cent. With improvement in respiratory function, the characteristically elevated intrapleural pressure of obstructive emphysema has been found to become more negative and thus approach more normal values.

Postoperative End Results in Thyrocarditis—Lahey and Hurthall present evidence to prove that thyrocardiac patients in seemingly hopeless stages of decompensation can by subtotal thyroidectomy not only have their compensation restored but themselves be rehabilitated to a degree that permits normal activities in most of the cases. Their follow-up studies prove that at least 71.5 per cent of patients with auricular fibrillation can be restored to and remain in normal rhythm following the removal of their hyperthyroidism, that the mortality, 4.25 per cent, is relatively low for this serious situation and that compensation is restored and persists in at least 95 per cent of the patients.

Ovarian Hormones in Relation to Cystic Mastitis—Lewis and Geschickter present the analysis of 600 cases of chronic cystic mastitis. There are two types of the disease, one in which cyst formation predominates (referred to as cystic disease of the breast) and the other one in which epithelial hyperplasia predominates (referred to as adenosis of the breast). Their study of the breast tissue of women at various known periods of the menstrual cycle and of pregnancy, and of animals which have been injected with theelin and progesterin combined, reveals that the changes are fundamentally the same. The age period at which chronic cystic mastitis is most common corresponds with the age period at which these two hormones are most active. The tendency of the cysts to vary in size and for the symptoms to be exaggerated in the premenstrual period is an expression of periodic variations of the secretory levels of theelin and progesterin. Undeveloped tubules and acini in the adult breast may respond abnormally during the menstrual cycle and form the basis for the later development of cystic disease and adenosis. Under the intense hormone stimulation of pregnancy, normal development may be resumed. During pregnancy the lesions associated with chronic cystic mastitis disappear frequently. The eventual disappearance of the majority of all undeveloped tubules and acini after repeated pregnancies accounts for the fact that chronic cystic mastitis is rarely encountered in women who have borne many children. These observations also account for the frequent occurrence of cystic disease in married women who have not borne children and in the unmarried. The persistence of these structures through one or two pregnancies accounts for the disease in women who have borne few children. From the study of tissue in experimental animals after the injection of theelin, and theelin and progesterin combined, and of human material obtained

at definite known periods of the menstrual cycle and pregnancy, the authors believe that these changes in the apparently normal breast are due to variation in amount or periodic discharge of the ovarian hormones (theelin and progesterin). Histologically, these changes are not unlike those occurring in cystic disease of the breast and adenosis. Therefore they believe that they are justified in drawing the conclusion that these pathologic states of the breast are caused by alteration in character, amount or periodic discharge of the ovarian hormones.

Incision for Cancer of the Breast—For several years, Bullock has employed an incision in operations for cancer of the breast which starts at the ensiform and extends toward the shoulder to the level of the tip of the coracoid with a varying degree of straightness and obliquity, dependent on whether the growth is in the inner or outer half of the breast, to this is added the transverse elliptic incision of Stewart, or part of it, likewise dependent on the location of the growth. The outer end of this transverse incision is carried well back of the fibers of the latissimus. This forms, when dissected back, two broad based flaps, allows ample exposure of the chest wall and the axilla, is easy to close, does not scar the arm or shoulder and after healing is drawn well outward. A separate stab wound is unnecessary as drainage is established through the back end of the transverse cut. The incisions may be modified in direction and length to meet the requirements of the case. The towel clip grasping an unaffected part used to lift up the breast while its lower surface and the skin in contact with it is printed is left in place. By means of the clamp the breast is deployed in various directions and it is never necessary to touch the breast with the hand.

Acetarsone in the Treatment of Neurosyphilis—Griggs and Schamberg gave intravenous injections of acetarsone to seventeen patients all of whom showed symptoms of neurosyphilis from a clinical or laboratory point of view. Most of the patients improved subjectively, i. e., obtained relief from the radiating pains. The drug seemed to have a tonic effect. One patient gained 15 pounds (6.8 Kg). In most cases the

condition of the spinal fluid was improved. Reports of a favorable action on the Wassermann and Kahn tests of the blood were noted in some of the cases. In two patients with small veins, occasionally a small part of the dose was given extravasously with no untoward symptoms.

Acanthosis Nigricans—Grace and Schwartz report a case of acanthosis nigricans. Frequent clinical observations were made, supplemented by laboratory procedures. The authors believe the case to be one of juvenile acanthosis nigricans in an adult. The clinical symptoms, other than the cutaneous picture, were faintness, fatigability, vague epigastric pains, loss of appetite and a loss in weight of 10 pounds (4.5 Kg.) within seven months. Laboratory examinations revealed a low blood pressure, a high sedimentation rate of the red blood cells and complete achlorhydria. The high sedimentation rate in this case can be accounted for by the presence of a certain amount of fissuring and infection at the base of the overgrown papillae of the axillae, groins and feet or by the condition of the teeth. The weakness complained of may be ascribed to the low blood pressure, and this in turn may follow the exceedingly poor dentition which prevents the patient from having any but the softest foods. There was a diminution of the gonadotropic factor of the anterior pituitary-like substances of the urine, but this was accounted for by the approaching menopause. The only constant observations in the four cases reported by Wieder, Knowles and his co-workers and Burgess is hypo-acidity of the gastric content, and it is possible that this may be significant in acanthosis nigricans, although Bennett and Ryle showed that 4 per cent of normal persons have no free hydrochloric acid in their gastric juice. There is no apparent connection between the acidity of the gastric content and the endocrine system. The "increased sugar tolerance" in Wieder's case is so slight as to be almost within the range of normal. The figures quoted for the basal metabolic and pulse rates in the same case are normal, and the cessation of menstruation in a girl of 13 during the period of hospitalization is scant evidence of ovarian dysfunction. The authors believe that there is as yet no support for the hypothesis of endocrine dysfunction as an etiologic or concomitant agent in juvenile acanthosis nigricans. If juvenile acanthosis nigricans cannot be linked with the endocrine system, the form associated with a malignant process must be considered to be a different disease or the hypothesis of endocrine dysfunction in both forms of the disease should be abandoned. As the clinical and histologic picture of acanthosis nigricans is the same in all cases regardless of the age of onset or of the presence or absence of a malignant process the authors prefer to regard the disease as a single entity and to view as unfounded the hypothesis of endocrine dysfunction as an etiologic agent.

Treatment of Mooren's Ulcer F W Dean Council Bluffs Iowa—p 832

Diabetic and Tobacco Amblyopia—Shannon and McAndrews point out that a person may be a heavy drinker and smoker for years and never notice any depreciation of vision. A diabetic person may go through life and suffer no visual disturbance. However if the heavy smoker and drinker acquires diabetes this relative immunity is apt to change. They report a case which exemplifies this apparent relationship between diabetes and toxic amblyopia. As to the cause of diabetes in this patient they can only guess. Lichwitz and von Noorden believe that persons suffering from alcoholism

are susceptible to diabetes. The authors believe that the case they report is one of toxic amblyopia, precipitated in some way by the onset of diabetes.

Pseudoxanthoma Elasticum and Angioid Streaks—Jacoby reports a case of pseudoxanthoma elasticum and streaks of the retina with the ocular changes illustrated by stereoscopic photographs. It would appear that trauma may be an exciting factor in exacerbations of an already existing disease. Inter-current infections elsewhere may be hastening factors in senile elastosis but they are not necessarily the true etiologic factors. The stereophotographs seem to establish definitely that the streaks are due to veins which have undergone modification in an altered collateral circulation.

Vectors of Relapsing Fever—From the point of view of arthropod vectors, Hearle discusses an outbreak of relapsing fever, recorded by Palmer and Crawford as the first occurring in Canada. The common "wood tick," *Dermacentor andersoni* Stiles, suggested by the authors, is discarded as a possibility in the particular cases cited since the period of adult activity of this species in British Columbia is from March to May, whereas the cases occurred mainly in late July and August, long after this tick has estivated. Other native ticks commonly attacking man are unknown in this part of British Columbia, and the suggestion is advanced that one of the well known Argasine vectors of the spirochete, such as *Ornithodoros talaje* or *O. turicata*, may have been introduced from the southwestern part of the United States or from Mexico. *Argas persicus* is recorded from Canada for the first time and new hosts are recorded for *Ixodes auritulus* Pack rats, *Neotoma cinerea*, are discussed as possible factors in the disease, both as reservoirs for the spirochetes and as hosts maintaining the ticks when the summer camps are untenanted.

Epidermoid Cyst in Bone—Couch states that there is a typical clinical picture of epidermoid cysts in bone. The history, clinical and roentgen observations are so characteristic that a definite preoperative diagnosis can be made. The complaint is of sudden pain over the terminal phalanx, brought about by slight pressure and coinciding with a fracture of the cortex over the cyst. The tenderness persists. The patient usually recalls a rather severe crushing or puncture injury some time in the past and on examination the affected part is found to be tender with one point of maximal tenderness over the fractured cortex. Comparison with the normal side will show a thickening of the phalanx. Roentgenograms reveal a definite clear cut smooth-walled cyst, which produces atrophy and destruction of nearby bone by pressure. The cortex is thin over the cyst and may be lacking on one side. If there is a history of recent sudden pain on slight pressure, a fracture through the cortex will be seen. The presence of the cyst destroys the phalanx, leaving the cyst covered with a thin shell. But it

also must stimulate bone production, for the whole phalanx is larger than normal and gives the appearance of having been "expanded" by the cyst, new bone must therefore have been laid down outside, as it was eroded inside. The most effective treatment is to remove the cyst intact. The advisability of placing a bone graft in this cavity has been considered, but experience has shown that it is unnecessary if the part is protected from further fracture for three weeks. If untreated, the cysts progress and destroy the affected part of the phalanx. They burst through the cortex and spread in the soft tissue, necessitating amputation. They respond to treatment and may be cured with no likelihood of recurrence. The author reports a case of epidermoid cyst in the bone.

Louping Ill in Man—Rivers and Schwenker describe four instances of infection in man that are believed, because of the circumstances under which they occurred and in view of the results of neutralization tests, to represent cases of louping ill. Evidence obtained by the neutralization tests is in favor of the idea that the antibodies against louping ill virus demonstrated in certain serums were most likely the result either of contact with or of infection with the active agent.

Antigenic Potency of Haemophilus Pertussis Extracts—Miller compared the antigenic potency of extracts of Haemophilus pertussis with standard pertussis vaccine. The titer of complement fixing antibodies in rabbits after the injection of these agents was the index used. The observations suggest that fresh extracts of recently isolated strains produce a more rapid rise in titer than does vaccine. The addition of formaldehyde, chinolol and trisresol to these extracts delays the response. Filtration of the extract through a Berkefeld L₂ filter removes the antigen. A more rapid response occurs with the small quantity of extract prepared from a given amount of concentrated bacterial suspension than with the large quantity of standard vaccine prepared from the same amount of concentrated bacterial suspension. Therefore the greater concentration of the antigen in the extract is not the factor responsible for the rapid rise obtained. The unified and

extracellular state of the antigen is the factor responsible. The antigenic component of H pertussis endotoxin is relatively thermostable whereas the toxic component is inactivated by temperatures of 37 C and higher. The author points out that the foregoing data should be verified by further study for they constitute supportive experimental evidence for the trial of H pertussis extract in the prophylaxis and treatment of pertussis.

Etiology of Granulopenia—Kracke and Parker point out that it seems reasonable that a certain proportion of granulopenia is due to arsenamine and a certain percentage to gold salts and perhaps other chemicals, leaving, however, a large group of the idiopathic type with an unknown etiology. The disease is more prevalent among physicians and their relatives, nurses, hospital employees and members of the allied professions than in any other group of people in the United States. It is essentially a disease of the white race. Its distribution is correlated with the usage of benzamine drugs. The authors present eleven cases in which the clinical onset was preceded by prolonged or intensive administration of drugs containing the benzamine group. Statistics are presented to show that this class of drugs has wide usage among members of the medical and allied professions. A hypothesis for its production, based on oxidation reactions of the benzamine drugs, is

presented In the clinical or experimental development of granulopenia, it is necessary to presuppose the existence of a previously weakened, damaged or idiosyncratic bone marrow which may be congenital or acquired The authors urge that all who have the opportunity to study cases of granulopenia should direct their attention to a careful history of known marrow depressing agents and the usage of benzamine drugs in particular

Cocaine Poisoning as Influenced by Diets—Nedzel performed forty-eight experiments on thirty rabbits Ten animals were kept on oatmeal and water, ten on carrots, and ten on oatmeal, water and carrots The experiments consisted of injections of cocaine into the marginal ear vein of a rabbit The dose of cocaine was 10 mg per kilogram of weight After injection, the animal was observed as long as symptoms were manifest The results show that the animals on the alkali-forming diet and on the mixed diet reacted to the injection of cocaine more or less similarly, though the animals on the alkaline diet reacted more vigorously (two deaths) The animals on the acid-forming diet were definitely more sensitive to cocaine poisoning (four deaths) In general the toxic effects of the cocaine were definitely greater and recovery was considerably delayed It is possible that, in acute cocaine poisoning, the intravenous injection of alkali might be of benefit for the poisoned individual Experiments on animals, to test this question, are called for

Microdetermination of Cholesterol in Blood—Kamlet tried to determine whether the extraction of the cholesterol may be effected at room temperature without the use of complicated extraction apparatus Experiments showed that the cholesterol is quantitatively extracted by chloroform from blood dried on filter paper in two hours at room temperature The following procedure was adopted for the determination of cholesterol in blood On an ordinary 7 cm filter paper preferably ashless, 0.2 cc of oxalated blood, serum or plasma is deposited The paper is worked round until the liquid is distributed evenly over the surface and then it is suspended by means of a thread or wire strung through an unstained area in an incubator at from 35 to 40 C After twenty to thirty minutes the blood is dried The paper is rolled up compactly, folded into quarters and deposited in the bottom of an ordinary 6 by 1 inch test tube Into the tube, 10 cc of chloroform is pipetted, corked and set aside for at least two hours During this period the chloroform should completely cover the folded filter paper In this manner a quantitative extraction of cholesterol from dried blood, serum or plasma is effected without the use of heat, thus avoiding the occasional appearance of an off-color Now 5 cc of the chloroform solution is pipetted into an ordinary test tube Into a similar tube 5 cc of the working cholesterol standard is placed The working cholesterol standard is made by diluting 5 cc of the stock cholesterol standard (stock cholesterol standard 1 Gm of chemically pure cholesterol is dissolved in enough chloroform to make 100 cc of solution) with enough chloroform to make 1,000 cc of solution, 1 cc contains 0.05 mg of cholesterol Both standards keep indefinitely in a refrigerator To each tube 2 cc of acetic anhydride and 0.2 cc of concentrated sulphuric acid are added, stoppered, mixed by inversion, allowed to stand for fifteen minutes in a cool, dark place and compared in the colorimeter Comparison Reading of standard over reading of unknown multiplied by 250 equals milligrams of cholesterol per hundred cubic centimeters of blood The unknown is set at 25 mm and compared The reading of the standard multiplied by 10 gives the milligrams of cholesterol in 100 cc of whole blood, serum or plasma

Surgical Treatment of Hemorrhoids W A Fansler Minneapolis—p 254

Surgical Treatment of Hemorrhoids—Fansler describes a procedure, which he believes, with slight modification, can be applied to any case of uncomplicated hemorrhoids The varicose vessels and their interstitial tissue are removed and at the same time enough of their covering is removed so that no skin tabs or redundant mucosa will be left Sufficient mucosa and skin is left to line the lower portion of the rectum and anal canal so that adequate dilatation may occur for defecation and to avoid a stricture The operation is easily and thoroughly accomplished by leaving the hemorrhoids in their normal position and doing the operative procedure through an especially devised anoscope In no case should the hemorrhoid be everted The hemorrhoid to be treated is isolated in the slot of the anoscope In this position it is freely visible and accessible, and the exact amount of tissue to be removed can be determined before the incision is made A plain catgut suture is placed through the uppermost portion of the hemorrhoid An incision is made from the lowermost part of the hemorrhoid mass to its extreme upper pole A second incision is made laterally and parallel to the first and a V-shaped piece of tissue is removed After the original section is removed the edges of the mucosa are retracted with forceps, and the remaining vessels dissected out until the sphincter muscle and the circular muscular coat of the rectum are exposed freely The cut edges are brought into apposition at a few points with plain catgut suture.

Heat Therapy in Treatment of Syphilis—With the idea in mind that only a small proportion of syphilitic patients can be subjected to diathermy, malaria and heat cabinets, Dennie and his associates elevated temperatures by means of hot baths in an ordinary bath tub. The degree of temperature elevations that they obtained has been striking and though the series of cases is not extensive they show a few markedly favorable clinical results and that temperatures so produced are fully comparable to those attained in heat cabinets, diathermias and electrotherms. The patient is immersed in a tub of water at from 95 to 105 F and the temperature is gradually increased by the addition of hot water. There is a surprising individual variation, both in the degree of heat a given patient can tolerate and also in the length of time he can endure exposure to it. The individual tolerance is definitely built up from day to day. It is this tolerance which must govern the ultimate amount and intensity of heat that is administered. The goal is a bath water of from 105 to 115 F for from ten to thirty minutes. The patient is watched closely as to his pulse and general appearance. At the first sign of distress, anxiety or collapse, the bath is discontinued. Following the bath there is a profuse diaphoresis during which the patient is warmly bundled up. Normal temperature is regained in from thirty to sixty minutes. The patient rests for several hours fluids are forced, and rarely are any untoward effects seen. Usually there is a stimulation of the appetite and a euphoric reaction after several hours. Patients often gain weight under treatment. Baths are given daily if tolerance is satisfactory. The authors state that they used hot baths in a variety of types of advanced syphilis. Most of the cases have been of advanced tabes and tabes with dementia paralytica, but they have also included interstitial keratitis, gummas of the skin, late nodular syphilodermas, Charcot joints and a few visceral syphilids.

Treatment of Dysmenorrhea by Hormone Therapy—Witherspoon believes that the most important cause of primary dysmenorrhea is the result of endocrine imbalance. The aim of treatment is either to counterbalance the excess of the follicular hormone by substituting additional corpus luteum influence or to withdraw this influence slowly, so that the follicular hormone stimulation of the uterus will not be precipitated but will appear gradually. The method of treatment employed was to give daily intramuscular injections, from three to four days previous to the expected menses and from one to two days during the menses, of 250 rat units (1 cc) of follutein. After the period was passed, no treatment was given until just before the next expected period. Of ten patients so treated, the results were satisfactory in seven. In one, slight relief of pain was noted, in the other two patients the dysmenorrhea continued in its severe form. The only untoward symptoms noted were an occasional local reaction at the site of the injections. This could be alleviated by lessening the dosage given or by diluting the amount of injection with an equal volume of sterile physiologic solution of sodium chloride.

Copper Sulphate with Sodium Thiosulphate in Treatment of Trachoma—Rice and his associates used a combination of copper sulphate with sodium thiosulphate intravenously in varying doses as a therapeutic measure in trachoma. In the smaller doses (from 20 to 80 mg, depending on body weight) no change was seen in the pathologic condition of the trachoma. There was symptomatic improvement however, in some cases. In the larger doses (from 180 to 205 mg) there seemed to be some slight effect on the trachoma as well as on the symptoms. In the larger doses advocated by Stastnik there was an undesirable reduction in red blood cells and hemoglobin. It would seem desirable for any one experimenting further with this method of therapy to use caution in giving more than 125 mg of copper sulphate per kilogram of body weight in combination with sodium thiosulphate, and to keep a close check on the hemoglobin. The authors did not secure the striking beneficial results described by Stastnik in any of their cases. This form of therapy did not cause any immediate untoward reactions after any of the intravenous injections, nor was there any undesirable effect on the kidneys that could be ascertained by frequent urinalysis. It seems that the possible dangers of this form of therapy outweigh any slight benefits obtained from it. Certainly it does not compare with the older established methods of therapy.

Schistosomiasis Mansoni—The investigations of Hoffman and his associates indicate that the sedimentation concentration method is superior to the routine smear for the detection of eggs of *Schistosoma mansoni* in feces. It may be employed also as an adjunct to indicate the progress of therapy in schistosomiasis mansoni. It may aid in disclosing the presence of other intestinal parasites. Also some evidence has been advanced to suggest that all antimony compounds do not injure the ova of *S. mansoni* situated within the host.

Solar Irradiation of Children—Dodds and his associates exposed twenty eight children suffering from various orthopedic conditions to solar radiation during the summer months. No clinical ill effects occurred. In no case can it be said that the progress of the patient was retarded as a result of the insolation. The marked improvement in the general condition that followed admission might be attributed partly to a beneficial effect resulting from exposure to the sun. Although the amount of insolation obtained was not the maximum possible, it was sufficient to demonstrate that there is little or no likelihood of producing ill effects due to excessive liberation of vitamin D produced by irradiation of the ergosterol contained in the skin. The increase in the serum calcium and phosphorus which was found to have occurred was within physiologic limits. No signs of toxicity such as have been reported by investigators of hypervitaminosis D have been demonstrated. Taking the combined calcium-phosphorus metabolism into consideration, it appears that on a normal diet doses of vitamin D such as are produced by irradiation cause a greater increase in the blood phosphorus than in serum calcium.

Pyelonephritis in Infancy and Childhood—Griffin performed necropsies in 170 cases of pyuria in infants and children, examining the kidneys histologically in seventy and recording the bacteriologic results in eighty-seven. In twenty-five the formation of agglutinins was studied and in nine complement fixation tests were carried out. *Coliform bacilli* were the organisms most commonly isolated, suggesting that pyuria is due to auto-infection from the intestine. Great specificity to agglutination was shown by the coliform organisms. For this reason only autogenous vaccines are likely to be of benefit. Agglutination of the organisms isolated from the urine with the patient's serum occurred much more commonly in the fatal cases than when the patient recovered. Acutely ill patients whose serum did not agglutinate recovered quickly. Probably the development of agglutinins depends on the extent and severity of the lesions in the kidneys and on the general resistance of the patient. The power of fixing complement did not run strictly parallel to the agglutinating properties of the serum. The morbid anatomic and histologic observations indicate that the lesion is a suppurative nephritis affecting especially the renal cortex and that these lesions may either heal leaving scar tissue or become subacute and show scattered foci of round-cell infiltration. The cortical distribution of the lesions and the relatively infrequent infection of the pelvis and bladder point to a blood infection in most cases.

Phenylhydrazine Hydrochloride in Polycythemia—Kennedy points out that phenylhydrazine hydrochloride has been employed with considerable success in many cases. It has a hemolytic effect and reduces the volume of the blood. It

has been suspected of producing serious toxic damage to the liver and kidneys, but conclusive proof of this change is lacking. Clinical experience has shown that administration is not always devoid of risk for certain types of patients, for example, those more than 60 years of age, with marked arteriosclerosis or advanced disease of the liver, kidneys or other viscera. Its use in such patients should be avoided or attended with special caution and the effect of a dose of $1\frac{1}{2}$ or 3 grains (0.1 or 0.2 Gm) should be watched for several days before more is prescribed. The author reports a case in which four short courses of treatment with phenylhydrazine hydrochloride were given without any untoward effect but a fifth produced a severe hemolytic crisis.

Hemochromatosis—Smith and Blair report a case of bronzed diabetes in which sugar (a trace) was demonstrated in only one specimen of urine. The patient was a girl aged 20 years, with skin pigmentation of considerable depth and of a definite bronze hue, especially on exposed parts. On two occasions she had become so severely jaundiced that the conjunctiva was discolored and cirrhosis of the liver was suspected. At no time was the liver palpable, it had become shrunken and small. During life, a provisional diagnosis of hemochromatosis was made, this diagnosis was verified by the postmortem examination. The cause and the pathogenesis of the rare condition of atrophoderma of the face that was seen in this case are easily explained. The subcutaneous tissues and skeleton grew so rapidly that the skin could not accommodate itself to the increased bulk and became overstretched, as it did at the same time about the hips and thighs. The lesions of the face occurred in the course of about two weeks. They were pinkish at first and paled after some weeks.

Blood Brain Barrier in Infectious Diseases—Friedemann and Elkeles state that the blood brain barrier is localized in the walls of the cerebral capillaries. Its permeability coincides with that of the cerebral capillaries. They discuss the methods for testing the permeability of the blood brain barrier. In their experiments with toxins they used four methods: (1) artificial perfusion of the brain, (2) auxoneurotropic effect, (3) comparative determination of the lethal dose of the toxin by the intravenous and the intrathecal route and (4) identification of the toxin in the brain after intravenous injection. As a result of a critical reexamination of the literature and of their experiments, they have arrived at the conclusion that the blood brain barrier is permeable to cobra venom and lamb dysentery toxin, and impermeable to diphtheria, botulinus and tetanus toxins. The property of the toxins of vibrión Nasik and vibrión El-Tor are not sufficiently known. Of the toxins investigated the ability to pass the blood brain barrier is correlated to electrical charge. Diphtheria, tetanus and botulinus toxins that do not pass the blood brain barrier carry a negative charge at the pH of the blood. Of the two toxins that pass the blood brain barrier, lamb dysentery toxin is neutral and cobra toxin carries a positive charge at the pH of

the blood. The experiments suggested that the electrical charge of toxins has a bearing on the problem of the incubation period. The two toxins that are either neutral or carry a positive charge have no incubation period. The importance of these results for the pathogenesis of infectious diseases is discussed in the case of diphtheria.

Pseudo-Ephedrine in Asthma—Bray and Witts assessed the relative value of ephedrine and pseudo-ephedrine by the diminution in the number of attacks produced by the continuous administration of the drugs and by the relief of the actual paroxysm by the administration of the drug at the onset of the attacks. Twenty children, twelve boys and eight girls, aged from 4 to 9 years, were chosen who had had their asthma for at least two years, had attacks more or less all the year round and had not previously had hospital treatment. These children were divided into four groups of five children and observed during alternate control periods, periods while taking ephedrine regularly and periods while taking pseudo-ephedrine regularly. The dosage employed one-fourth gram (0.016 Gm) morning and evening for a child less than 7 years of age and one-half gram (0.03 Gm) morning and evening for a child more than 7 years of age. The mothers were instructed to give an additional tablet whenever an attack threatened. During the control period all the children had two teaspoonfuls of water just colored with burnt sugar three times a day. No other treatment, antiasthmatic or otherwise, was given. The twenty children during a control period of twelve months had forty-nine attacks, in eighteen months on ephedrine they had seventy-eight attacks and in eighteen months on pseudo ephedrine they had fifty-two attacks. The attacks were most severe in the control periods, less severe while taking ephedrine, and least severe while taking pseudo ephedrine in almost all cases. It was found that in relieving paroxysms ephedrine gives relief in about 85 per cent of adult asthmatic patients and unpleasant reactions in 50 per cent and that pseudo ephedrine gives relief in about 60 per cent of adult asthmatic patients and unpleasant reactions in 20 per cent. The therapeutic efficiency of these drugs is rather closely correlated with their toxicity, but in a few patients pseudo-ephedrine will relieve the asthmatic paroxysms when ephedrine has had to be abandoned on account of its unpleasant side actions.

Lysis of Fibrin by Streptococci—Hadfield and his associates tested the susceptibility to fibrinolysis of 130 samples of human plasma and the fibrinolytic power of thirty strains of streptococci showing β -hemolysis on blood plates, and have confirmed the conclusion of Tillett and Garner, and Tillett, Thomas and Garner that hemolytic streptococci vary in their power to liquefy a normal plasma clot. They fall into three groups with a fair degree of accuracy. In the first, fibrinolysis is rapid and complete; in the second the clot is completely digested in approximately double the time taken by cultures in the first group; in the third, lysis is slow and is incomplete at the end of twenty-four hours. Eleven of the thirty strains of hemolytic streptococci were found to liquefy human fibrin rapidly. The majority of these lytic strains were isolated from cases of severe human infection and, with one exception, their colonies on solid mediums were 'rough' and virulent to mice. Weakly fibrinolytic strains showed glossy colonies and were less virulent. The liquefaction of human plasma clot by hemolytic streptococci is not related to the fibrin content. Total resistance to fibrinolysis appears to be a specific immunity response to infection by hemolytic streptococci. The plasma clot of children suffering from acute and subacute rheumatism was frequently found to show total resistance to fibrinolysis.

Thrombopenic Hemorrhagic Purpura—Loewy presents a case of Werlhof's disease and two milder cases of thrombopenic

purpura that were due to prolonged administration of the new hypnotic sedormid (allylisopropyl-acetyl-urea) to hypersensitive patients. In the first case, after recovery, thrombopenic purpura was produced at will by giving from a half to one 4 grain (0.25 Gm) tablet of the drug. The elucidation of these cases was by no means simple, as the drug had been considered harmless and the patients had taken the drug repeatedly for some time without apparent ill results. Severe loss of blood platelets and consequent hemorrhagic diathesis have been caused by the usual doses of the drug. Repeated administration of a drug may lead to an illness due to sensitization, or show an allergotoxic effect. This condition is unlike the typical purely allergic disorders and distinctive according to the chemical nature of the drug. The modern hypnotics and sedatives are valuable but are never entirely harmless. Careful supervision is required, especially with drugs of recent introduction and with hypersensitive patients whose digestive tracts are irritable. Cases of essential thrombopenic purpura may be traced to drugs that have been taken for some time with no evidence of ill effects (arsphenamine, sedormid). If the patient receives a blood transfusion, time will be gained for closer investigation and an operation may be avoided.

Studies in the Composition of the Gastric Juice Part II G V Rudd —p 455

*Observations on Hemochromatosis K Maddox and E Beatrix Durie —p 463

Observations on Hemochromatosis—Maddox and Durie describe four cases of hemochromatosis. Since cirrhosis and pigmentation of the liver are the only features common to all cases, they are of the opinion that hemochromatosis is merely a syndrome of liver cirrhosis in general and not a separate disease entity. It represents an advanced stage of 'pigment cirrhosis'. The disturbance of carbohydrate metabolism is partly pancreatic but mainly hepatic, wherein the extent of iron deposition is a fairly accurate index of the degree of interference with glycogenolysis and glycogenesis, possibly owing to deficient formation of insulin kinase. In the few patients benefited by insulin, damage or dysfunction of the pancreatic islets is assumed to be present. Prolonged epigastric pain is an evil prognostic sign. The authors believe that further work in this field can be applied best in the direction of ascertaining the character of the iron and copper balance over an adequate period and by close biochemical investigation of the terminal coma of the disease, which clinically has points of difference from both true diabetic coma and cholemia together with further research on the glycogen and pigment metabolism in other types of liver cirrhosis.

Carbohydrate Tolerance in Diabetes Following Administration of Dextrose and Insulin—Ellis used dextrose and insulin hourly without other food over periods of days in the treatment of a number of cases of advanced diabetes. Given in this way, large amounts of dextrose 600 Gm daily, are well tolerated in advanced diabetes the requirement of insulin being no greater than that necessary on an ordinary restricted diabetic diet. During and following such administrations of dextrose marked temporary improvement in carbohydrate tolerance with great reduction in the amount of insulin required sometimes occurs. In the most marked instance the reduction of insulin was from 192 units daily before the administration of dextrose to 9 units daily on the twenty-first day after administration of dextrose the diet being unchanged. The explanation of this improvement is not known. The possible bearing of these observations on the theories of the pathogenesis of diabetes is discussed.

Icterus Gravis Neonatorum—According to Hawksley and Lightwood, icterus gravis neonatorum can no longer be regarded as an isolated disease. Evidence has accumulated that brings it into relation with fetal dropsy and hemolytic anemia of the new-born. The diagnosis cannot be reserved for the familial cases, which form only a proportion of the total. Its conception as a disease of the liver must be widened. The blood changes consist in a rapidly developing anemia, almost unanimously agreed to be hemolytic. There is a brisk response by the hematopoietic tissues, which are intensely stimulated, and, with the outpouring of nucleated red cells, an embryonic blood picture occurs. The pathologic observations consist in persistence of extramedullary hematopoiesis, and the cell pattern of the bone marrow shows immaturity and signs of regenerative activity. Cell degenerations and necroses occur in both the liver and the brain in certain cases. Among the known sequelae in nonfatal cases are anemia and nervous manifestations. Evidence is given suggesting that some cases of idiopathic juvenile cirrhosis and splenic anemia may take their origin in icterus gravis and that the etiologic background of hepatolenticular degeneration may be related to kernicterus. The authors discuss the treatment of icterus gravis and emphasize the value of repeated blood transfusions. The cause of fetal erythroblastosis, including icterus gravis, remains unknown, but they conclude that the evidence suggests that it is a primary hemolytic process rather than a primary disturbance of blood formation. There is insufficient evidence definitely to incriminate a toxin (or toxins), though this explanation is suggested by certain of the facts. The possibility of a hereditary factor in the production of the disease has never been adequately investigated.

Peripheral Circulation in Lobar Pneumonia—Perry studied the reactions of the small vessels of the skin in twenty-six cases of lobar pneumonia. An impaired efficiency in the contractility of the capillaries at the height of the disease was demonstrated. The recovery of the capillaries is slow and not immediately affected by the crisis. Part, at least, of the circulatory failure encountered in lobar pneumonia is due to the impaired efficiency of the small blood vessels. The blood pressure is raised rather than lowered during the acute phase of the disease. Experimental and clinical observations suggest that in the majority of cases of lobar pneumonia both the vasomotor center and the myocardium suffer little damage and yet the patient dies of circulatory failure. The author's studies support the suggestion of Ritchie that the circulatory failure in lobar pneumonia is really a failure of the circulation at the periphery. If this theory is accepted it has obvious bearings on the treatment to be adopted, since efforts to stimulate and improve the tone of the minute blood vessels are more likely to benefit the patient than attempts to increase the efficiency of the heart itself. The slow recovery of normal efficiency in contractility of the capillaries observed in this study indicates the need for prolonged and careful convalescence in lobar pneumonia.

*Cerebral Hemorrhage with Recurrent Transient Hemiplegia and Jacksonian Fits Case O K Williamson and F W Simson —p 249

How to Conduct a Baby Show A M Geddes —p 251

Cerebral Hemorrhage, Transient Hemiplegia and Jacksonian Fits—Williamson and Simson report a case of cerebral hemorrhage in which a temporary right hemiplegia occurred, and later on Jacksonian fits, with a temporary right hemiparesis, evidently resulting from a lesion in the same region of the brain. The condition of right hemiplegia the signs of which disappeared completely, seemed to be most reasonably explained by a spasm of the muscular coat of the arterial branches supplying the part of the brain involved, and the Jacksonian fits were accounted for by the same hypothesis. The patient was accordingly treated with increasing doses of erythrol tetranitrate in tablet form. The pyramidal motor fibers passing from the precentral area in front of the fissure of Rolando were uninvolved by the former hemorrhage except in regard to a few of those concerned in the voluntary movements of the arm. The most obvious explanation of the

hemiplegia would appear to be that this was due partly to edema round the effused blood involving the motor fibers, and partly to the pressure of the effused blood itself, the paralysis thus being caused. The extent of the paralytic and other signs in the early stage of a cerebral hemorrhage is greater than that which is noticeable later on when the edema has passed away. Of special interest is the fact that the actual hemorrhage practically left uninvolved the motor fibers, so that all the paralytic signs were due to the associated edema and pressure of the effused blood and that these signs completely disappeared coincidentally with the absorption of the edematous fluid. Such a clinical picture with corresponding postmortem observations must be uncommon. The Jacksonian fits, which started in the area of the right thumb, are explained by the involvement of some of the arm fibers by the hemorrhage. An alternative explanation is that there had been a condition of spasm affecting the arterial branches supplying the area, which was the seat of the old hemorrhage and which also extended to the part corresponding to the transient recurrent paralysis, that later on rupture corresponding to the old hemorrhage took place in some of the vessels, but that the spasm passed off in those vessels supplying the localized area whose temporary loss of function caused the paralysis. It should be borne in mind that the conditions which are believed to favor spasm of cerebral arteries are precisely those which render likely the occurrence of intracranial hemorrhage. Jacksonian fits are rare phenomena as a result of cerebral hemorrhage, though they may occur in any organic lesion of the brain or its membranes or, indeed, in uremia or dementia paralytica. The fact that there was a nutmeg liver suggests that the edema may have been partly cardiac in origin.

Nerve-Center Poisoning by Morphine.—Hayashi produced either acute or chronic poisoning with morphine in thirteen adult rabbits. He observed the pathologic and histologic changes in their nerve center system. In cases of acute morphinism there was no marked change in the pia mater of the brain and the spinal cord. In cases of chronic morphinism the cerebral pia mater of some of the rabbits became slightly thicker. Acute morphinism caused no marked change in the cells of the walls of blood vessels. Chronic morphinism caused the walls of blood vessels to become slightly thicker and some of the cells in the walls to shrivel and cohere to some slight degree. In both the acute and the chronic type of morphinism, hyperemia and hemorrhage were produced. The change in nerve cells poisoned by morphine is retrograde. In cases of acute morphinism, Nissl's acute cell disease occurs. Chronic morphinism causes serious and chronic cell disease. The lipid content of the nerve cell increases and neurofibrils are altered. The neuroglia is not changed to a marked degree by acute morphinism. In chronic morphinism, both progressive and retrograde changes are noted, with a small increase in the fibroglia. In acute morphinism, the medullary sheath is not changed as a rule. Chronic morphinism causes damage of the medullary sheaths of the telencephalic pallium, spinal cord and spinal root nerves. According to tests made by Marchi's method, granulation is increased slightly. The quantity of lipid is increased as a rule in cases of chronic morphinism and is not altered in cases of acute morphinism. An increase of lipid was observed in the walls of blood vessels, nerve cells and cells of neuroglia. The increase was especially marked in the conical cells of the horn of Ammon, the telencephalic pallium and the globus pallidum.

 *Clinical Diagnosis of Tracheobronchial Adenopathies. Some Hitherto Unpublished Symptoms. K. Rachid—p. 213
 Acute Leukemia with Grave Ulceronecrotic Angina in Child. C. Kizoulis—p. 217

Clinical Diagnosis of Tracheobronchial Adenopathies.—Rachid states that tracheobronchial adenopathies in the course of their development are more easily detected by clinical than by roentgen examination. He maintains that percussion of the anterior aspect of the thorax, especially of the sternoclavicular angles on both sides, is more advantageous than that of the posterior aspect, at which the interscapular region is the site of predilection. The anterior and superior aspects of the thorax in infants possess an almost uniform thickness as far as the axillary line, while posteriorly the uniform thickness of the wall exists only in a small area between the border of the scapula and the prevertebral muscles. Thus, in a child lying supine with arms extended, percussion may reveal an equal resonance in the first intercostal spaces from one axillary line to the other (negative adenopathy) or a diminished resonance close to the axillary line (glandular mass by itself or associated with the apices). This sign points to the existence of relative hypertrophied nodes of the anterior wall. Adenopathy of the thoracic cavity consists of newly formed masses; these tumefactions are found during the stage of phlegmasia. The symptom of respiratory silence is produced by compression of a large bronchus. This arises from the flattening of the bronchus, as a result of the flexibility of the cartilage in the child, by a nearby glandular mass, or is due to a tumor within the bronchus cutting off the air. The symptom often consists of absence of respiratory sounds of the left anterior, posterior or lateral pulmonary lobe in which percussion does not denote any local dullness. When the mass is in the inflammatory stage, auscultation reveals a pleural rub and suppressed breathing. These signs are localized over a large area: the right or left subclavicular space anteriorly, the first and second intercostal and interscapular spaces close to the median line posteriorly. Auscultation is best performed after a slight cough. The development of these signs takes place during the inflammatory stage and disappears after its regression. The author explains the mechanism of the pleural and pulmonary exudation as a vasodilatation and passive hyperemia produced in these tissues by hyperplastic adenitis, the vascularization of which is intensified by inflammation.

Virulence of Tubercle Bacillus.—To answer the question whether in the spontaneously disappearing tuberculous exudates the fluid becomes bactericidal outside the organism, Nedelkovitch made exploratory punctures on eleven patients. Each specimen was left for a longer or shorter period either at the laboratory temperature or that of the incubator. The material was injected into guinea-pigs. In all instances positive evidence of live and virulent tubercle bacilli was obtained. He concludes that tubercle bacilli are not dead in disappearing exudates and that convalescence and cure result in spite of the presence of living virulent organisms. Recovery depends, therefore, not on the presence of bacilli in the exudate but on the relation between the bacilli and the cells (and probably other elements) in the pleural lesions themselves. In the purulent pleuritis of pneumothorax which disappear spontaneously and in which the recovery lasts a long time, the specimens taken toward the end lose their virulence much more rapidly than those obtained at the early appearance of the exudate. Furthermore, it was apparent that the bacilli in the exudates were just as resistant to the bactericidal properties of the exudate outside the body as inside. These bacilli, however, become sensitive to this bactericidal

action of the exudate after passage through culture mediums. When recovery begins, the organism becomes insensible to the poisonous effect of the bacteria, but the bacilli also are resistant to the bactericidal action of the tissues. In making repairs the organism clears out the bacilli in the same way as it does cellular debris or foreign bodies. Thus the enormous number of bacilli disappear, although some may persist and can produce new lesions in case of returned lowered resistance on the part of the host.

Death from Drowning—Werner shows that the drowning of the person who does not swim differs from the drowning of swimmers, the latter occurrence being designated as sinking. Whereas in the persons who do not swim death is caused by suffocation because of the inability to keep above water and to breathe the cause of the sinking of swimmers lies in the body itself. The sinking of a swimmer generally takes place without a struggle as the result of partial or total loss of consciousness. The author states that laymen generally ascribe the sinking of a swimmer to loss of movement, to "spasm" but he points out that there are several other possibilities. Ulrich advanced the theory that the main cause of the sinking of swimmers is digestion hyperemia, and the author decided to investigate this theory in postmortem examinations on fifty drowned persons of whom twenty-seven had died while swimming. In about 70 per cent of these, digestion hyperemia, occasionally combined with other factors, was the cause of death. 10 per cent had severe cardiac and vascular disturbances, and it may be assumed that they sank because of sudden death in the water, and 20 per cent had no digestive hyperemia but had mild cardiovascular disturbances or other anomalies. In the latter group, various causes may have caused death. In thirty-two cases the petrous bones were examined in order to determine whether the sinking was the result of otogenous factors. The author believes that otogenous drowning is comparatively rare. He thinks that the possibility of this mode of death can be conceded in only one of the thirty-two cases examined for this cause. Approximately 90 per cent of the swimmers who died sinking had slight or no hemorrhages in the middle ear. Such changes were most frequent in the nonswimmers who drowned. The author gives the following warnings to bathing or swimming persons. 1 It is dangerous to bathe or swim while the stomach is filled, for digestion hyperemia is one of the main causes of death. 2 Weak and hypersensitive persons, and particularly those with heart disease, must be especially cautious. 3 Patients with disease of the middle ear should be aware of the fact that the entrance of cold water into the ear irritates the labyrinth, causes vertigo and may lead to drowning.

The Ear and Death from Drowning—Schmid states that the managements of swimming pools warn persons with defective tympanic membranes against diving. The author relates the histories of three persons in whom a rupture of the tympanic membrane occurred while diving. In discussing these cases he shows that not only perforated tympanic membranes deserve attention but abnormally thin membranes and those with atrophic scars likewise present a grave danger. For this reason the examining otologist should search for perforations and should examine the mobility of even apparently normal tympanic membranes by means of Siegle's speculum. Moreover even in the case of an apparently normal tympanic membrane the diver should be advised to protect the ears against the force of the water.

Paralysis of Hypoglossal Nerve in Sore Throat—Ulrich reviews twelve cases in which unilateral paralysis of the tongue developed in acute pharyngeal disturbances. The causal disorder was generally a severe sore throat with abscess formation or extensive swelling of the cervical glands. The hypoglossal paralysis was always unilateral and developed on the more severely affected side. The direct overlapping of an inflammatory process on the nerve seems to be the main factor in the development of the hypoglossal paralysis. The author also describes four cases of his own observation. In two instances microscopic examination revealed that the lesion of the hypoglossal nerve was due to periphlebitis of the jugular vein and of the posterior facial vein, respectively. The surgical observations in the third case and the clinical course of the fourth indicate the same mode of impairment.

Treatment of Laryngeal Stenoses—The therapeutic method suggested by von Gunten for the treatment of laryngeal stenoses employs an individually fitted retention tube. It avoids the obstacles developing as a result of the irritation of the mucosa and also exerts a mild and uniform pressure on the stenosis. In order to fit the tube correctly, an imprint is made of the larynx by means of gutta-percha. A cast is made of this imprint and then a silver tube is formed. Illustrations of the tube in various positions show that the external orifice can be closed by a valve. One of the two patients for whom the author employed this method had undergone a high, the other a low, tracheotomy in the treatment of diphtheria. The tube caused no irritation, it excluded the danger of asphyxia and in a comparatively short time respiration was possible again by the natural channel. The removal of the tube proved impossible because the stenosis persisted, but the patients were not annoyed by it and were able to lead a normal life. The author does not intend to discontinue this treatment. He thinks that, if the action of the tube has widened the stenosis sufficiently, it will be possible to withdraw the tube and to close the tracheostomy.

Treatment of Cerebral Hemorrhage—Colella and Pizzillo studied cases presenting encephalic traumas, hemorrhages and cerebral embolisms at different pathologic stages. They found that the effects of cerebral hemorrhage may be corrected to a marked degree and sometimes totally by intramuscular injections of the blood of the patient. This auto-hemotherapy consists in taking from 25 to 30 cc of blood from a vein of the arm or of the foot and reinjecting it immediately into the gluteal region of the healthy side. Before puncturing the vein, it is advisable to pour several cubic centimeters of a 25 per cent solution of sodium citrate into the syringe in order to prevent premature coagulation of the blood. These injections are hemostatic and are an aid to the treatment of cerebral hemorrhage and its effects in all cases, irrespective of the origin or nature of the hemorrhage, the age of the patient and the time of attack. Cures have been observed in the most acute cases and in severe traumatisms to the head in which the symptoms are due to a genuine cerebral hemorrhage. The results are better and more rapid than those of surgical intervention. Autohemotherapy is beneficial in the treatment of cerebral hemorrhage before, during and after a stroke. It may be administered as a prophylactic in cases of arterial hypertension with hereditary predisposing conditions, vertigo, weakness of the limbs and tremors of the extremities are frequent premonitory signs of stroke in arteriosclerotic patients, and their results are avoided or immediately corrected following the injection which abruptly lowers the intracranial vascular pressure. Injections of blood are valuable in making a differential diagnosis between cerebral hemorrhage and cerebral softening. Although cerebral hemorrhage is more frequent than softening and the symptoms are often the same they may be distinguished by the curative action which is strong in the foci

of cerebral hemorrhage and weak in those of cerebral softening. The authors are at a loss to explain the mechanism by which the intravenous injections act so beneficially on the foci of the cerebral hemorrhage.

Hormone of Posterior Hypophysis in Pregnancy—

Rupp and Bickenbach report the reaction of the pregnant organism under the influence of the hormone of the posterior hypophysis. These investigations were made in view of the new theory of the hypophyseal origin of eclampsia. They found that the manner of water elimination under the influence of the hormone of the posterior hypophysis is not changed by the existence of a pregnancy. Observations on the chloride elimination revealed that a sudden action of the hormone of the posterior hypophysis may lead during pregnancy to a temporary increase in the percental quantities of chloride in the urine, but that in case of a continuous water retention under the influence of the hormone of the posterior hypophysis there develops also a chloride retention. The action of the hormone of the posterior hypophysis seems to be masked by the change that takes place in the chloride metabolism during pregnancy. There is no contradiction between the chloride retention during pregnancy and the assumption of an excessive hormone action of the posterior hypophysis in pregnant women.

Hepatic Functions in Hyperemesis Gravidarum—Schmidt and Herold tested the hepatic functions of twenty-one women with hyperemesis. The outcome of the galactose test indicated a disturbance in the carbohydrate metabolism, namely, a reduced assimilation capacity. The xanthoproteic reaction revealed a disturbance in the intermediate protein metabolism characterized by the presence of aromatic amino acids. The course of the direct, and the quantitative values of the indirect, bilirubin determination disclosed an impairment of the hepatobiliary pigment metabolism. Moreover, it seems probable that the increased porphyrin elimination in the urine was the result of a disordered hepatic function. Although the functional tests of the liver were not all simultaneously positive, they frequently ran parallel with the severity of the clinical aspects or even preceded them. The authors think that these tests are valuable in the estimation of the individual case and aid in deciding the interruption of the pregnancy.

Hemogram During Delivery—Koller and Bollag studied in 410 cases the changes in the blood picture during spontaneous and pathologic births. They found that an increase in the staff cells during birth indicates that the woman is in great danger of puerperal infection. In cases in which the staff cells increased to more than 25 per cent, puerperal infections developed in more than half of those in whom a vaginal operation was performed and in 80 per cent of those who had to undergo a cesarean section. A temperature higher than 38 C (100.4 F) during delivery has not the same value in forecasting puerperal infections as has the increase in the staff cells, however, together with the changes in the hemogram and other clinical signs, the temperature nevertheless should be given consideration. The author considers the study of the hemogram, particularly the staff count, indispensable in estimating the efficacy of a new method of surgical delivery. He emphasizes that this material proved again, just as former studies had done, that in deliveries terminated by vaginal operations the infection mortality was much lower than in those completed by abdominal interventions. These differences are especially noticeable in the groups with greatly increased staff count.

 New Case of Pellagra H Boas—p 84
 *Scurvy with Pellagroid Cutaneous Manifestations F Sagher—p 86
 Sensitivity and Desensitization in Eczema of Nurslings H Burchard—p 92

Experimental Transmission of Mycosis Fungoides—

Zurhelle points out that in the positive transmissions of mycosis fungoides, which have been reported in the literature thus far, the bacteriologic examination has been neglected. Following a short review of the literature he describes his own transmission experiments on ninety-eight animals (eighty-nine guinea-pigs and nine rabbits). They were inoculated with material from two patients with mycosis fungoides, whose clinical histories the author reports. The difficulties of the bacteriologic investigations and the diversity of their results are revealed especially in the fourth series of tests. In this series one guinea-pig showed considerable changes in the spleen, the bacteriologic examination of these changes gave negative results, while the bacteriologic tests were positive in the guinea pig inoculated with this material. In summarizing his observations the author states that the changes that can be induced in animals by inoculation with pure cultures of paratyphoid B bacillus or of Bacillus pseudotuberculosis rodentium are observable also in the experimental studies on mycosis fungoides.

Scurvy with Pellagroid Cutaneous Manifestations—

Sagher describes a case of scurvy in which, in addition to a hemorrhagic follicular keratosis, cutaneous symptoms were present like those that have been described as pellagroid. Vitamin therapy counteracted the scurvy as well as the pellagroid cutaneous manifestations within a comparatively short time. The author assumes the simultaneous existence of two different manifestations of vitamin deficiency.

- Action of Sauerbruch-Herrmannsdorfer Diet S Bommer—p 735
 *Prevention of Postoperative Thrombosis and Embolism W König—p 739
 *Specific Prophylaxis and Treatment of Whooping Cough Edith Krüger—p 741
 Serology and Specific Therapy of Whooping Cough M Gundel—p 744

Prevention of Postoperative Thrombosis—The procedure recommended by König for the prevention of postoperative thrombosis and embolism consists in the oral administration of twenty drops of synephrin tartrate three times a day for seven days or, if this is impossible, in three daily hypodermic injections of 1 cc of synephrin tartrate and in the inhalation of several breaths of concentrated carbon dioxide every hour for from four to six days. Comparative observations on 4,500 cases revealed that this method gives highly satisfactory results. When the entire surgical material was considered, it was found that under the influence of this treatment the incidence of postoperative thrombosis and embolism was reduced from 38 per cent to 1.04 per cent. A consideration of the serious interventions showed an even more striking effect, for here the reduction was from 62 per cent to 0.95 per cent. The pulmonary complications, such as pneumonia and bronchitis, were reduced from 94 to 34 per cent.

Prophylaxis and Treatment of Whooping Cough—

Krüger describes her experiences with a new and improved vaccine prepared by H Langer. This vaccine contains fifty-eight strains from various epidemics. Especial care was taken that the bacteria had retained their requirements for large amounts of blood in the culture mediums, so that in spite of prolonged cultivation they behaved like fresh strains. The endotoxin was removed as far as possible, so that the vaccine consisted of toxin-free bacterial fractions. In this connection the author calls attention to the fact that in the blood of patients with whooping cough the antagonism of toxin and antitoxin is not the decisive factor, as is the case in diphtheria, but that lysins are formed against the whooping cough bacillus. Thus it is the bacterial body rather than the endotoxin that is the stimulus for the antibody formation. The author thinks that the absence of the endotoxin accounts for the fact that the vaccine is so well tolerated. In the course of over 200

injections, she never observed unfavorable local reactions or disturbances in the general condition. She ascribes to the action of the protein the slight fever that developed in some cases. She employed this vaccine in forty-two children. It was administered by intramuscular injections. Four injections were given in the course of eight days. The first dose contained five, the second ten, the third fifteen and the fourth twenty billions of organisms. Good results were obtained during the first and second stages of the whooping cough. In the children in whom the vaccine was given later, failures were frequent. Ten children who were exposed to whooping cough were given prophylactic treatment with the vaccine, and seven of them were protected. The author recommends the prophylactic use particularly for infants, because in this group the mortality of whooping cough is rather high.

Treatment of Thoracic Empyema with Suction Irrigation Drainage M Tiegel —p 757

Influence of Iodine on the Thyroid—Irsigler states that the influence of iodine on the thyroid is due to its effect on the epithelial cells of the follicles. The action in accordance with the general biologic law, is first that of stimulation and later that of paralysis and destruction of the cell and its replacement by regenerative processes. The function of the follicular epithelium expresses itself in two directions. 1 The building up of the specific thyroid secretion, which is either stored in the lumen of the follicle or is directly absorbed from the cell into the blood circulation and is recognizable at the periphery by its biologic effect. 2 The resorption of the stored up secretion after the latter was converted into an absorbable form, to supply increased demand by the organism. The morphologic expression of these processes are to be found in the consistency of the stored up secretion designated by the terms "thick" and "thin" and further by histologic reactions to fixation and coloration as shown in the phenomenon of true vacuolization. The enlargement of the inner surfaces of the thyroid under the influence of iodine in the form of nodosities and papillae can be best explained from this point of view. Both functions of the follicular epithelium may be influenced by the iodine, and there is no way of obtaining at will the desired effect in every case. This constitutes the blind principle in the action of iodine and therefore contains a certain element of danger in the iodine treatment of goiter. The histologic effect of iodine in hyperthyroidism of human beings presents a picture of fairly characteristic alterations in the histologic sections. The histologic effect however, is not proportional to the duration of the exhibition of the compound solution of iodine, nor does it always correspond to the clinical effect.

Movements in Cerebrospinal Fluid System Wustmann —p 666

Anemia in Premature Infants—Thoenes shows that medication with iron or liver preparations does not prevent anemia in premature infants and concludes from this that it is not a deficiency disease. He thinks that it is due to the same processes that produce a reduction of the hemoglobin and of the

erythrocytes in full-term infants and occasionally lead here also to a mild anemia. These processes resemble "acclimatization manifestations," that is, they result from the adaptation of the organs to the greater oxygen supply compared to the intra-uterine conditions, for the improved provision with oxygen leads to the disintegration of the elements no longer necessary for oxygen transport. These blood elements decrease because birth terminates the intra-uterine anoxemia that served as a stimulus for their formation. The premature infant must complete the intra-uterine development under conditions to which the developmental stage of its organs are not yet fully adapted. The hematopoietic apparatus particularly, is still adapted to the metabolic processes of the fetus, that is, to a comparatively small oxygen supply, and this anoxemia, which exerts a strong stimulus on the erythropoiesis, is prematurely terminated by a too early delivery. Thus it is understandable why the erythropoietic organs of the premature infants under changed conditions fail to come up to the requirements to which they are equal only under the stimulus of the intra-uterine anoxemia. The author concludes that the physiologic anemia of premature infants is the result of a relative insufficiency of the hematopoiesis which is hardly at all amenable to treatment.

Endemic with Pneumococcus of Type I—Joppich reports an influenza-like endemic, which occurred in a children's home. A boy, aged 2 developed double pneumonia, suppurating pleurisy and suppurating meningitis and died. The cerebrospinal fluid contained pneumococci of type I and the same organism was found in the lungs and in the pleural pus. Histologic examination of the lungs revealed a localized pneumonia. Several days later three other children, aged 9, 11 and 13 developed lobar pneumonia. Type I pneumococcus was also found in these children. An inspection of the home at this time revealed that of twenty-nine children twenty-one were ill, as were also several adults. The respiratory tract was affected (pharyngitis, tracheitis, bronchitis). Some of the patients were feverish for several days, while in others the general condition was only slightly impaired. There was no connection between the severity of the disturbance and the ages of the patients. Nasopharyngeal smears were taken from thirty persons and twenty-three smears yielded pneumococci, fifteen of them belonging to type I. Several observations made in the course of this endemic are significant for the pneumococcus problem. Perhaps the most important observation is that the type I pneumococcus does not always lead to lobar pneumonia but that in most instances it causes only mild catarrhs or a localized pneumonia (first case mentioned). The author thinks that this explains why lobar pneumonia occurs only rarely as an epidemic. He assumes that the resistance plays a part.

Inhibition of Agglutination in Retroplacental Blood—In tests on the intervillous blood and the amniotic fluid of pregnancies with foreign blood groups, Saker was able to determine that the decrease in the agglutinin titer of the retroplacental blood was the result of a specific inhibition by fetal antigen. However, there is no transition of fetal agglutinogens through the placenta into the retroplacental blood. The author thinks that the decrease in the specific agglutinin is due to an admixture of amniotic fluid, which cannot be avoided at the moment of the expulsion of the placenta.

New Indication for Use of Hormone of Anterior Hypophysis H Kopf —p 613
Consistency of Mud and Moor Packs and Baths F Freund —p 613

Occupational Diseases of Dentists—Löwy classifies the occupational diseases of dentists into three groups (1) those caused by unsuitable posture during work (2) infectious diseases and (3) poisonings. Whether the frequent neurasthenia is a disease sui generis he is unable to decide, but he thinks that it

may be due to prolonged confinement in closed rooms. In discussing the disorders caused by unsuitable posture, he mentions first the thoracic changes, which in turn may lead to cardiac and circulatory disorders. Prolonged standing may lead to the development of flatfoot and varicose veins. Removal of tartar from the teeth involves the danger of corneal injuries, and handling of plaster of paris may lead to the formation of rhagades. The infectious diseases that threaten the dentist are particularly those of the upper respiratory tract, such as diphtheria, catarrhs, influenza, tonsillitis, mersles, scarlet fever and tuberculosis. There is also a certain danger of an extragenital syphilitic infection. The frequent use of the roentgen apparatus likewise involves dangers. The use of certain chemicals may lead to eczema. One of the greatest dangers is chronic poisoning by mercury. The author thinks that nervousness, which occurs rather frequently in dentists, is often the result of chronic poisoning. Dentistry as a profession is inadvisable unless the person has a normal nervous system and an intact respiratory apparatus, the nasal breathing, particularly, should be free. There should be no predisposition to curvature of the spine or to the development of flatfoot and varicose veins.

Hormone Treatment of Loss of Hair—Hocker points out that the pathogenesis of alopecia areata is not completely understood. Some assume a parasitic, others a neurogenous and still others ancretory origin. The author recommends caution in the therapeutic evaluation of hormone therapy in alopecia. The therapeutic value of a hormone preparation must be proved in severe cases and its effect must be lasting. He gives the history of a woman who at the age of 19 first observed small hairless areas on the occiput. These areas increased in size and, in spite of quartz lamp irradiations, embrocations with croton oil and other preparations, she finally lost all her hair. The woman had always had menstrual disturbances, her menarche was late and after that she was amenorrheal for a time. She also exhibited symptoms indicating a hyperfunction of the anterior lobe of the hypophysis. Under the influence of oral administration of a follicular hormone preparation, a downy, colorless hair growth appeared and the menstrual flow was normalized. When after three months growth of the hair ceased, the doses of hormone were increased not only were larger oral doses given (450 mouse units daily) but, in addition to this, 200 mouse units was administered by subcutaneous injection. Gradually the hair growth increased again, but after a while the hormone therapy was discontinued and three months later the hair began to fall out again. Renewed daily hormone injections (1,000 mouse units) increased the hair growth again. The observation covered three years but the improvement never became a complete cure. The author believes that hormone therapy alone is not sufficient to reestablish normal hair growth.

*First Results of Treatment of Schizophrenia with Placental Blood J. S. Galant—p. 752
*Removal of Tattooing by Method Applicable by Practitioner H. in der Stroth—p. 753

Treatment of Gonorrhea in the Female—In evaluating the therapy Johnen cites the results obtained by different workers with vaccines of killed or of living organisms and with mixed vaccine. While some report favorable results, others experienced serious complications, and for this reason the author dispensed with the vaccine therapy. Of the non-specific therapeutic methods he discusses the active local therapy, fever therapy and conservative therapy. The conservative treatment consists in strict rest in bed, the application of ice bags, poultices, heat in the form of hot pads or diathermy and occasional vaginal irrigations. Thus it is limited to general measures and dispenses with local therapy. At the author's clinic, the patients with signs of a new ascending infection or an acute pelveoperitonitis with high fever were treated conservatively, while those without fever were subjected to local therapy. A comparison of the results reveals that the local treatment is not superior to the conservative

treatment and has the disadvantage that ascending processes are more frequent. The author does not advocate the general employment of conservative treatment in gonorrhea because he realizes that two factors were essential in its efficacy (1) strict clinical supervision and (2) all the patients had high fever, so that they received an involuntary fever therapy. The author states that the results of the local treatment were considerably improved with the introduction of a new acridine preparation that contains arsenic in an organic form. From 1 to 4 cc of a 2 per cent solution of the preparation is introduced by slow injection into the urethra and the cervix. The treatment usually requires eight injections. In cases of rectal gonorrhea from 2 to 4 cc of a 0.25 per cent solution is administered. Of twenty-one women with chronic gonorrhea, eighteen recovered as a result of this treatment. Moreover, this method reduces the duration of the treatment considerably.

Placental Blood in Treatment of Schizophrenia—Galant treated thirty-seven patients presenting various forms of schizophrenia, such as the katatonic, hypochondriac, paranoid and hebephrenic types, with subcutaneous injections of placental blood. The blood is obtained from the placental end after cutting of the umbilical cord. The injections are made either daily or after intervals of from two to three days. During the first treatment 4 cc is given, and during the subsequent injections the amount is increased by 2 cc until a total of 10 cc has been reached. In all, fifteen injections are given. The blood must be fresh, that is, it must be injected on the day of withdrawal, otherwise undesirable complications are likely (increase in temperature, headaches, vomiting). This hemoplacental therapy effects a considerable improvement in the general condition of most schizophrenic patients in that their weight increases. The psychotic condition is influenced in that the stuporous patients become livelier and the agitated ones become calmer. The stuporous patients are improved to such an extent that they can be subjected to work therapy, which was previously impossible. In discussing the action mechanism of the hemoplacental treatment, the author points out that it involves two factors, a biologic action and a psychotherapeutic action. The first of these in turn involves two factors, the protein shock therapy and the hormone action, for the placental blood doubtlessly contains large amounts of hormones. The psychotherapeutic effect is due to emotional shock and to suggestion. At the beginning of the treatment the hemotherapy may lead to hallucinations, but these usually pass off rapidly. If the first series of injections produces no definite results, a second series may be given after six or eight months.

Simple Method for Removing Tattooing—Since none of the commonly used methods for the removal of tattooing proved entirely satisfactory, in der Stroth followed Bruck's suggestion and employed an ointment representing a modification of the pyrogallic ointment that Unna employed in the treatment of lupus. The ointment is freshly prepared from 7 Gm each of pyrogallic acid, salicylic acid and resorcinol, 5 Gm each of glycerin and diluted alcohol and 1 Gm. of tragacanth. The area around the tattooed pattern is protected by covering it thickly with zinc ointment. A piece of impregnated gauze, the size of the tattooed area, is covered with the caustic ointment and is applied to the tattoo in such a manner that the margin of the gauze rests on the zinc paste. The entire application is securely fixed by layers of gauze and by adhesive tape. This bandage is removed after twenty-four hours. At this time the epidermis can be removed. A new caustic ointment bandage is applied in the same manner as the first, but this second one is left in place for forty-eight hours. After this time the area has usually become necrotic, and only in exceptional cases does a third application of the caustic ointment become necessary. As a rule, the area can be cleansed with oil after the second application, and then the necrotic tissues gradually slough off, the process being completed in from five to seven days. Following that, granulation sets in and in the course of three or four weeks a smooth scar has taken the place of the tattoo. The author emphasizes that the method is so simple that the general practitioner can readily employ it. The patient should be told that, during the time the caustic ointment is applied, there is considerable pain, but this can be reduced by the use of sedatives. Other undesirable complications, such as intoxications, were never observed.

Methylene Blue-Sugar in Poisoning by Suffocating Gases—Deutsch and Weiss report that a patient, who on account of allergic colitis and hyperthyroid glycosuria was treated with high doses of alkaline substances and with methylene blue (methylthionine chloride) clysters, stated that since he received the alkaline preparation the urine was no longer blue as it had been when he was treated only with methylthionine chloride. This reminded the authors of the sugar test in which methylthionine chloride, by heating with alkaline dextrose solution becomes colorless, but when the mixture cools and is shaken in the air the resorption of oxygen brings back the stain. The oxygen transmission can be repeated by alternating heating and cooling, and this oxidation-reduction process resembles the metabolism of living substances. The authors review studies carried out by Thunberg and by Warburg, and these studies as well as their own observations on the patient with glycosuria induced them to determine whether the reaction of methylthionine chloride with oxygen could be clinically utilized when the oxidation was impaired. In preparing an alkaline methylthionine chloride-sugar solution they found that a solution of from 0.25 to 1 Gm of methylthionine chloride and 10 cc of dextrose in 100 cc was most suitable. They made experiments on animals and also on tissue cultures, and, on the basis of the results obtained in these, they gave intravenous injections of from 20 to 30 cc of the methylthionine chloride-sugar solution in cases of carbon monoxide poisoning and obtained favorable results. Later Geiger's successful use of a 1 per cent solution of methylthionine chloride came to their attention and a review of the literature revealed that Moldenhauer-Brooks had employed methylthionine chloride in poisoning with hydrocyanic acid, and that several other investigators had studied this problem. In discussing the objection made by Haggard and Greenberg that the use of methylthionine chloride could not be supported, the authors point out that the action of methylthionine chloride is not merely the result of the binding of the toxin but also of the stimulation of the oxidation. The addition of sugar increases this action still further, as indicated by Warburg's studies. The authors think that the treatment with methylthionine chloride-sugar solution is indicated in poisoning with the various suffocating gases and suggest its investigation for use in disorders, in which the oxygen carrier is impaired, such as in pernicious anemia, or in which the tissue respiration is threatened by anoxemia.

Histamine Susceptibility—Karady shows that researches of recent years revealed the importance of the antagonism between the "tissue hormone" histamine and the suprarenal hormone epinephrine. This antagonism plays a part also in the regulation of the blood pressure. In former studies histamine was generally administered by subcutaneous injection, but since this method had certain shortcomings, the author resorted to the intravenous injection. He dilutes a 1:1000 histamine preparation at the ratio of 1:100 so that 0.5 cc contains 0.005 mg. The systolic blood pressure is determined before the injection and then every fifteen seconds after the injection. A decrease in blood pressure becomes usually noticeable within fifteen or twenty seconds after the injection, but still within the first minute the decrease is followed by an increase up to the initial level or even beyond it. In some instances the difference between the minimal and maximal pressure is more than 100 mm of mercury. During the increase in pressure tachycardia develops. Two minutes or at the latest three minutes after the injection the blood pressure again decreases to the initial value, and in excitable persons it may maintain a lower level for a longer period. The author made these tests on 200 patients suffering from various disorders. He found that the curves of the pressure fluctuations can be classified in four distinct types. The first type of curve shows a pressure decrease of from 25 to 30 mm of mercury from fifteen

to thirty seconds after the injection. This type was observed in 106 patients presenting various disorders such as gastrointestinal disease, tuberculous changes, bronchial asthma, pernicious anemia, late syphilitic disorders, myxedema, arthritis, various disturbances of the kidney and liver, lead poisoning, poliomyelitis and other disturbances. In the second type of curve a decrease of from 10 to 60 mm of mercury is followed by an increase of from 40 to 120 mm of mercury. This type of curve was noted in fifty-two patients, and the author states that it is often present in persons having hypertension. The third type of curve shows slight fluctuations, a decrease of from 5 to 6 mm of mercury and a return to normal values or slightly above within one minute. This type of curve was found in patients having hyperthyroidism and exophthalmic goiter. The fourth type of curve is characterized by a moderate decrease (10 mm) and then by a moderate increase (10 mm). There are only slight subjective symptoms. This curve was observed in neurasthenic patients, generally with some acute disorder. In the conclusion the author stresses that the peripheral vasodilatation, the pulmonary and hepatic blockage, which play a part in the decrease of the blood pressure following histamine action, are also important in the development of collapse and he assumes that there is a certain similarity between histamine shock and collapse. If further tests will definitely establish this, the method may prove helpful in the detection of a predisposition to collapse and will make its prevention possible.

Cesarean Section and Myoma L Schack—p 1110

Effects of Hormones in Lutein Cysts—Siegmund discusses the explanations that have been given for the development of lutein cysts. It seems that they appear when the hormone equilibrium is disturbed so that there is a pathologic predominance of the gonadotropic hormones, that is, in cases of cystic mole and of chorio epithelioma. They develop from abnormally growing and ripening follicles. As the result of the presence of these lutein cysts, women are kept for weeks in a condition resembling pregnancy. This condition is not due to remnants of chorionic tissue or to increased elimination of hormones of the anterior hypophysis but results from the hormones (folliculin, corpus luteum hormone and gonadotropic principles) contained in the lutein cysts. The assumption that the condition is the result of hormones stored in the cysts is corroborated by the spontaneous disappearance of the cysts and the simultaneous elimination of hormones in the urine, by the rapid cessation of hormone elimination following extirpation of the cysts and by the behavior of the milk glands after extirpation.

Leukocytosis in the New-Born—Ehrenfeld shows that, although the investigators agree on the presence of leukocytosis in the new-born, they disagree on its causes. Some assume an increased activity of the bone marrow, while others maintain that the increase is only apparent and is the result of a loss of fluid. In order to clear up this problem, the author fed tea to one group of newly born infants, beginning with the third hour after delivery. This addition of tea was later continued with every breast meal until the nursing commenced to gain weight. Another group of nurslings was as customary in the author's clinic put to the breast twenty-four hours after delivery and after that every three hours but were given no tea. The number of leukocytes was studied in both groups and the author concludes that the increase in leukocytes in the new-born is not the result of a stimulation of the bone marrow and is not due to influences from the digestive tract but is the manifestation of an anhydremia. The loss of water from the blood plasma may be prevented or at least reduced by feeding with tea. A study of the types of leukocytes reveals that the neutrophils predominate at birth but within a few days this neutrophilia is replaced by the lymphocytosis that is characteristic of the nursing age. F'

percental distribution of the various types of leukocytes was found to be practically the same in the two groups of nurslings. The addition of fluid produces no abnormal conditions and the difference in the leukocyte values corresponds to the concentration of the plasma.

Treatment of Ulcerous Colitis with Blood Transfusions—Hulst and Hartog administered from 400 to 500 cc of citrated blood, comprising from 40 to 50 cc of trisodium citrate at 2.5 per cent, to four patients presenting ulcerous colitis. These transfusions were administered only after dietetic and medical treatment had been tried and found wanting. The authors maintain, however, that even after transfusion the patients should adhere to a strict diet. Transfusions were given three weeks apart. If several transfusions from one donor did not offer appreciable results the blood of another donor was injected. Two patients evinced immediate improvement, while the other two began to improve only after repeated transfusions. A negative result did not occur in any case. The authors found it desirable to repeat the transfusions if the patient did not rapidly respond to treatment. They are at a loss to explain by what mechanism the favorable effect is procured.

*Roentgenologic Characteristics of Echinococcus Disease in Bones G. Claessen—p. 178

Echinococcus Disease in Bones—Two new cases of echinococcus bone cyst formation and two previously reported cases are described by Claessen. Echinococcus disease of bones constitutes from 1 to 2 per cent of all cases of echinococcus parasitism. It is most frequently localized in the pelvis, but hardly any part of the skeletal system appears to be totally exempt. In one of the cases reported the hum and head of the femur were involved, in another the sacrum, in one the diaphysis of the femur and in one the fibula. The infiltration is usually not sharply limited but seems to have some preference for spongy bone. The differential diagnosis from tuberculosis, osteosarcoma and fibrous cystic osteitis is often difficult, but the absence of regional bone atrophy and of periosteal reaction in echinococcus disease may be of important diagnostic significance. The limits of the echinococcus extension can rarely be determined with certainty from the roentgenograms.

- *Disseminated Encephalomyelitis (Redlich) and Infectious Funicular Encephalomyelitis C. C. J. Munch-Petersen—p. 137

Disseminated Encephalomyelitis (Redlich) and Infectious Funicular Encephalomyelitis—Munch-Petersen seeks to define more closely a certain clinical form of infection of the central nervous system, assuming that funicular spinal disease is due to a constitutional factor. It seems to him probable that with the increase in neuro-infections in recent years some of these will present a 'funicular' picture. He reports twenty-seven cases, mainly chronic, of a possible neuro-infectious kind, with a clinical picture of more or less marked funicular character, for which the term myelitis or infectious funicular

encephalomyelitis is suggested. He calls attention to the lack of symptoms pathognomonic of multiple sclerosis in the cases regarded as funicular encephalomyelitis. A single etiologic factor is thought probable for multiple sclerosis, but for encephalomyelitis the possibility of several known or unknown kinds of virus must be considered. Clinically, and presumably also anatomopathologically, transition forms between multiple sclerosis and infectious encephalomyelitis are likely.

- *Attempt at Treatment of Pernicious Anemia with Yeast or Yeast Preparations Incubated with Normal Gastric Juice H. C. A. Lassen and H. K. Lassen—p. 369
Nephrolithiasis—Generalized Osteitis Fibrosa—Hyperparathyroidism H. Strindgaard—p. 383

Treatment of Pernicious Anemia with Yeast Incubated with Normal Gastric Juice—The Lassens treated seven patients with pernicious anemia by this method. Through experiments in animals the various yeast preparations were titrated with regard to their vitamin B₁₂ and B content. One preparation contained no B₁₂ but showed marked activity in vitamin B deficiency in rats. The authors assert that the extrinsic factor described by Castle is not identical with vitamin B₁₂ or with any fraction of the vitamin B complex. Yeast either has no antianemic efficiency or possibly contains minimal quantities of the antianemic factor. No increase in the amount of active principle by the addition of normal gastric juice was definitely established.

*Investigations on Fermentation of Galactose in Bauer's Liver Function Test T. Geil—p. 404

Investigations on Fermentation of Galactose in Bauer's Liver Function Test—In Bauer's galactose test in a number of cases Geil determined the sugar content by fermentation and by polarization. He reports that the agreement in the results obtained confirms that the saccharide eliminated in the liver function test is really galactose and that polarimetric determination after preliminary treatment with acetic acid and animal charcoal gives exact values.

*Fatal Case of Silicosis S. V. Gudjonsson and C. J. Jacobson—p. 423
*Erythrophagia in Circulating Blood Two Cases J. Engelbreth-Holm—p. 431

Silicosis Fatal Case—On microscopic examination of lung tissue and of ash from lung tissue in a typical, uncomplicated case of silicosis in a porcelain turner Gudjonsson and Jacobson found numerous mineral needles resembling kaolin. The results are thought partly to support W. R. Jones's theory that silicosis is due to fibrous minerals and to show that kaolin probably can act like serecit.

Erythrophagia in Circulating Blood—Engelbreth-Holm ascribes erythrophagia in the circulating blood to injured or foreign erythrocytes in the blood stream, infections especially endocarditis lenta, or splenectomy. In his cases of transient erythrophagia in patients with eczema and tuberculous lymphoma respectively no pathologic cause of the erythrophagia could be found and the possibility is suggested that in rare instances erythrophagia may occur normally in the circulating blood.

Agranulocytosis in Patient Treated with Amidopyrine Case B. Larsen—p. 430
Amidopyrine Exanthem Without Changes in Blood Case P. Hansen—p. 431

Sinus Arrhythmia and Adams-Stokes Syndrome—Thomsen believes the arrhythmia in his case to be due to a partial disorder of the sinus node. He calls attention to the fact that the Adams-Stokes syndrome is not exclusively connected with atrioventricular block but can also occur with sinoauricular block and with sinus arrhythmia usually regarded as innocent disorders.
